The consumers also struggled to recall when and where some of their purchases were made, which was a problem as you would not know how old the product is, or where to place the complaint if needed, as described by Edgar (40M): *When you have no idea where you bought this particular bodysuit. Then, how do you complain? Yes, I do have a receipt for a bodysuit, but for which one? I don't bloody know. Then, you just don't. It doesn't work.*

Defects that are a result of wear and tear or because of improper or abnormal use are not considered to be deficiencies covered by the Consumer purchases act (Torgersen, 2020). This makes it more difficult to know when there is a legitimate ground to complain. Further, the legislation specifies that the complaint should be placed "within a reasonable time" after the defect should have been discovered. This reasonable time is considered to be two months and can be passed for example when the product is not taken into use right after the acquisition, or when the defect comes gradually, and the consumer does not react to the first signs.

### *Burden of proof*

Our material also revealed examples of cases where rightful complaints were not accepted, and the seller was not aware of the burden of proof aspect. Betty (48) talks about three tops that she purchased (Figure 1):

Betty (48F): *I bought three tops this summer, used one of them and when I washed it, it shrank. The washing instructions said 40 degrees, I washed it at 40 and had to stretch it on both sides but is remained too short. I went back to the shop and received a new one. But the same thing happened to all of them. Then, when I came back and told them, they didn't believe me. It was me who had done it wrong… thought I'd washed at 60 and... They should last more than one wash.*

The seller has the burden of proof for any faults that become apparent within 6 months of the item being delivered, while the consumer has to prove that the fault can be traced back to the time of purchase if the defects become apparent after the 6 months. Betty's tops were less than 6 months old, so the seller would have needed to prove that Betty had washed them wrong.

**Figure 1. One of Betty's shrunken tops.**

### *Materials and receipts*

The three studied product groups vary in size, weight, volume, and price, which all have consequences for the potential complaint process. Many of the participants showed they had some expectations base on price and brand, as well as materials. In general, the expectations of the length of product lifetimes have decreased (Gnanapragasam et al., 2017). This seems to influence textiles the most:

Astrid (39F): *Also everything has a certain lifespan. It's textile, and a garment, so it's not supposed to last for ten years, I think. […] Because it is a textile that you wear, that you stretch and bend [….] It is living, fibers and materials.*

Aksel (72M): *It is a bit strange, but that might be because I don't buy much [clothes], I can't see what… you don't really consider complaining* *when dissatisfied, you just think that you did a mistake purchase and get rid of it.*

Having to take care of receipts was a recurring problem for our informants:
Clara (76F): *Another problem with paper receipts, they…*
Cate (44F): *Loose colour*
Clara: *…tend to disappear (other participants affirm). Even if they are kept in paper envelopes, are in a plastic folder or whatever, the text disappears*.

Electronic receipts can solve many of the problems related to paper receipts, but they have their downsides too:
Emil (37M): *things have turned a bit simpler now, as they register things on you; asking for the phone number or e-mail and such, so it is... They save the receipt for you. I haven't quite figured out why they bother to do that?*
Edgar (40M): *It is just as much about them wanting to know as much as possible about you, so that they can customize and send more advertisements for you, and see that "this fellow previously bought similar things, he might fall for this offer". That's what it's all about.*

## Conclusions
Strengthening and extending consumer rights to complain is an important part of the strategy to increase the quality of goods and extend their lifetimes. It is both an important avenue for businesses to gain information about the performance of their products, and for legal durability expectations to be enforced. The findings show barriers and opportunities to the efficacy of this strategy that is highly relevant for policy development.

Our findings show how the complaint process should be made easier for the consumers, so that the transaction cost of using time, effort, and money, as well as related uncertainty, is reduced. The uncertainty of the outcome can be reduced through several measures, including clear guidelines on what the consumer rights are for the specific products (two or five years), what is considered acceptable and unacceptable abrasion during normal use, information about the seller having the burden of proof responsibility for the first six months, and clear information on the benefits of commercial warranties that may come in addition to the legal rights.

The instructions concerning the applicable rights should be made clearer not only for consumers but also businesses, and in case of disagreements, information on how to proceed so that they can be mediated by consumer organizations.

In addition to clearer guidelines, there are possibilities for new technical solutions to facilitate the storage of receipts and purchase information related to each product, which was especially problematic for low-priced items that the consumers had many of. Digital product passes may be developed with this in mind, and could also include information about consumer rights.

# Clothing care practices: from an LCA perspective

**Letien, E. [(a)], Benkirane, R.[(a)], Pichon, N.[(a)], Perwuelz, A.[(a)]**
a) Univ. Lille, ENSAIT, ULR 2461 - GEMTEX - Génie et Matériaux Textiles, F-59000 Lille, France

**Keywords**: Clothing; Care practices; Laundry; environmental evaluation; LCA.

**Abstract**: The Fashion-related value chain is complex and globally spread. It is well known that the textile sector generates tremendous environmental impacts that are fairly well distributed throughout the life cycle of textile articles. Considering the consumer's influence on design or end-of-life choices is limited, he/she remains a fundamental actor in the life cycle of a garment: the use phase being under its full responsibility. Use commonly refers to the wearing and caring for clothes (including washing, drying and ironing). In recent decades, care solutions have largely evolved and now tend to respond to increasingly specific needs. In this sense, the laundry care scenarios are much more diversified and the associated environmental impacts become more difficult to evaluate. In this article, a non-exhaustive literature review is proposed to outline the available solutions of textile care. It covers washing, drying and ironing technologies as well as detergents. By roughly considering these four axes, hundreds of cleaning scenarios are identified. Some are then covered in environmental evaluation that involves primary data collection and life cycle assessment. About 30 different cleaning scenarios are modelled to investigate an overall dispersion of impact results. Huge differences are observed. In a critical global context (considering resources), it should question the future cleaning practices.

## Introduction

The Fashion-related value chain is complex and globally spread. Due to high resource consumption, the textile sector, including clothing, footwear and household textiles, has the fourth highest environmental impact of all categories of EU consumption and the fifth regarding greenhouse gas emissions (Christis et al., 2019). It is estimated that Fashion is responsible for approximately 3% to 8% of global anthropogenic carbon emissions (Niinimäki et al., 2020; Quantis, 2018) and it is of interest to notice that these emissions are quite equally distributed between both the production and use phases (Benkirane, 2019; Beton et al., 2014; Sandin et al., 2019; Steinberger et al., 2009). Thus, manufacturers and consumers have the possibility to contribute to reducing the environmental impact. However, both must be guided, in order to promote more responsible practices, such as renting, updating, repairing, longer lifetime product (Niinimäki et al., 2020). In this study, a focus is made on the use phase and specifically on the cleaning phase with the aim to identify the associated hotspots.

Considering the consumer's influence on design or end-of-life choices is limited, he/she remains a fundamental actor in the life cycle of a garment. The lifetime of products is partly under his responsibility and has a significant incidence on the environmental impact (Benkirane et al., 2016; Cooper, 1994; Cooper & Claxton, 2022; Leffland et al., 1997; Sandin et al., 2019).

The use phase commonly refers to the wearing and caring for clothes. Care refers to the washing, drying and ironing steps (Laitala et al., 2018; Wiedemann et al., 2021) and is necessary for keeping clothing functional and acceptable (Klepp, 2007; Shove, 2003). Ultimately, the use-related environmental impact is influenced by the product lifespan and the consumer behavior and it is induced by the washing frequency, the wash temperature, the detergent used and the drying method (Beton et al., 2014; Ellebaek Larsen et al., 2007; Steinberger et al., 2009).

More in depth, the environmental impacts of the use phase originate from water, energy and chemicals consumption and from chemicals and micro-plastics release. All being detrimental on greenhouse gas emission, freshwater and marine toxicity (Christis et al., 2019; Sajn, 2022). According to a report from bigEE, an international initiative coordinated by the Wuppertal Institute, about 840 million domestic washing machines were enumerated worldwide in 2013 (bigEE et al., 2013). Corresponding in total to an estimated electricity consumption of 92 TWh and an estimated water consumption of 19 billion m$^3$ (bigEE et al., 2013). At the European scale and according to the Commission Regulation of 2019, these annual energy and water consumptions were estimated (in 2015) at 35,3 TWh and 2 496 million m$^3$ (Commission Regulation, 2019). At a French scale and according to a French measurement campaign (Enertech, 2016):

- the average electricity consumption of a washing machine in a French household is 92 kWh per year (in 2016), a 45% reduction compared to 2008
- the average electricity consumption of a dryer in a French household is 199 kWh/year, a reduction of 47% compared to 1995-1996.

It reflects considerable improvements in the efficiency of washing machines in recent decades. However, the reduction of environmental impacts from laundry was shown to be hampered by the consumer habits (Laitala et al., 2011). It appears that changing consumers' cleaning practices, especially laundering frequency is the best opportunity for improvement with respect to the environmental impacts of cleaning (Laitala et al., 2020).

Textile care solutions have largely evolved. The variety of products (washing machines, dryers, detergents ...) is much wider, each of them responding to increasingly specific needs. In this sense, the laundry care scenarios are much more diversified and to the best of our knowledge, no study has yet enumerated the current options offered to consumers for the care of their laundry.

In the following, a non-exhaustive literature review is proposed to outline the available opportunities in the world of textile care. It covers washing, drying and ironing technologies as well as detergents. By simply considering these four axes, the complexity of care is seen to be quite significant. Thus, to support the change of cleaning practices, it appears necessary to educate the consumer on the care of their textiles.

## Literature review

### *Washing process*

Washing clothes is one of the most common housework in the world. Washing aims to provide hygienically clean laundry, to preserve its value (Pakula & Stamminger, 2010) and to maintain its functionality and acceptability (Klepp, 2007; Shove, 2003). The domestic washing process has changed: from a manual to an automatic process. Using water, electricity, chemicals, washing machines enable consumer to avoid a mechanical work of cleaning textile products. However, substantial differences in consumption can be observed around the world. Considering that:

- the heterogeneous distribution of domestic washing machines in the world,
- the types of machines and their efficiency levels
- the wash habits and practices (e.g. wash temperatures, number of wash cycles per year)

it is estimated that (bigEE et al., 2013):

- 29% of direct electricity consumption from washing machines comes from Western Europe while it is only 1% in Sub-Saharan Africa
- 20% of water consumption for domestic washing machines comes from North America, 9% from Western Europe and only 1% from Sub Saharan Africa.

These findings are driven by the distribution of domestic washing machines, which is very unequal across world regions. In North America, Western Europe, and the OECD Pacific region, most households own a washing machine, while in other parts of the world the ownership rate is much lower (bigEE et al., 2013).

Considering that, in France, 97% of French people have a washing machine in 2019 (Gifam, s. d.-a), the variability in energy and water consumptions should come from consumer and technological aspects. Both being considered in the study of Shahmohammadi et al.. The study mentions two category of choices, related to the consumer and to the manufacturer; it includes parameters such as: the washing machine type, efficiency and size, the available programs, the loading, the detergents, … (Shahmohammadi et al., 2018).

Based on both, scientific and grey literature, domestic washing machines can be classified in three categories: according to the washing method or according to the vibration system (Table 1). These three categories are also listed in the NF EN ISO 6330 standard, which covers domestic care procedures for textile testing specifically.

| ISO 6330 | Washing method | Vibration system |
|---|---|---|
| Type A, horizontal axis, front-loading | Drum | Horizontal-axis |
| Type B, vertical axis, top-loading agitator type | Agitator | Vertical-axis |
| Type C, vertical axis, top-loading pulsator type | Pulsator | |
| | Washer dryer | |

**Table 1. Types of washing machines (AFNOR, 2021; Gifam, s. d.-a; Katayama & Sugihara, 2011; Lim et al., 2010)**

*Detergent*

Laundry detergent is a substance that is added when washing clothes to help make them cleaner. As said by Lai et al. "cleaning performance is a function of concentration and type of active ingredients that are delivered into the cleaning bath" (Lai, 2006). Since there is no universal detergent formulation, the topic should be considered as highly complex. The detergent used depend on the habits of the consumers, on the nature of the washed textiles as well as on the nature of the stain to clean (Bajpai & Tyagi, 2007; Nardello-Rataj & Ho Tan Taï, 2006). Indeed, the formulation of a detergent for textile articles is based on the identification of the dirty articles, their composition, the origin and the nature of the soiling. A detergent contains one or more surfactants formulated with other components to enhance detergency (Lai, 2006). Its formulation requires the identification of all ingredients and processes that can be used to eliminate various types of soils. Depending on the formula, each ingredient will provide a complementary function (Table 2):

- to clean as a main function
- to preserve the softness, to restore the brightness of the colors, to prevent the color transfer …
- enable a fresh smell, respect of the environment...

| Ingredient category | Function |
|---|---|
| Surfactant | Removal of soiling |
| Anti-scaling agent (builders) | Soften the water |
| Bleaching agents | Removal of colored stains or light soiling |
| Enzymes | Removal of biological stains |
| Hydrophilic polymers | Redeposition inhibitors |
| Defoaming agents | |
| Optical brighteners | "Whiter than white" |
| Perfumes | |

**Table 2. Examples of ingredient of detergent (Bajpai & Tyagi, 2007; Nardello-Rataj & Ho Tan Taï, 2006)**

All detergents are generally available in solid form (powders, tablets) or liquid form (concentrated liquids in gel form and pre-dosed capsules). In addition, it is still possible to add a softener (softener is not considered in this article).

*Drying process*

After washing, the laundry must be dried before it can be stored and used. In France, only 34% of French households own a tumble dryer (Gifam, s. d.-b). The majority of households therefore dry their laundry in the open air. According to scientific and grey literature, three types of dryers exist (Table 3).

| ISO 6330 | Drying technology |
|---|---|
| Type A1, Tumble dryer, vented | Tumbler dryer – vented which remove moisture from your clothes and vent out the produced steam. |
| Type A2, Tumble dryer, condenser | Tumbler dryer – condenser (in open and closed cycle) which remove moisture from your clothes and collect it in a tank |
| - | Tumbler dryer - heat pump which enable hot air that is created inside the drum to circulate and to dry clothes. |

**Table 3. Types of tumble dryers (AFNOR, 2021; Bansal et al., 2001; Gifam, s. d.-b; Yadav & Moon, 2008; Yu et al., 2020).**

The condensation dryer and the heat pump dryer work in a closed circuit, i.e. the water contained in the wet laundry is recovered by condensation. The only difference between the two appliances is that the condensation dryer uses a heating resistor that cools the water vapor and transforms it into a liquid state, unlike the heat pump dryer which has no resistor and uses the heat of the water vapor to dry the clothes. The heat pump dryer saves a lot of energy with this method. Finally, vented dryers vent moisture from textiles outside the home. Therefore, an exhaust duct must be provided. It should be noted that these appliances are very energy consuming. Finally, regardless of the type of dryer, the lint filter must be cleaned after each use so that the air circulation in the appliance is optimal and thus have maximum drying. Each dryer has several programs. Generally, there are three types: ready to iron, ready to store, and ultra-dry. It should be noted that the "ready to store" program contains less residual moisture (between 0 and 3%) compared to 12% for the "ready to iron" program. These different programs influence the consumption of the appliance. The consumption of the dryer is energy only. In addition, water and textile fibers are recovered.

*Ironing process*

Ironing consist in removing wrinkles of textiles. It usually involves the use of a heated tool and the use of steam. The delivery of a wrinkle-free surface is related to three key parameters: temperature, relative humidity, and pressure (Benusiglio et al., 2012; Liang et al., 2018). Based on grey literature, four types of ironing equipment (Table 4) were identified:

| **Ironing equipment** |
|---|
| Steam iron |
| Central steam |
| Ironing centers |
| Vertical steamer |

**Table 4. Ironing technologies (Gifam, s. d.-c).**

Today's irons are steam irons, they differ from central steamers because the latter have tanks that can hold several liters of water, which allows you to iron large quantities of laundry at once. Above all, they produce a quantity and a pressure of steam more important. On the other hand, the ironing centers are ironing tables with an integrated steam central and the steam ironer that allow to straighten a garment vertically (without pressure).

*Literature conclusion*

Considering the existing types of washing machines, of detergents, tumble dryers and ironing equipment (Figure 1), it becomes possible to enumerate about 500 possible cleaning scenarios for clothing. However, it still underestimated as the washing, drying and ironing programs are not considered as well as the detergent formulation. As mentioned earlier, the textile care solutions tend to respond to more specific needs and the variety of machines programs and detergent formulation increase. In average and based on French grey literature (i.e. machine documentations), 8 programs count be counted for washing machines, 3 for drying machines and 3 for ironing. It becomes reasonable to consider thousands of cleaning scenarios for textile.

**Figure 1. Possible cleaning scenarios.**

Considering even these hundreds of textile care scenarios, it becomes essential to identify the minimum and maximum limits of environmental impacts related to this phase of use.

## Method

To contribute in such an overview, protocols were set up to wash textile articles and to collect detergent, energy and water consumptions. These protocols were set up on the basis of the standard (NF EN 60456):

- 5 kg load in the washing machine
- use of ballasts if necessary
- storage of items in a controlled atmosphere room
- Precise 25g scale for weighing the laundry
- 27g+8g/kg of detergent (depending on water hardness)
- 2 available washing machines(A+++)

Consumption measurements were taken with a power meter, weighing the various water tanks and weighting the fiber release when it was possible. Finally, 2 washing machines, 1 tumble dryer, 2 steam irons and 1 steam central were tested in the process. Based on these measurements environmental evaluations were carried out using life cycle assessment methodology (LCA) (AFNOR, 2006). About 30 cleaning scenarios were considered in this analysis.

## Results

*Data collection: flow measurements*

Given the number of measurements, an overview of the measurements is here proposed. The Figure 2, Figure 3 and Figure 4 are related to the washing process. They represent the consumption of detergent (g/kg), energy (kWh/kg), and water (L/kg) respectively. All these measurements were collected through 12 programs considering the following parameters:

- Temperature (20, 40 and 60°C)
- Load (3, 4 and 6kg)
- Specified composition (cotton, synthetic)
- Eco, white/color parameters

The Figure 5, Figure 6 and Figure 7 are related to the drying process. They represent the consumption of energy (kWh/kg) and the water (mL/kg) and fiber (g/kg) release respectively. These measurements were collected trough three programs (ready to store, normal and ready to iron), load from 2 to 6kg.

**Figure 2. Detergent measured quantity.**

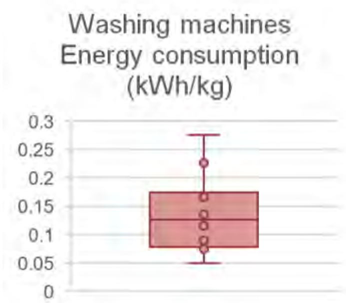

**Figure 3. Washing machines energy measurements.**

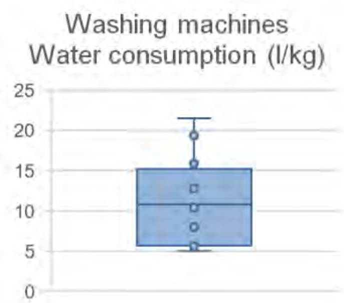

**Figure 4. Washing machines water measurements.**

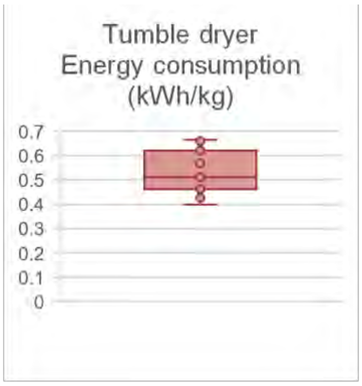

**Figure 5. Tumble dryer energy measurements.**

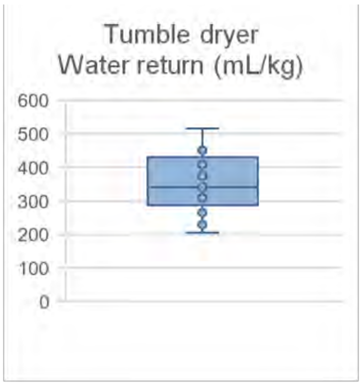

**Figure 6. Tumble dryer water return measurements.**

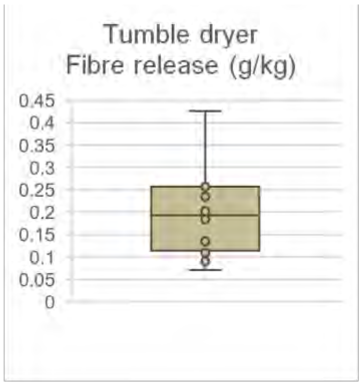

**Figure 7. Tumble dryer fibre release measurements.**

Finally, the Figure 8 and Figure 9 show the consumption values obtained during the ironing process. Both, the steam irons and the steam central are made visible as they are two different technologies. Measurements from the ironing process includes synthetic, cotton and flax program (i.e. from the lowest to the highest temperature).

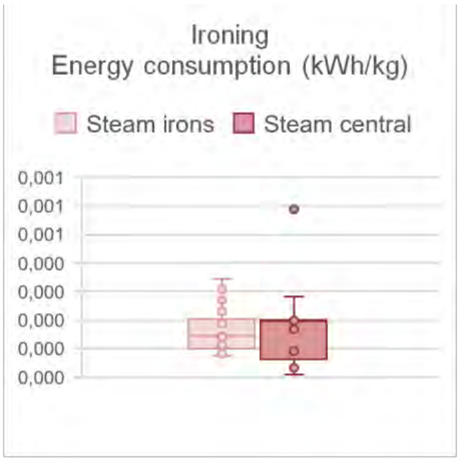

**Figure 8. Irons energy measurements.**

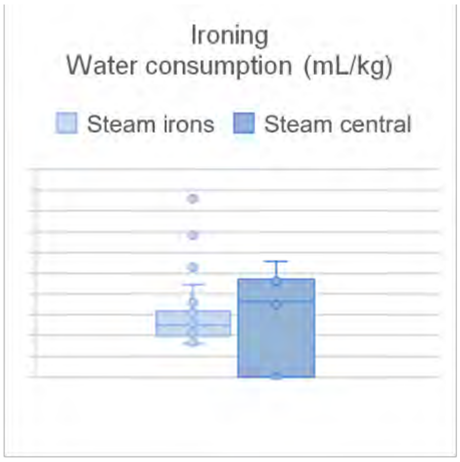

**Figure 9. Irons water measurements.**

From this data collection process, it is interesting to notice the global dispersion of measurements. As an example, the fiber release observed during the drying process is very variable. Also, some outliers can be observed in the box plots of both the ironing energy and water consumption (i.e. these measurements are individually not representative of all the points).

*Life Cycle Assessment*

The cleaning scenarios simulated for the environmental assessment are distinguished by the machines they involve, the programs used, and the detergents used. Thus, 2 washing machines, 2 ironing devices are considered; 4 washing temperatures in combination with 4 load capacities; 3 drying and 3 ironing programs as well as 4 detergent formats and 1 softener. The possibility of not drying and not ironing is also considered. The thirty or so simulations do not aim to be exhaustive, but rather to assess some extreme cases and their influence over time:

- 7 washing scenarios,
- 10 washing and drying scenarios,
- 14 washing, drying and ironing scenarios.

To adopt a fairly inclusive perspective of the cleaning processes, a generic functional unit is used: "cleaning 1kg of laundry".

The characterization of the impacts is done using the ILCD 2011 Midpoint+ V1.11. It covers environmental indicators such as: climate change, ozone depletion, human toxicity, particulate matter, ionizing radiation, photochemical ozone formation, various eutrophication, ecotoxicity or water resource depletion.

As expected, the best scenarios are those which include a minimum of processes and materials (the 7 washing scenarios) while the worst include a maximum of processes. The very best scenario is a 20°C synthetic washing program with powder detergent. The worst scenario is a 60°C Cotton washing program in addition to a "Ready to iron" drying program and the highest temperature of a steam iron.

However, rather than proposing a point-by-point analysis, it seems interesting to investigate the overall dispersion of impact results to see what the consequences are. To do so, as in the previous section, an example of the results is shown in Figure 10, in the form of a box plot. It represents the dispersion of the results obtained on the water resource depletion indicator. It appears that 50% of the scenarios are present between 0.004 and 0.006m$^3$. Meanwhile, a factor of 3 can be observed between the minimum and the maximum values.

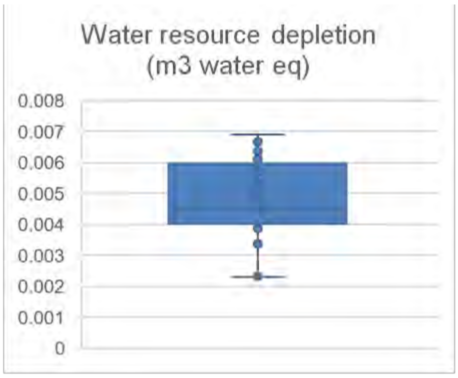

**Figure 10. Dispersion of the results obtained on the water resource depletion indicator.**

The factors observed with regard to the other impact indicators range from 3 (water resource depletion and human toxicity) to 20 (ionizing radiation).

When considering the environmental impacts of the use phase, the more items are cleaned, the higher their impacts. However, given the factors just mentioned, it is clear that between two cleaning practices, the difference can quickly increase. As an example, Figure 11 and Figure 12 illustrate the cumulative impact on the climate change (best vs worst scenario factor is 6,6) and on freshwater ecotoxicity (best vs worst scenario factor is 8,4) respectively. Each curve represents one of the 30 cleaning scenarios, the whole being framed by the minimum and maximum observed. It is clear that the worst scenarios related-impacts increase faster as well as the difference with the best scenarios.

In a global context where the issue of water and energy resources is becoming increasingly critical, it is clear that it will be necessary in the long term to focus on cleaning practices that are less harmful to the environment.

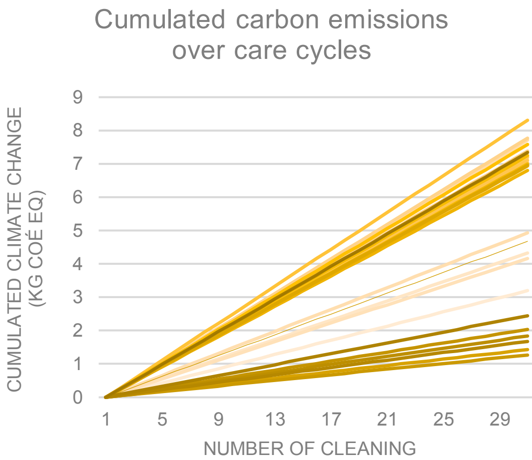

**Figure 11. Cumulative carbon emissions from 30 scenarios over the care cycles.**

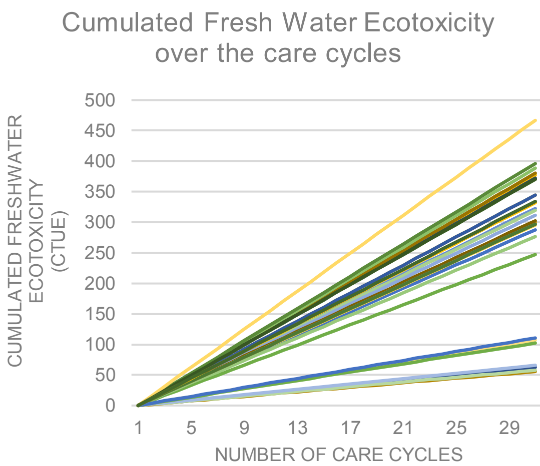

**Figure 12. Cumulative Fresh Water ecotoxicity from 30 scenarios over the care cycles.**

## Conclusions

In this study, a focus is made on the cleaning phase of textile with a focus on the washing, drying and ironing technologies as well as on the detergent. Altogether, more than 500 cleaning scenarios for textile were enumerated. Given such a high number of opportunities it appears fundamental to identify the environmental impacts limits of these scenarios to better frame the recommendations for the consumers. Based on literature and standards, protocols were set up to wash textile and collect detergent, energy and water consumption. Life Cycle Assessment methodology was use to evaluate environmental impact of about 30 different cleaning scenarios. From these evaluations, the overall dispersion of impact results was investigated. It appears that the consequences between the extreme scenarios are from 3 to 20 times higher according to the impact indicator considered. The study is based on measurements of consumption and is not exhaustive. It is reasonable to think that more extreme scenarios are to be considered. Moreover, it could be interesting to integrate the processes resulting from the DIY with hand washing, homemade laundry, even lavomatics, dry washing etc...

One question remains to know which scenarios are really used by consumers. For example, out of 8 programs on average on machines sold in France, are they all really used? As it has been said by others, the consumer relies on his habits to care for his clothes. Therefore, it is legitimate to question the maximum number of programs used by consumers. To go further, it would be appropriate to consider the consequences of the washing on the clothes.

# Narratives of product longevity: a business vs. consumer perspective

**Lisbeth Løvbak Berg** [(a)], **Marie Hebrok** [(a)]
a) Consumption Research Norway (SIFO), Oslo Metropolitan University, Oslo, Norway

**Keywords**: Narratives; Consumer behaviour; Design strategy; Production volumes; Durability.

**Abstract**: This paper explores narratives of product longevity expressed by businesses and consumers, with the aim of illuminating and comparing ways in which the two stakeholder groups express their engagement with products in the context of prolonging their lifespans. We base our analysis on consumer focus groups and interviews with company representatives. Our focus is on textiles (incl. clothing) and furniture. We find that technical and emotional durability are the two dominant ways of understanding product longevity by company representatives. Consumers, however, tell a different story, of living with their things, of use, of time passing, and of life events triggering change. This is a context in which social and systemic factors play a large role in determining the lifespan of a product – factors that are external to the product itself. Although all can agree on the importance of technical durability, problems connected to excessive production volumes and how products feature in everyday life are avoided in narratives produced by business actors. We argue that corporate narratives of product longevity are diverting our attention away from production toward consumption, keeping questions of volume and growth at arm's length. These conflict with consumer narratives of product longevity that grapple with the materiality of the things within the context of lived lives in a consumer economy.

## Introduction

Product durability has become one of the main selling points for businesses promoting themselves as sustainable. It has become widely recognized that, although important, the technical durability of products is often not the deciding factor for decisions of disposal (Laitala & Klepp, 2022; Evans & Cooper, 2010). With the publishing of the book entitled Emotionally Durable Design by Jonathan Chapman in 2005, the belief that emotional attachment could be embedded into products to prolong their lifespan became incorporated into design strategies applied both in companies and in design education. As such, it is an idea that has become part of the narratives of product longevity and sustainable production and consumption more broadly.

Narratives are produced through collective efforts to create coherent understandings about who we are and how we act (Barthes, 1975). Present narratives about sustainability are dominated by ideas of green growth and circular economies (EC, 2020; UN, 2022). These narratives influence how all actors in society think and act. For instance, what production companies consider to be sustainable production, and what consumers consider to be sustainable consumption. This again directs resource extraction, production, marketing, and consumption practices. Thus, it is of great importance to shed light on specific layers of narratives as they are invoked by both business actors and consumers.

## Theoretical and methodological approach

The analysis distinguishes between small n-narratives (personal experiences), big N-Narratives (themes supported by the n-narratives) and Master Narratives (cultural ideology driving the narratives) (Tannen, 2008), exposing the layered nature of the construction of collective narratives about product longevity and sustainability.

The analysis is based on data material from six focus groups with Norwegian consumers, of both genders (17 men, 19 women, ages 22-76) conducted Nov/Dec 2021, and 9 semi-structured interviews with representatives from 4 furniture companies and 5 clothing companies in Norway, ranging from start-ups to big scale companies, specifically selected for their focus on extending the lifetimes of their products. The interviewees were company representatives in positions such as sustainability manager, designer, founder, CEO, CFO, creative director, and marketing director.

Participants in the focus groups were recruited through the agency Norstat. Before the focus groups, the participants were asked to submit photos of products they like and have had for a long time or conversely, that they dislike and have only owned for a short period. These photos were used as prompts during the conversations and elicited concrete product stories along with more general questions about the acquisition, use, and disposal of the products.

The focus groups and interviews were transcribed and coded inductively. Quotes are presented with pseudonyms and ages.

## Results

We analyse the responses from the interviews and focus groups as narratives that the representatives are constructing to respond to questions about product longevity, and that consumers are constructing around how products are involved in their everyday life.

### *The business narratives: the lives of products*

The interviewed businesses view product longevity to be determined both by factors related to the technical durability of materials and construction, as well as the emotional durability of aesthetics, and function.

*(...) our primary goal is to make our products last for a long time, preferably for generations. A part of that concerns the choice of materials and that things are built to endure the intended use, and that people do not get tired of them very quickly and choose to replace them. (Kitchen manufacturer)*

Emotional durability is a well-recognized aspect of product durability amongst the interviewed businesses, primarily addressed through storytelling and transparency. Transparency most often concerns the value chain of the products, showing and being honest about where materials come from, how and under what conditions they are made, and how they are transported to the customers.

*What keeps your product in use for a long time? - I think it's the relationship with the production and our story. Being proud of the garment is the most important factor in making the garment last a long time. We use storytelling to show the production of the products, and we notice that as a result, the products get a higher value for the consumer. We invite people to the factory to walk around and talk to people in production. We want everything to be completely transparent, and we notice that it works. (Clothing company)*

Local craftsmanship is highlighted as contributing to both technical and emotional durability, by ensuring certain qualities related to material and constructional strength, local identity, and aesthetic timelessness. Furthermore, as described by the kitchen manufacturer below, the local aspect allows for a high level of personal service and building close relationships with customers.

*Craftsmanship has become equated to high quality. The materials in combination with the craftsmanship are decisive for the lifespan. When the customer journey begins we start a dialogue to understand who the customer is and what they need. Then we take them with us to the production facilities and show the craftsmanship, the materials, and how things are made. We lead the customer through a very different process than other kitchen manufacturers do, and that creates a completely different relationship with the product they end up with. (Kitchen manufacturer)*

Not succumbing to the ever-changing trends dictating the market is an ideal sought to achieve by upholding collections with minimal annual updates across decades. According to the businesses, the stability of such collections allows customers to upgrade, repair, and add to the products they already own, instead of replacing them with new ones.

*Our furniture is classic and they fit the collection and the style of our company, which means that you can mix and match more easily and can buy new products that fit together with the old. (Furniture manufacturer)*

Furthermore, the availability of spare parts, ways to upgrade existing products (e.g., new fronts, covers), the design of flexible furniture that can be used for multiple purposes, and services for multiple use and ownership (i.e., leasing, takeback, and resale) are strategies highlighted. The companies interviewed view the responsibility for ensuring longer-lasting products as divided between themselves and their customers. To help their customers they offer guidelines and services for maintenance and repair.

When asked about the apparent paradox inherent in both increasing product lifespans and the production and consumption of products, companies fall short in addressing the systemic problem of global production volumes and overconsumption. Their response to this is investing in services for multi-use and multi-ownership. Several companies argue that there is still room for their products on the market and that, from a sustainability perspective, their products should take market shares from less sustainable companies.

The businesses' small-n narratives are dominated by descriptions of how they work to ensure material and emotional longevity. The material longevity comes from using certain materials particularly robust and that are processed into products in such a way that the final product is also robust, and can withstand use over "generations", and from consumer education and maintenance and repair services. Emotional longevity, on the other hand, is something embedded into products mainly through storytelling about the supply chains, but also through the construction of identity through their brand and designs.
The big-N narratives that support these ways of doing are value driven and refer to what sustainable materials and value chains are, the advantages of local production, what constitutes high-quality products, and consumers investing in these values.

*We increasingly choose sustainable materials - recycled polyester, recycled wool, recycled down, and organic cotton. However, we would never choose poor-quality materials even if they are recycled - quality always trumps. (Clothing company)*

*I think there has really been a change in the consumer's way of thinking to appreciate more what they have and buy less fast fashion, buy less low price, and actually value good quality from local businesses and support what is Norwegian. (Furniture manufacturer)*

The n- and N-narratives draw from a Master-narrative that businesses should create sustainable, long-lasting products. This fits within the dominant imaginary of green growth where the significance of volumes is camouflaged by value-based narratives that focus on the "greenness" of materials and production, and romanticize products and businesses through storytelling.

### *The consumer narratives: living with products*

Stories and anecdotes of their practices and products that lasted or that didn't, dominated the consumers' small-n narratives. For both textiles and furniture, physical aspects like the material withstanding use, appearance and comfort mattered. In a few instances, the brand or perceived quality of the product was used as an explanation for why it had lasted so long. Adversely, the products that didn't last had lost their function or aesthetic appeal or had never fully had it.

For each product, the consumers were asked why they liked or were satisfied with it. The response was often simply that it had lasted - the duration of successful use had created a bond with the product. When they spoke of emotions it was as 'sentimental value' and related to personal history, often to someone they held dear. However, these products were also still largely functional.

A more surprising attachment was described by Freya (45) to a simple, mass-produced, two-step wooden ladder (Figure 1), that had been used for everything from its intended use to an extra table and even home exercises during the Covid-18-pandemic, and could be sanded down and repainted when needed. As such, it posses the *"evolutionary capabilities, enabling a co-evolution with the user"* without which *"we will forever be growing a landfill of discarded objects whose only crime was failure to keep the story alive"* that Chapman (2005, p. 120) discusses, but not in a way predictable by a designer.

**Figure 1. Freya's favourite piece of furniture.**

The way the consumers contrasted these successful and unsuccessful product stories revealed the M-narrative that "things should last" and other connected narratives that followed them from acquisition, throughout use, to disposal. The big N-narratives of why they do things displayed the ideal product practices, e.g., of holding on to our things:

*[…] I have given away too many things. I've moved too many times in life so all the nice things have gone and old clothes to Fretex (the Salvation Army) and… […] (Cate,44)*

The consumer stories show that durability is much more complex than the linear process of acquisition, use and disposal, and dependent on factors external to the product itself. Holding on or letting go of a product as such became a negotiation between the volume of possessions and space/storage, life events such as moving and having children, price and resources, conscience, etc.:

*Moved in June, then I bought a pretty expensive sofa and already found a chocolate stain after the kids. I've just realised that it will get worn, it doesn't matter. Change it in 5-6 years. (Emil, 37)*

The process of letting go often takes time and involves several steps, such as storing the item or moving it to a secondary location - a cabin or a less important room - before disposal. For clothing, this involves uses in less visible ways, underneath other clothes or at home, or doing manual labour. These steps are enabled by the material conditions of the consumers' lives and are easier to manage later in life when one's living space(s) were larger, like how David (57) described that they "*'re also so lucky as to have a garage, and then there's no room for the car in the garage (…)"*

The M-narrative that "you shouldn't waste things" is evident in both Cate's and David's quotes above. But in many cases, things are wasted, or not kept. Likewise, things are not always bought to last.

The general trend was, however, accumulation, and letting go was, therefore, a necessary result of acquiring more "stuff" - when something comes in, something has to go. Here younger informants more often contributed to lifetime extensions through inheriting items or buying second-hand, while older informants expressed sorrow and guilt for already having accumulated so much they could not inherit anything more:

*… a mother that is 96 […] every time I'm home she "You can… do you want this? [...] that?" They have cupboards and drawers bursting and it's sad to have to say "No. No. No." all the time because we don't have room for another cup in the cupboard anymore. (Douglas, 62)*

Overall, in their accounts of dealing with their various possessions - clearing out, gifting, reselling - there was a clear narrative stating that "we should buy, have and throw away fewer things". The guilt, sorrow and negotiations related to throw-away consumption also showed through the preference for modes of disposal that enables re-use. When Benny (66) said *"[t[hat they're starting to talk about us keeping things for longer. You don't just produce and produce, and discard and discard and discard and discard",* he also pointed directly to the producers – increasing lifetime should lead to lower production.

## Discussion

As recognised by both company representatives and consumers, technical durability is a good start when seeking to prolong the lifespans of products, but not enough. Emotional attachment has been identified by the design profession as the magic ingredient for keeping products in use, and companies have attempted to embed it into products through storytelling. However, seen in the light of the present challenges of overproduction and waste mountains, this is also ineffective. When comparing the present narratives conveyed by business actors and consumers, it becomes evident that emotional attachment cannot be embedded in products by companies. Our findings suggest that, while the efforts to embed emotional durability into products may enhance brand loyalty and help consumers make product choices, it is the products that last and are used that become emotionally durable. Chapman (2005, p. 118) describes this beautifully in his example of the teddy bear: *"narratives of this intimate nature cannot be purchased and the many layers of emotional investment embedded in the old bear are impossible to replace or simulate".* Technical durability is significantly impacted by circumstances in the consumers' lives, which further limits the influence of the producer. As found by Fletcher (2012, p. 222) in the context of clothing; "*garments which defy obsolescence do so in informal or unintentional ways, rarely as a result of design planning or material or product qualities".*

The Master-narratives conveyed by both businesses and consumers focus on the importance of products lasting. However, businesses focus only on their own products, while consumers have to relate to all products. The interactions between different products and all other factors that are evident in their large-N and small-n-narratives are therefore lost in the business approaches. Changing life phases and life events greatly influence and, in many cases, shorten the lifespans of products (Hebrok, 2016).

The dominant narrative of long-lasting products as an effective way to reduce consumption is being challenged by recent research that has found that the connection between increased product lifespans and reduced production volumes is weak. Furthermore, the potential benefits are negated by the volumes of new products being put into the world (Tham & Fletcher, 2019; Maldini, 2019; Zink & Geyer, 2017). In this perspective, the narratives conveyed by businesses about technical and emotional durability function to conceal the fact that it is the issue of volumes, not durability that is at the core of sustainable solutions for production and consumption.

## Conclusions

We have shown how companies and consumers convey both converging and diverging narratives about product longevity. They agree that products should last as long as possible and be made from durable materials. However, when it comes to ideas about and experiences of emotional attachment there are some notable differences. While companies put a lot of effort into storytelling, consumers describe attachment to develop over time and in actual use. The attachments that form have very little to do with storytelling and everything to do with personal experiences and relationships. In many cases, life events and circumstances also hinder this process. Furthermore, the narratives created around what influences the lifespans of products, that are embedded within a larger socio-technical imaginary of green growth, contribute to concealing a disconnect between product longevity as a sustainability strategy and the negation of its effect through production volumes.

# Communicating the benefits of sustainable packaging: a discourse analysis of Big Food

**Natalia Lumby**[(a)]
a) Toronto Metropolitan University, Toronto, Canada

**Keywords**: Sustainability; Packaging; Returnable; Communication; Big Food.

**Abstract**: Packaging benefits such as protection, promotion and product delivery must be balanced with the waste packaging generates, especially in fast moving consumer goods like food where volumes are high. Sustainable packaging, and returnable packaging in particular, has the potential to reduce negative impacts. However, returnable packaging has seen limited scale-up, with ineffective communication being identified as an important barrier to consumer acceptance. This study evaluates how 8 large multinationals communicated about their packaging initiatives on their corporate websites. The challenges and enablers as well as the achievements and future goals these firms share are analyzed. The corpus has limited focus on returnable and refillable packaging systems, with a majority of the claims being about integrating recycling and recycled content. Here, partnerships are playing a key role in overcoming large scale challenges such as poor infrastructure. Brands are taking on different narratives (leader vs. victim) and using a balance of quantitative and qualitative claims when presenting their achievements, but are less likely to commit to numbers when setting future goals.

## Introduction

Packaging plays a critical role in the protection, promotion and successful delivery of products. It exists within a complex system, serving the needs of a number of stakeholders. In the food industry packaging often has a short life span within the home, thus increasing household waste. In a study interrogating food-take away, packaging accounted for 45-50% of the environmental impact (Li et al., 2020). The communicated solution is often recycling. Unfortunately, recycling cannot create a complete solution for packaging waste (Brouwer et al., 2020), as our consumption of natural resources continues to outpace our ability to replace them (Bocken et al., 2014). Focusing on recycling ignores the overproduction that is so common in fast moving consumer goods like food packaging (Muranko et al., 2021).

Given the limited ability of recycling to resolve material shortages in the long term, returnable packaging continues to be increasingly important (Ertz et al., 2017). Where typical production innovations to make greener products can have rebound effects (Druckman et al., 2011; Herring & Sorrell, 2009), a reduction in packaging required does translate to an overall materials reduction. With changing shopping behaviours post-pandemic, now is the time to understand and scale returnable packaging solutions.

Reusable packaging can deliver value to consumers through benefits such as reduction of waste from single-use packaging, which can also better align with the desires of eco-conscious consumers (Ertz et al., 2017). However, in order for a reusable packaging system to be effective, consumers need to shift their behaviour to new use patterns. If consumers treat reusable packaging as disposable, the environmental impact is negative because reusable packaging is made from more durable materials. Thus, understanding how brands are persuading consumers to adopt reusable business models, is a step toward improving the adoption of circular solutions.

Ineffective communication has been identified as a barrier to consumer acceptance for returnable packaging (Coelho et al., 2020). The purpose of this research is to interrogate if the benefits of sustainable packaging, with a focus on reusable packaging systems, in the food sector are being communicated with consumers and how. The study provides us with a descriptive landscape of how organizations are communicating about reusables.

Previous examples of studies in sustainability communication include the analysis of twitter feeds to evaluate the balance of triple bottom line claims (Mann et al., 2021), investigations of impression management tactics in sustainability reports (Sandberg & Holmlund, 2015), and analysis of GRI reports to analyze the impact of stakeholder pressure on transparency (Fernandez-Feijoo et al., 2014). In food specifically, researchers have evaluated the CSR reports of large multinationals and identified that they adopt a formal and distant style that lacks authenticity (Jindřichovská et al., 2020).

This study contributes to our understanding of how to make sustainability claims given an increase in consumer skepticism, especially from large organizations as a result of greenwashing (Farooq & Wicaksono, 2021). Greenwashing is an umbrella term used to describe the inflation of sustainability claims and efforts (Lyon & Montgomery, 2015). Greenwashing confuses consumers and can lead to a decrease in consumer trust, value, loyalty and an increase in perceived risk (Chen & Chang, 2013; More, 2019; Szabo & Webster, 2021). The problem of being perceived as greenwashing has even led to companies underrepresenting CSR efforts in an act of 'greenhushing', for fear of negative consequences (Font et al., 2017).

Some tactics identified by researchers as improving sustainability communication have been to align them with intrinsic motivations of the firm and be open about economic advantages (de Vries et al., 2015; Parguel et al., 2011). Further, using third party certifications for sustainability claim
s can also increase their trustworthiness (Gider & Hamm, 2019). All three of these tactics reduce skepticism. As a first step to evaluating communication tactics, this study uses a key source of discourse; company websites.
A description of the sampling and methods follows.

## Methods

This study is the first of several steps to investigate effective consumer communication practices for the successful adoption of returnable packaging systems. The purposive sample consisting of a group of companies referred to in food research as the "Big Ten" or "Big Food" were selected for this research. These companies, along with their subsidiaries, control 70% of food choice on the global market today (Hoffman, 2013). They include Nestle, Pepsi Co., Coca-Cola, Unilever, Kellogg's, Mondelez, Mars, Danone, General Mills, and Associated British Foods. The sample was selected due to the impact this group of companies have on the global food system. Successful scaling of returnable packaging by any one of these companies could start to transform the market globally. Two companies were then dropped from the sample as they did not have enough information related to packaging posted to draw any meaningful conclusions.

Given the specific interest in returnable packaging, the research began with an identification of examples of reusable packaging options offered by each of the organizations selected for the study. These examples were mapped to the four packaging types as defined by the Ellen McArthur Foundation (EMF). These types include refill on the go, refill at home, return on the go, and return at home (Lendal & Lindeblad Wingstrand, 2019).

Refill on the go describes options that allow consumers to bring their own container into retail. Refill at home are options where a refill is used to fill a parent container at home. Return on the go models have consumers return packages to a drop off point, and return at home offers collection from home services. Table 1 includes examples of each type owned by brands in the sample. This categorization is just one way of organizing the business models in returnable packaging. Other typologies, like the 4 types suggested by (Coelho et al., 2020) and the 6 types suggested by (Muranko et al., 2021) were also considered. Ultimately, the decision for this typology resulted from the strong presence of the EMF content on the websites of the selected brands.

| | Refill | Return |
|---|---|---|
| At home | • Soda Stream by PepsiCo<br>• Gatorade powders by PepsiCo | • Hellmann's mayonaise by Unilever<br>• Häagen-Dazs ice cream by Nestle<br>• Milka biscuits by Mondelez |
| On the go | • Bulk stores featuring Kellogg's cereal, M&M's by Mars or Danone yogurt<br>• Coca-Cola Freestyle | • Universal bottle by Coca-Cola Brazil |

**Table 1. Examples of four reuse models based on EMF framework.**

*All return at home examples are through a partnership with Loop, who also facilitates return on the go in select stores.

In addition to this descriptive analysis, an inductive qualitative study utilizing discourse analysis followed. Analyzing discourse is appropriate for this work as it is one way we can interrogate how social actors choose to influence their world (Keenoy et al., 1997). Further, looking at corporate social responsibility (CSR) communication is one way of understanding its meaning (O'Connor & Gronewold, 2013). For example, González et al. (2021) combined discourse analysis together with a survey to look at sustainability in alternative food organizations. Their research showed that different stakeholders carry different conceptualizations of sustainability; in their case food producers had a strong conceptualization while distributors had a weak conceptualization (González & Lorenzini, 2021).

This pilot study represents the start of a broader agenda to analyze all sources of discourse about reusable packaging for this important sample of organizations. To begin the work, company websites, and in particular their packaging sections were analyzed. Company websites are an important communication tool in the process of institutional change (Lemke, 1999) and they are commonly used to communicate about sustainability in the food sector (Jurado et al., 2018). They are a forum for discursive investigation about sustainability that requires more research (Higgins & Coffey, 2016). In addition, a descriptive analysis of reports filed with the Ellen McArthur Foundation were consulted for further information. Future sources of study will expand to include annual reports, sustainability reports, PR releases, and etc.

Themes in the discourse were identified following a protocol defined by Braun and Clarke (2006). As a first step, websites were imported into NVivo using the NCapture plug-in. Then the researcher familiarized herself with the data by reading and rereading the corpus. Second, with sentences as the units of analysis, general codes or categories of interest were inductively identified. This list of initial codes was organized into themes which were then reviewed and named (Braun & Clarke, 2006). Finally, a framework was developed to help sort the content into a more meaningful structure for interpretation.

**Figure 1. Framework for communicated claims for sustainable packaging.**

## Results and Discussion

The aim of this research was to understand how prominent food brands are communicating about their sustainable packaging options, with a focus on reusable packaging. In this first stage, an analysis of the overall sustainable packaging direction was analyzed. The results are presented in a framework consisting of challenges and enablers of sustainable packaging as well as the future goals and achievements of the organizations in the sample. Table 2 illustrates the frequency of each sub theme and theme, by organization

| | A | B | C | D | E | F | G | H | Total claims |
|---|---|---|---|---|---|---|---|---|---|
| **Achievements** | **12** | **11** | **23** | **7** | **3** | **9** | **26** | **10** | **101** |

| Technology | 0 | 1 | 1 | 1 | 0 | 0 | 5 | 0 | 8 |
| Circularity of materials | 0 | 1 | 0 | 2 | 0 | 0 | 3 | 0 | 6 |
| **Total Case Claims** | **26** | **19** | **49** | **20** | **8** | **31** | **125** | **41** | **319** |

**Table 2. Frequency of coded themes.**

Across the cases, the most prominent theme in the corpus was the achievements theme. This theme captured the number of instances an organization shared an achievement on their website. The theme consisted of three types of claims which included: designing for sustainability, waste reduction and wellbeing and safety. Designing for sustainability included concepts such as lightweighting, innovation in materials (for example bio-plastics), use of recycled content and the use of reuse or refill models. This indicates that these brands are largely using this media platform to communicate successful outcomes with stakeholders.

The breakdown of whether this achievement was communicated quantitatively and qualitatively was also coded. An even balance of each was found. The typical communication pattern was to build a qualitative narrative and then back it up with numerical data. Much of the numerical data shared is consistent with the reporting requirements to be a signatory with the Ellen McArthur Foundation (EMF). This is an example of how third-party organizations for reporting standards can be an effective way to reduce the risk of greenwashing (Villela et al., 2021). The data presented was factual, but was also made more meaningful by the narrative. The following is an example of these two claims working together to strengthen the messaging:

"We're keeping plastics in the system, and out of the environment, by buying recycled plastic – sometimes called post-consumer recycled plastic (PCR) [qualitative achievement]. We're ramping up how much recycled plastic we use [qualitative achievement]. Since 2018, we've increased our use of recycled plastic to around 17% of our total plastic footprint [quantitative achievement]. This puts us on track to meet our commitment of at least 25% recycled plastic by 2025 [goal]." – Company F

In addition to stated achievements, the organization shared their future goals for improving sustainable packaging outcomes. The same three sub-themes were observed (designing for sustainability, waste reduction and wellbeing and safety). Unlike the achievements theme which was evenly distributed, the future goals theme was skewed toward qualitative statements over quantitative statements. Much of the quantitative future goals were tied to the promises these organizations made when joining the Ellen McArthur New Plastics Economy Global Commitment as signatories. For example, there are statements such as "100% packaging designed to be recyclable by 2025" (Company E) across several cases. This indicates that for this data set, numerical targets are less frequently occurring than narrative about the brand's future potential. One could interpret this as a hesitation to commit firmly to future outcomes.

The highest frequency of codes by far (61) was in the design for sustainability theme, indicating that brands have room for growth when it comes to the sustainable packaging they use for their products. The waste reduction sub-theme, which included goals to improve waste collection systems, was next most frequently occurring (coded 18 times). This is in line with the lack of infrastructure barrier present in the data. The least frequently occurring sub-theme in the future goals was wellbeing and safety (coded 9 times) which focused on protecting the health and safety of stakeholders. This was also the least frequently occurring theme in achievements. The claims in this last theme were completely qualitative, with very little detail provided. The following is an example of this type of claim:

"We have two challenges to overcome to increase our usage to meet our commitment. First, sourcing the small available quantities of recycled plastic. Second, safely using recycled content in line with varying food safety regulations across the globe." – Company C

Given the prevalence of goals and achievements related to product packages and the systems that process them, it is possible that wellbeing was not seen as a part of packaging and represented in other areas of the brand owner's websites.

While reuse and refill was coded 12 times for achievements and 16 times for goals, 3 companies in the sample had no evidence of reuse/refill achievements and only 3 clearly identified goals around creating reusable or refillable options more prevalent among their brands. This is despite the fact that these organizations had a total of 39 reuse pilots running in 2021 as reported by EMF Global Commitment (The Global Commitment 2022, n.d.).

The company websites in this sample also shared the challenges and enablers of sustainable packaging. The three main challenges identified in the sample included the global scale of the packaging waste problem, the complexity of the issue given its interdisciplinary nature that requires stakeholders to work together, and finally the lack of current infrastructure to do better. On the other hand, the possible enablers to improve sustainable packaging included building circular systems for materials, educating stakeholders (including informing consumers and advocating to legislators), financial investment, and technology.

Working with partners to enable sustainable packaging was the most commonly identified enabler in this sample. This is consistent with the literature as packaging is a highly interdisciplinary field, which requires that the whole system be evaluated (Afif et al., 2021; Coelho et al., 2020). In all 8 cases, these organizations pointed to being a small part of an overall system. The narrative around their individual roles in these partnerships differed within the cases. Some organizations positioned themselves as a leader in the field, while others took on a victim position resulting from the lack of infrastructure. Table 3 provides examples of these two types of narratives. Future work will investigate further to evaluate how these narrative choices relate to how these firms take on responsibilities around production and waste.

Partnerships were also identified as commonly linking to other enablers, making them strategically the most important tactic communicated by these organizations online. For example, financial investments shared with partners:

"In 2020, our investment partner, Circulate Capital Ocean Fund, invested US$19 million in four leading companies in India that are using technology and innovation to scale and transform India's waste management and recycling value chain." – Company G

Similarly, technology and education enablers were also connected to the partnerships sub-theme.

"For instance, Mizone, China's leading vitamin water brand, has launched the world's first-ever "Carbon Smart" concept bottle, a solution developed in partnership with LanzaTech which is using cutting-edge technology to capture and convert CO2 to make PET plastic bottles." – Company B

| | |
|---|---|
| Leader | EPR, if properly designed and funded, can provide meaningful support for recycling, particularly when the right conditions are in place for a given market. [Company G] has extensive experience participating in EPR programs in different parts of the world, and we use our experience and insights to deliver constructive recommendations when such programs are being pursued or developed. – Company G |
| Victim | We can't reach our 'better plastic' goals unless there's enough high-quality recycled plastic available. There's no shortage of plastic in the system – but there are some big challenges. Turning plastic waste and pollution into usable material relies on local collection and sorting facilities. – Company H<br><br>According to the Ellen McArthur Foundation, recyclability is defined as being done in practice and at scale. Some of our Ellen McArthur Foundation plastic is recycled in practice and at scale but the majority of our plastic is "recycle ready", which could be recycled if the infrastructure existed. – Company C |

**Table 3. Communicating partnerships.**

The challenges for sustainable packaging were largely in line with current literature which identifies the interdisciplinarity of packaging (Afif et al., 2021; Ertz et al., 2017). Lack of infrastructure was the most frequently quoted challenge in the corpus, occurring 24 times, and representing just over half of all claims related to challenges. If infrastructure is poor for single-use products, the added complexity of refill and return systems is also impacted. Research shows that complex reverse logistics are a challenge for returnables (Coelho et al., 2020). A commonly identified barrier to returnable packaging to date is connected to poor cost-benefit outcomes (Afif et al., 2021). These challenges were not presented in this customer-facing source of media. To the contrary, the brands present themselves as investing in resources to advance the industry, as can be seen in this example:

"To address the issue, we are investing hundreds of millions of dollars to reimagine and redesign our packaging." – Company D

The challenge with arguments around infrastructure, scale, and interdisciplinarity is that if sustainability is everyone's responsibility, then it is equally no one's. The presence of these "it's too big for us to solve alone" narratives is that they can serve as a red herring for accountability (Buse et al., 2022). However, when balanced with the high number of partnerships around sustainable and reusable packaging in this corpus, one can be hopeful that these companies are moving in the right direction of addressing the systemic issues in packaging consumption and waste.

## Acknowledgments

The author would like to express appreciation to her thesis supervisor, Dr. Ojelanki Ngwenyama, for his ongoing support. Financial support for this research was provided by Toronto Metropolitan University.

# A software tool for manufacturing companies based on material flow cost accounting – An enabler for a resource-efficient and sustainable circulareconomy

**Magalhães Wiedmann, Caetê[a]; Hendrich, Aline[b]; Preiß Marlene[b]; Lenard, Patrick[a]; Steinert Tobias[a]; Hedemann, Jan[a]; Dos Santos, Maria[c]**

a) iPoint-systems gmbh, Reutlingen, Germany
b) Institute for Industrial Ecology, Pforzheim University, Pforzheim, Germany
c) iPoint-Austria gmbh, Vienna, Austria

**Keywords**: Material flow cost accounting (MFCA); circular economy; resource efficiency; manufacturing industry; cleaner production.

**Abstract**: Material flow cost accounting (MFCA) is a method that aims to identify inefficiencies and reduce waste in production processes by quantifying the actual costs of waste. Reducing waste contributes to a reduction of needed material, which in turn leads to a circular economy. The method, which is standardized in the ISO 14051, is currently limited as it does not support the user in finding suitable improvement measures. The goal of the study was to create methodological improvements and a digital tool that support the MFCA user in this endeavor. This was achieved by developing a prototypical expert system that supports the user in the assessment of his improvement measures. This allows companies to better determine whether it is worthwhile to implement improvement measures, taking into account various aspects of the assessment such as costs and environmental impacts.

## Introduction

There is no doubt that the urgency to act against climate change is not only as important today as it has ever been but will continue to grow. This concerns individuals and policy makers, but also different industries and individual companies. Our research offers a powerful method based on material flow cost accounting (MFCA) to make manufacturing processes more resource efficient and thus making the products more sustainable.

Material flow cost accounting (MFCA) is a method which was developed in Germany and Japan and standardized as ISO 14051 in 2011 (International Organization for Standardization 2011). The method aims to identify inefficiencies and reduce waste in production processes by quantifying the actual costs of waste. By performing a material and cost flow analysis, the method creates transparency in the companies process chain, making hidden costs in the companies visible.

The method has great potential due to the combination of ecological and economic aspects. However, it still lacks broader application in the manufacturing industry. One reason for this is the challenge of finding suitable improvement measures, and to evaluate them holistically in terms of their costs and environmental impact.

Such a holistic evaluation has been in past very difficult due to the previous approach of MFCA calculations. These were based on sequential cost calculations and made it difficult to evaluate individual improvement measures. This resulted in the need for a new algorithm that would allow a comparison of several optimized production scenarios and their potential to reduce material loss. Which enables companies to assess whether optimizations of their production processes are worthwhile in order to save material, costs and emissions.

This research is part of the "Material Based Improvement Assessment" project which aims to provide a basis for further methodical development of the MFCA method. And to develop a prototypical expert system that supports the user in the process of improvement assessment. The emphasis of this paper focuses on the development of this software tool.

## Methodology

To provide the expert system with the most comprehensive and informed decision-making basis possible, it was first necessary to create a knowledge base to integrate technical efficiency measures into the MFCA framework.

This required the identification of typical clusters of improvement measures. Therefore, a comprehensive review of 75 MFCA case studies was conducted, which encompassed consulting projects, funded initiatives, and publications.

After conducting the review, industries and process technologies were ranked based on their significance, considering several key factors such as the industry, the country, the company size, the specific improvement measure, and the reference process technology.

Based on this prioritization, expert reports were put out to tender and assigned to qualified experts in the respective technology areas. Table 1 provides an overview of the resulting 14 expert reports and their distribution among the technology fields.

**Table 1. Overview on the range of topics covered by the expert reports.**

| Technology field | Number of Reports |
|---|---|
| Plastic injection molding | 2 |
| Aluminum die casting | 2 |
| Surface treatment | 3 |
| Punching and cutting | 1 |
| Machining | 2 |
| Additive manufacturing | 1 |
| Packaging | 1 |
| MFCA International | 2 |

These reports aim to provide a clear and transferrable description of the current state of technology and typical areas for enhancing resource efficiency. And were then to be integrated into the expert system.

Theoretical and programming work was carried out to develop an innovative algorithm that enables holistic scenario comparison calculation. This algorithm was prototypically implemented in the UMBERTO modeling software and subjected to mathematical tests based on existing MFCA models to validate its feasibility.

After the algorithm calculations had been verified, workshops were held together with a multidisciplinary team. The workshops were based on the user-centered design principles (ISO Standard No. 9241-210:2019) and involved MFCA experts and software developers to design the possible user functions derived from the algorithm. The first step was to describe the initial situation and define the user's needs. Then, a possible workflow was sketched from the user's point of view and visualized using digital wireframes.

Subsequently, the results of the workshop were documented in user stories and used as requirements for the software development. The resulting software features were then iteratively implemented in prototype form and tested by MFCA users.

Seven manufacturing companies were then consulted to reproduce their manufacturing processes in digital models. To achieve this, MFCA workshops were conducted with each of the companies to outline the production flow of one of their products. Subsequently, the companies provided data on the products such as material composition and process data such as energy consumption, labor costs and material waste.

Umberto (Version 11) and the ecoinvent database (Version 3.9) (ecoinvent, n.d.) were used to create MFCA models as shown in Figure 1. The MFCA models served as a basis to finally test the algorithm and the derived features for their functionality in simulated operating environments.

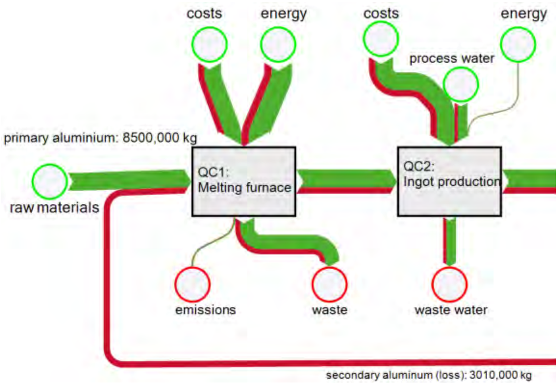

**Figure 1. Section of a simplified MFCA model in UMBERTO.**

## Conclusions

The expert system was implemented as a prototype feature in the UMBERTO software. As illustrated in figure 1. the user is supported first by visual support mechanisms to identify potential savings in the system (marked as red flows). In addition, the user is provided with a tabular summary that outlines the potential reduction scenarios, as depicted in Figure 2. The summary not only shows the mass-based material savings but also includes information on the associated cost and emissions savings.

System-wide Saving Potential

| Item | Flow (Mass) | Unit (Mass) | Monetary | Unit... | Flow (GWP) | Unit (GWP) |
|---|---|---|---|---|---|---|
| Maximum Improvement potential* | 1.919,365 | kg | 20.704,526 | EUR | 1.954,480 | kg CO2-Eq |

Single Process Saving Potential

| Item | Flow (Mass) | Unit (Mass) | Monetary | Unit... | Flow (GWP) | Unit (GWP) |
|---|---|---|---|---|---|---|
| QC3: Forming | 273,026 | kg | 719,529 | EUR | 172,709 | kg CO2-Eq |
| QC5: Rolling | 889,755 | kg | 10.029,218 | EUR | 945,678 | kg CO2-Eq |
| QC6: Cutting | 928,191 | kg | 10.726,823 | EUR | 991,836 | kg CO2-Eq |

**Figure 2. Summary of improvement potential in the expert system.**

In a next step, it was initially planned to provide a self-learning system that suggests suitable improvement measures to the users and their specific MFCA models. During the project, a concept was developed with the help of the user centered design processes. However, a software implementation could not be carried out within the scope of the project. The user is therefore redirected in the expert system to an online database with case reports from MFCA and resource efficiency projects, which can be used to collect incentives for possible improvement measures. It is also planned to integrate the technical reports resulting from the project into this database.

The expert system offers the possibility to assign the expected investment costs to different optimized production scenarios which are shown as cases in figure 3. Each case represents a scenario in which one or several improvement measures have been implemented in the model. By providing economic and environmental indicators for each case, such as ROI, discounted payback period, eco-efficiency, and $CO_2$ avoidance costs each improvement measure can be evaluated.

| Item | Potential Savin... | Unit... | Investment C... | Unit... | ROI | % | Net present val... | Unit... | Discounted pay... |
|---|---|---|---|---|---|---|---|---|---|
| Case 3 | 19.519,85 | EUR | 50.000,00 | EUR | 184,01 | % | 42.006,00 | EUR | 2,66 |
| Case 2 | 11.699,09 | EUR | 30.000,00 | EUR | 183,81 | % | 25.143,20 | EUR | 2,66 |
| Case 1 | 5.135,75 | EUR | 20.000,00 | EUR | 121,04 | % | 4.207,13 | EUR | 4,10 |

| Item | Potential Savings* | Unit (Pote... | Investment Costs | Unit... | CO2 avoida... | Unit (C... | Ec... | Unit (Eco Efficiency) |
|---|---|---|---|---|---|---|---|---|
| Case 1 | 462,64 | kg CO2-Eq | 20.000,00 | EUR | 8,65 | EUR/kg... | 0,12 | kg CO2-Eq/EUR |
| Case 2 | 1.143,26 | kg CO2-Eq | 30.000,00 | EUR | 5,25 | EUR/kg... | 0,19 | kg CO2-Eq/EUR |
| Case 3 | 1.820,95 | kg CO2-Eq | 50.000,00 | EUR | 5,49 | EUR/kg... | 0,18 | kg CO2-Eq/EUR |

**Figure 3. Summary of possible improvement measures assessment.**

This development provides a model-based decision-making framework that not only enables companies to receive insight about the current state of their production, but also offers them the new possibility to map future changes in their production as scenarios and to evaluate them holistically. This can support companies in making their production more efficient and sustainable and facilitates the holistic comparison of different design decisions regarding environmental and cost impacts already in the early stages of decision-making.

Such a tool can be used to assess the impact of conventional strategies to improve the circularity within a production, such as increasing the proportion of recycled material, introducing internal recycling loops, and increasing recycling efficiency (Kircherr J, Reike D, Hekkert M (2017). A holistic assessment of such strategies reduces the risk that decisions to improve the circular economy will ignore other issues such as increased energy consumption, costs, and greenhouse gas emissions (Kravchenko M, et al., 2020).

This is not only the basis for a multi-criteria digital assessment tool that could be extended in the future to include circular economy indicators. It is also a practical enabler for the manufacturing industry to decrease its resource demand by reducing waste and increasing its productivity, thus also contributing to a circular economy (Nishitani K, et. al. 2022).

## Acknowledgments

This project is part of the funding program: "Digitalization & Ultra Efficiency" of the Ministry for Environment, Climate and Energy Management Baden-Württemberg. Research from 01.12.2019 (funding code BWDU20108).

# Producers' consumption behaviours: Are they looking for durability in products?

**Mahajan, Deepti[a], Cooper, Tim[a], Smith, David[a], Kent, Anthony[a]**
a) Nottingham Trent University, Nottingham, UK

**Keywords**: Product information; Producers; Consumer behaviour; Consumer durables; Product lifespan.

**Abstract**: People working in an industry can be agents for developing a more circular economy if they believe in it and take decisions in their work and personal life accordingly. Managers' interpretations of quality drive their decisions on product quality, which is a prerequisite for making products last longer. They are liable to be more informed about industry-related issues than the consumers of its products. This paper enquires about the experiences and attitudes of industry managers towards product lifespans and durability, exploring whether they look for durability in their personal consumption. Semi-structured interviews were conducted with industry managers working in various departments. Thematic analysis of data was conducted using NVivo. The research found that, in general, despite their exposure and engagement with the debate on product longevity, managers did not display adherence towards sustainable consumer behaviour. When consuming products, they demonstrated low lifespan expectations and justified premature disposal.

## Introduction

The pace of progress towards creating a circular economy has been unsatisfactory and requires acceleration (European Commission 2019; Lahti et. al. 2018). Reasons could lie in the fundamental way in which businesses take decisions (Cooper 2020). Tacit assumptions and belief structures affect the judgments made by managers (McGrath 2016; Walsh 1988) and thus the outputs (Kowalski-Trakofler et al. 2003; Walsh et al. 1988). Managers interpretations of quality drive their decisions on product quality (Feigenbaum and Feigenbaum 1999) and product quality is a prerequisite for making products last longer (Seawright and Young 1996; Garvin 1984). By making products last longer, the material flow is reduced (Bakker et al. 2014); therefore, product longevity provides a route to sustainable consumption (Salvia et al. 2016).

The need to remodel markets raises some fundamental assumptions and perceptions on which decisions are made (Horlings 2015; Epstein and Buhovac 2010). Businesses entering the circular economy experience a highly uncertain environment (Lahti et. al. 2018) and therefore decision makers require a strong alignment with sustainability values (Tainter 2010; Dahl 2012) in the professional space. Decision making in a professional setting has been related to personal values and therefore personal perceptions (Rickaby et. al. 2020). Managers in industry can be the agents for incorporating a more circular economy if they believe in it and take decisions in their work and personal life accordingly. However, as decision makers in business they may have beliefs that do not allow them to take or support transformational and effective decisions (Horlings 2015). Yet, similarly, if they expect products to last only a little longer than the market average and, as a part of a team, create a product that lives or performs a little better than the market average, they may be happy and satisfied with their work (Cross and Brodt 2001), even when theoretically they understand that to ascertain product longevity requires strategies and actions beyond incremental improvements. Therefore, revisiting how managers understand quality and how they relate it to longevity may provide helpful insights regarding the preparedness of businesses in transforming consumer goods markets such that longer lasting products become a norm.

This paper enquires about the experiences and attitudes of industry managers towards product lifespans and their buying behaviour and lifespan expectations with the aim to explore whether they look for durability in their personal consumption. It also compares their expectations of product lifespans for a selection of durable products with those reported in various studies on consumer behaviour, as summarised in Montalvo et. al. (2016). The results are indicative of the preparedness of businesses to transform consumer goods markets towards increased product longevity, which was studied as a means of understanding the readiness of managers to adopt behaviour that prolongs the life of products in their personal consumption.

## Method

Semi-structured interviews were conducted with 52 managers from functions such as design, buying, manufacturing, marketing and after-sales, from three industries in the UK: clothing, household appliances and private transport. They were required to discuss their experience of durable products in general and how they judged quality in products while purchasing. Participants were asked to choose a specific type of product; most chose clothing. Thematic analysis of the data was conducted using NVivo. Recurring ideas were identified from this data and are presented in the results section below.

Participants were asked to provide an expected lifespan for a range of durable products (a piece of office wear, washing machine, bicycle, bed frame, laptop and smartphone). Average expected lifespans were calculated and compared with the results from a European study (Montalvo et. al. 2016). Participants were requested not to answer from the perspective of their potential consumer base but instead, personally as individual consumers, outside of their work and specialisation domains.

## Results

This section is divided into three parts, which addresses participant's experience of consumer durables' lifespans, their expectations and the product quality parameters in their personal consumption journeys.

The research found that managers, who make routine but critical decisions in companies, used their experience and knowledge of products in their personal buying journeys and had low expectations of products' lifespans. In general, despite their exposure and engagement with the debate on product longevity, they did not display adherence towards sustainable consumer behaviour.

### *Experience of lifespans*

While comparing their experience of products from today to when they were children or the experience of their parents, some felt that products used to last longer. Mindless and wasteful buying was also mentioned. Family upbringing, described by one participant as "*the behaviour that you inherit*", influenced consumption habits.

Not all products were equally condemned. Participants were relatively more annoyed with the lifespan of electrical goods, especially smart features, which were considered to decrease lifespan: "*an LCD screen on the washing machine… adding complexity to it… failing in five years.*" In contrast, increased reliability of vehicles was appreciated by a participant.

Reasons for lower lifespan were shared. Companies not wanting to design for longevity was cited as a reason for inadequate product lifespans. Some participants also reported discontent with the attitude of after-sales teams over returns and repair requests. Concern at product failure was reportedly not taken seriously, which was considered upsetting.

Planned obsolescence was indicated in their experience. "*I'm sure that washing machines have a 10-year switch*" and "*stop working just as the warranty fails.*" Participants did not associate lower product lifespans with the engineering expertise in companies; they reported that, technologically, products were designed to do their jobs better in terms of performance and features. Planned obsolescence was, instead, attributed as going "*against the business model.*"

Affordability and life stage were reported to limit the quality of products bought and thereby their lifespan. For instance, during student life, limited financial resources implied a need for cheaper products, whereas in later life stages price consciousness was related to buying the best value products rather than the cheapest, however, they also justified buying poor quality items if these served their requirements and budget.
Some participants acknowledged that they were not conscientious about products' lifespan

when purchasing products. Despite being aware of the longevity debate, they either did not purposely look for lifespan-related information or did not demand it, attributing this to a lack of access to easily available and visual information. During the interview some participants realised that the idea of purposely looking for lifespan-related information had not occurred to them.

Practices in contrast with sustainability-related behaviours- such as owning fewer pieces of clothing, washing clothes less frequently, using bicycles for daily commutes and replacing products only when they failed – were reported. A few participants resonated with ne who said "*I have a lot of clothes... because I work in the fashion industry.*" Another participant reported that norms such as washing an item "*because (they) have worn it once*" were prevalent. Other participants justified premature disposal using reasons: "*it doesn't look good anymore*" or "*I will get bored.*"

A relationship of product price, value, quality and branding with its lifespan was vague in its details. Participants said that they continued to believe "*quality to be less if the price is lower, even though I work in industry and know that that's not the truth.*" Quality was conveniently compromised for value, but not always due to budgetary limitations, and perceived value was prioritised over budget. Even when a participant could afford a better made product at higher price, the preference was for one that represented greater 'value for money' over one of higher quality, "*I'll buy one that's solid wood rather than something that (I) can get cheap, but (I) equally understand that I can get solid wood from IKEA and it'd be better value than maybe solid wood from an oak furniture shop.*"

Higher product price and brand identification were used to avoid poor product experiences. Price was often used as a proxy for lifespan: "*there's something linked with price in our head*"; "*depending on the price point, I think you have expectations of what you're going to get, if you're willing to pay a bit more, you're going to have a longer life.*" Branding and advertising affected the perceptions of participants. Positive brand reputation promoted a subtle belief that the product would last, although even if a product had served them well, some lass popular brands were rated "*rubbish.*" Brand was used as a proxy for quality, but brand loyalty was weak.

A need to justify expectations of a long product lifespan was reported; such expectations were compared to being a "*fetish*", "*being optimistic*" or not being "*objective*" but influenced by personal feelings and opinions. Some participants categorised themselves as fortunate to "*have the mindset of buying better quality items.*" When products failed, few considered themselves at fault for mistrusting a brand, "*but normally, I'm really annoyed at the brand that they haven't made what I thought I was buying.*"

### *Lifespan expectations*

Participants were asked to provide the expected lifespan for six products: an item of office wear such as a shirt, washing machine, bicycle, bed frame, laptop and smartphone. For products such as office wear, washing machines and bicycles, use frequency data was also collected in order to estimate the total number of times the product would be used in its expected lifespan. The frequency of use for other products was assumed to be daily (Table 1).

The average expected product lifespan of products was calculated from replies to the question: 'How long would you expect the product to last with you ideally?' These were compared with data from Montalvo et al. (2016) In each case the average lifespan in the study was greater. This may be because participants were aware of the longevity debate and therefore had greater expectations from products. Also, many managers reported buying brands and from "*higher end retailers*", which indicates they were able to afford better made products (possibly in the premium range), and therefore were likely to have higher expectations.

Use frequency data provided some behavioural insights. Many participants owned bicycles, only seven participants reported a use frequency of more than once a week; out of these, four reported daily use. On average, participants expected bicycles to last 2.6 years with daily use.

Most participants used their washing machines more than three times a week. Usage would be affected by the size of load and the frequency with which clothes are washed. On average, participants expected washing machines to last 7.5 years' worth of daily use. This may be contrasted with the claim of one company that its washing machines are tested to last an equivalent of 14 years' worth of one cycle per day (Miele 2023).

The average expected lifespan for office wear was equivalent to around six months of daily use (173 wears). Although data on ideal clothing lifespans is lacking (Laitala et al. 2018), current consumer expectations are thought to be low (Cooper et al. 2014; WRAP 2017; Sakay 2021).

Participants used language suggesting that they had high expectations of product lifespan, but this was not reflected when indicated in numbers. For instance, a garment that was described as "*really robust*" was expected to last "*a minimum of six months, if not longer.*" A participant did not want to change products "*until I need to*" but expected a jumper to last for a mere two seasons "*if it's still fashionable and not ruined.*" For a laptop, one participant said that "*given you have spent two thousand pounds, you'd get a minimum of five years, but in reality, I never get more than two.*" Expecting and buying products with short lifespan did not appear to worry participants. A lack of availability of longer lasting products and lifespan information were reasons cited for their behaviour.

Some participants who were content with product lifespans, appeared to have adjusted their expectations. They reported that consumer demand and the product were seamlessly synchronised through branding and communications, such that the markets offered what the consumer was expecting. They also used the phrase 'you get what you pay for' as a justification for not buying the cheapest products and for buying relatively expensive ones (but not luxury). "*Generally, we'll always try to buy quality so I would never go for the cheapest… so, if you pay a little bit more you do get product that will last a bit longer.*"

### *Consumer's product quality parameters*

All participants shared elements that they considered for judging the quality of a product in their purchase journeys.

Participants reported that the role of their prior experience and subject matter expertise in their purchase decision making was high. "*I make my purchasing decisions quite carefully… possibly because of the industry I'm in.*" Some judged product quality from the brand. Selection of brand also reflected their personal experience and expertise: "*the brand that fits the quality criteria I'm looking for.*" Construction or make was considered the ultimate test for quality, and 'well-made' also meant "*good finish.*" Some participants used country of origin as a surrogate to judge product quality.

Reference to price sensitivity did not mean choosing the cheapest; it hinted at value, which had to match their personal interpretations of value. Value perception was important; for instance, expensive brands were believed to be higher quality but were considered more valuable when bought in a sale or at a discount, perhaps because, though appreciated for better quality, they are normally considered over-priced.

There were parameters that were not commonly recognised as elements by which to judge quality. For instance, fit for clothing was considered an important buying criterion but participants hesitated to associate it with quality. Similarly, end use was important for items bought for occasions such as themed parties or weddings but this was not related as quality. For technology products, "*future proofing*" was valued for new purchase or upgrade.

| Participant | Office wear shirt | | | Washing machine | | | Bicycle | | | Bed frame | Laptop | Smartphone |

**LEGEND**:
Expected duration in years (D); Frequency of use ($\eta$); Number of uses in the lifespan (n)
p.w. - per week; p.m. - per month; p.y. - per year; Av. - average; exp. - expected

**NOTES**:
*Lifetime was taken based on human life expectancy in the UK, estimated as 81 years, Ref: https://www.macrotrends.net/countries/GBR/united-kingdom/life-expectancy
**For washing machines, where $\eta$ was not stated but typically described as 'very regular use', assumed to be once per day.
***For bicycles, where $\eta$ was not stated, assumed to be an average of 1-2 times per month (1 for calculations in column 10). Most participants indicated that they only cycled in summer, if at all.
$\eta$ for bedframe, laptop and smartphone: Assumed to be once per day.
- = missing data

***Table 1: Summary of participant responses***

In general, participants wanted to own products that were durable. However, ease of use, easy care and low maintenance were considered actively during decision making while durability was not; aesthetics and performance ruled their buying decisions. Participants did not compromise on appearance. Performance and features were referred to interchangeably, especially for technical products. For expensive products the key criterion for satisfaction was performance: the product must "*balance… what it is expected to do and do it well*" and "*look good.*" Participant's references to buying products "*to make myself look cool*" or because "*we want something different*" confirmed that aesthetics was considered important.

## Conclusions

This innovative study on the experiences and attitudes of industry managers towards product lifespans examined their buying behaviour and expectations in order to explore whether they look for durability in their personal consumption.

The interviews provided insights into participants' personal beliefs and practices as consumers. It was observed that certain sustainability-related behaviours - such as owning fewer pieces of clothing, washing clothes less frequently, using bicycles for daily commutes and replacing products only when the original products failed, were not common amongst them. Participants demonstrated low lifespan expectations and justified premature disposal. In summary, the interviews demonstrated that, despite engaging in the lifespan debate, their experience and knowledge was not reflected in their personal consumption styles.

The following common themes were observed:

1. Low lifespan expectations: Most participants considered themselves fortunate to have the resources to buy middle range to premium products. Despite this, they had low expectations of product lifespans. This indicates influence of marketing communications. In general, they did not demonstrate a purposeful search for longer lasting products in their purchase journey. Instead, they felt an urge to justify choices of buying expensive products as niche behaviour (Langley et. al. 2013).
2. Premature disposal: Many participants indicated that they discarded functional products and reported trading them in prematurely for new ones, for reasons such as getting bored of using them, believing that they were less efficient or no longer finding them aesthetically satisfying.
3. Dissatisfaction with planned obsolescence: Some participants argued that products broke down in the short- or mid-term because longer lifespans would not fit the business model. Technological advancements were cited as deliberate attempts by companies to make consumers feel the need to want to update their products or try new ones.
4. Price-lifespan relationship: Many participants used cues such as price, segment, marketing communications and reviews to predict a product lifespan when purchasing. Many presumed that products priced a little higher would last a little longer. Even when having to pay higher prices, participants admitted that they did not enquire about product lifespan. Brand, chosen on experience and expertise, was used as a proxy to avoid future product failures, but was also criticised.

This research confirmed findings from past studies on product lifespans (Montalvo et. al. 2016; Langley et. al. 2013), that a lack of information was not the sole or primary barrier to longer lasting products and provided supportive evidence. Participants, on account of their employment experience, did not lack awareness about the longevity debate but most indicated that they did not deliberately look for longer lifespan in products and had low lifespan expectations. Their behaviour as consumers was not very different from that reported in other consumer behaviour research. Their readiness of managers to adopt behaviours that prolongs the life of products was low. This might affect the preparedness of their businesses to transform consumer goods markets into a more circular model and highlights the need to scale up sustainability efforts in the consumer goods industry.

## Recommendations

In line with proposals made in Montalvo et al. (2016), our research indicates that support is needed for consumers and producers in decision making. As consumers, participants noted the lack of information available regarding product lifespans, because of which they inclined towards using proxies such as price, brand and their experience and industry expertise. More approachable and visible information regarding product lifespans could make a difference in the way consumers shop for durable products and re-enforces the need for expediting research to identify an appropriate product labelling system (Cooper et. al. 2014; Klepp et. al. 2020).

The idea of products lasting longer appealed to all participants. In contrast, lower lifespan expectations and the lack of actions attuned to the idea are indicative of a lack of belief in the feasibility of markets with longer lasting products. Acknowledging this conflict between their expectations and behaviour could bring their assumptions regarding product lifespan to the fore and lead them to contemplate whether their personal consumption behaviours influence their assumptions about the desires of consumers when deciding their product characteristics (Rickaby et. al. 2020).

The market response towards scaling up circular business models remains uncertain (Linder and Williander 2017) and requires strong decision making. While research on business models remains essential (Bocken et. al. 2014; Schaltegger et. al. 2016; Baden-Fuller and Morgan 2010), this research provides evidence for managers to look inwards as well. Acknowledging the above conflict in managers may help to increase the speed and effectiveness with which decisions can be implemented.

## Further research

The findings in this paper suggest areas of further research. It raises a concern about the future of longer lasting products in consumer goods markets, especially when synergies between managers' personal and professional actions, are missing. This research provides a timely reminder of the need to understand the role of cognitive dissonance in business matters related to sustainability (Telci et. al. 2011). Managers may be using their own buying behaviours and related beliefs as proxies for understanding their consumer base and making decisions in their roles through this lens. Research in consumer goods markets, comparable to construction industry research conducted by Rickaby et. al. (2020), would help to decipher linkages between beliefs in professional and personal life and thereby shape the product longevity debate amongst business people and policy makers.

## Acknowledgments

The research is a part of a PhD being undertaken at the Nottingham Trent University under the supervision of Prof. Tim Cooper, Prof. David Smith and Prof. Anthony Kent. The research is financially supported by the University Alliance DTA-Energy.

# A duty of care for sustainable products: can EU product safety legislation inspire new thinking for the circular economy?

**Eléonore Maitre-Ekern[a] and Kirsten Daae Wiig[a]**
a) Department of Private law, University of Oslo, Norway

**Keywords**: Duty of care; Producer responsibility; Product safety; Extended product lifetime; Sustainable circular economy.

**Abstract**: A sustainable Circular Economy (CE) demands drastic reduction of resource-use and waste generation to mitigate pressure on planetary boundaries and secure a place where citizens worldwide can benefit from good living conditions. One of the main means of achieving sustainable circularity is to extend products' lifetime (e.g. through design for durability and through repair and reuse). In this paper, we make the case that a duty of care for producers needs to become the core of sustainable product law. However, such a broad duty, based on the precautionary principle, whereby producers should not only strive to mitigate the impacts of their products throughout the entire life cycle is still missing. In order to understand what a true duty of care could mean in the context of an emerging EU sustainable product policy, we look to the field of product safety and to the General Product Safety Directive (GPSD) for inspiration. In this context, a 'safe' product is one that does not pose a threat or only a reduced threat, which is in accordance with the nature of its use and which is acceptable in view of maintaining a high level of protection for the health and safety of persons. In a sustainable CE, could producers be similarly required to place only 'sustainable' products on the market?

## Introduction

As the EU is developing an ever more comprehensive policy for the circular economy and increasingly regulating the (environmental) sustainability of products, businesses are feeling the pressure to re-think their product design, and sometimes also their business models. Indeed, the emergence of durability and access to repair requirements threatens the prevailing linear model that rests on the sale of new products.

The rationale for a shift in paradigm from linear to circular – and more broadly from wasteful to sustainable – is anchored in the growing understanding of the threat that the ecological crisis is posing to our societies, and the particular role that to our modes of production and consumption is playing in it (Steffen et al., 2015; Velenturf and Purnell, 2017). The impacts of the climate and biodiversity crises on businesses are mounting (Sjåfjell, 2020). In addition, the social aspects of sustainability (such as worker rights or gender equality) are also increasingly weighing in the balance (Raworth, 2012; Leah et al., 2013). To achieve the transition to a sustainable circular economy, it is not only our products that need to change, but also our understanding of what reasonable and prudent handling of products means, and of what constitutes the required level of care when it comes to placing products on the market.

One of the core principles of international environmental law, which is also at the heart of EU environmental law, is the precautionary principle. The emergence of the precautionary principle can be traced backed to the German *Vorsorgeprinzip* (Boehmer-Christiansen, 1994). *Vorsorge* means 'foresight' and conveys the idea of caring for the future (O'Riordan and Jordan, 1995). The precautionary principle – along with the less demanding prevention principle) has thus long been a central concept in areas where the risk of damage was very high and/or the occurrence of harm very dire. This is in particular the case when human health is threatened, such as the use of hazardous substances in products, and more generally where the use of products may prove harmful to individuals.

It is in the context that the first Product Safety Directive was adopted in 1992. The EU legislators aimed to strengthen the level of consumer protection in the EU by establishing general requirements for products that may not have been otherwise covered by specific legislation. The EU was also very preoccupied to ensure that disparities in national legislation would not impede trade and competition in the internal market (EU, 2021a).

The interesting feature of the EU policy on product safety – which will be presented in more details below – is that it appears to establish a general duty of care to “place safe products on the market” as well as inform consumers of the risks related to the use of their products (2001/95/EC, Article 3). Not only are they required to ‘worry’ about how their products may cause harm, but they have to take step to minimize the harm.

With its new sustainable product policy initiative, the EU appears to want to adopt a similar approach for the environmental impacts of products. ‘Making sustainable product the norm’, as the title of the chapeau communication reads, is no subtle warning to companies that the era of flooding the EU market with cheap, short-lived products is nearing an end. The proposed Ecodesign for Sustainable Products Regulation (ESPR) opens the door for all categories of products to have to abide by eco-design requirements related to durability and reparability, and several other sustainability criteria. Does this mean a duty of care to place ‘sustainable’ product is emerging? And what could be the consequences of that?

In the next section, we shortly discuss the origins and development of a duty of care in Europe (2), before diving more specifically into how this duty has been developed in the field of product safety (3). The next section investigates how a duty of care is developing in environmental product regulation, what consequences it may have and what lessons can be learned from product safety (4). The paper ends with conclusions (5).

## Origins and development of a duty of care in Europe

A “duty of care” is a legal standard, commonly associated with the question of fault-based liability, also referred to as negligence or culpa (Bussani & Sebok, 2021, p.167 and pp. 186-187). The threshold of the required due care relies on an evaluation of what an ordinary prudent and careful person in the same situation under the same circumstances could have been expected to do (Bussani & Sebok, 2021, p. 212). Thus, it usually requires a concrete overall evaluation of the specific circumstances of the case. Reflecting the duty of care´s characteristics as a legal standard that leaves room for dynamic and flexible evaluations (Pound, 1922, p.118). At the same time, there are limitations linked to the presumption of foreseeability of harm as well as a question of conduct rather than result.

Taking as the point of departure that a duty of care is a legal standard of conduct, its origin may be traced back to Roman law (Pound, 1922, p.115-116). The concept of duty of care is nevertheless not entirely coherent in a European context, despite the apparent common origin as the scope of the duty of care as a fault-based liability differs to some extent depending on the country in which it is enforced (Bussani & Sebok, 2021, p. 191-193). Regardless of the fragmentation, the main question in determining whether there has been a breach of a duty of care would relate to the required level of care acquired of the person that owes the duty of care (Bussani &Sebok, 2021, p. 190). This approach is what is constitutes a general duty of care in tort of negligence, which is non-statutory.

In English, the word ‘care’ has a dual meaning; worry and diligence. Taking care implies that one not only worries about the risk of damage, but also take step to avoid those from materializing (or at least from creating too grave harm). In other words, a duty of care is an obligation not just to show care, but also to act with caution (risk management) in a way that goes beyond a mere evaluation (risk assessment). A linguistic analysis of the duty of care thus implies an obligation that aims at prevention of the occurrence of harm. It may seem a bit counterintuitive then to talk about a duty of care in relation to liability where the evaluation assumes the very presence of damage. According to Buckland and McAir, (1965, p.363) one could rather speak of a "duty not to damage by careless conduct" in the question of guilt.

Following the preventative approach, de Sadeleer (2020, p.358) argues that the principle of precaution "transforms the duty of care into an essential element of any policy, ´a policy for action in the face of uncertainty'". Through the lens of precaution, uncertainty and doubt are made to play a significant role in considering what should be expected of a normal prudent person today (de Sadeleer, 2020, p. 348). Moreover, this approach typically justifies reversing the burden of proof, leaving it up to those undertaking potential harmful activities to demonstrate that their actions do not constitute a threat to health or the environment (de Sadeleer, 2020 p. 338). Hence, precaution can provide useful guidance on how to conduct the obligations following from the duty of care when faced with uncertainty as well as setting the required threshold of due care. On another hand, the determination of the risk threshold for applying the principle of precaution is generally considered a political matter (COM (2000) 1 final), which makes it somehow less reliable. The level of prevention as the duty of care demands will therefore depend on political choices. However, if taking a strong approach to precaution, the threshold of due care may be aligned with precaution in its strong sense, which would be to prevent the very occurrence of harm (Maitre-Ekern, 2019)

In addition, duties of care may also follow from statutory duties although these represent another category of tort than the non-statutory duty of care (Wilde, 2013). In the determination of a potential breach of such a duty it is not the "reasonable-man-standard" that applies but the threshold set out by the act in which the provision is found (Wilde, 2013 p.67). A statutory duty could therefore ensure a strong approach to precaution by enshrining such an approach by law. Moreover, statutory duties of care may give guidance on the extent of the non-statutory duty of care as well as possibly imposing a more stringent standard of care than would have been applied under negligence, or even replace the fault-based notion of harm with a stricter duty of care (Wilde, 2013, p.69-70). Thus, statutory duties can involve more predictability to its subjects. On another hand, statutory duties may limit the flexibility of a non-statutory evaluation of due care and possibly limiting the potential preventative effects if failing to adopt a high level of due care.

## A duty to place 'safe' products on the market

The General Product Safety Directive (GPSD) of 2001 (2001/95/EC) requires businesses to comply with minimum safety standards and inform consumers of any risks associated with their products (EU, 2021). The GPSD provides a generic definition of a 'safe' product. Products that are not covered by another specific rule on product safety must be safe "under normal or reasonably foreseeable conditions of use" (Article 2(b)). The GPSD specifies a safe product is that one "that does not present any risk or only the minimum risks compatible with the product's use". The safety of a product is further assessed based on its characteristics, effect on other products, presentation and other labelling signs, and the categories of consumers at risk when using the product (e.g. children and the elderly).

Product safety is, according to Marucheck et al. (2011), anchored in a broad understanding of 'duty of care', which aims to reduce the probability that the use of a product will result in negative consequences to people, such as illness, injury, death. In other words, the aim is to prevent the occurrence of a risk. The GPSD specifically refers to the notion of risk as the rationale for establishing safety requirements: "products … can pose risks for the health and safety of consumers which must be prevented" (Preamble 6). The GPSD does not, however, contains specific provisions that would define what a safe product is specifically, and for specific product groups. It relies in Member States to develop specific rules at national level (2001/95/EC, Article 3). This means that there is no harmonization of what safe means for a particular product or a category of products, and disparities can therefore arise.

Furthermore, Member States are in charge of checking the compliance of producers and distributors to place only safe products on the market (Article 6), and of adopting penalties in case of infringement (Article 7). Market surveillance is key to ensuring that legislation is applied, but there are inevitably variations between countries in the way the surveillance is taking place effectively. Thus, 'unsafe' products may end up being placed on the market and ending up in people's homes because of lacking or inadequate controls by one or another national surveillance authority. Finally, a Rapid Alert System has also been set up for national authorities of EU and EEA countries and the European Commission to exchange information on dangerous non-food products, and to ensure that these can then be traced and swiftly removed from the market. This system may counterbalance to some extent the above-mentioned deficiencies of some national authorities by allowing others to identify those unsafe products and take them off the entire EU market.

Some of those limitations are addressed in the Commission's proposal for a general product safety Regulation (GPSR, EU, 2021b), which is expected to be adopted formally in the first quarter of 2023. The duty to place safe products on the market and definition of what a safe product is remain unchanged. However, producers will now need to have a legal representative in the EU so that consumers can exercise legal remedies also when goods come from outside the EU. This requirement is likely to have a significant effect on products made outside the EU since the cost of having legal representation (and the risk of being sued) will increase substantially. Further, the surveillance obligation of Member States is strengthened from being essentially reactive to being proactive (including mandated coordinated control actions or 'sweeps'; article 30 GPSR).

## From 'safe' to 'sustainable' products?

From the perspective of product sustainability, the latest and most significant development is certainly the proposed ESPR, which shall replace the existing EU Ecodesign Directive (2009/125/EC). The ESPR is to be become the cornerstone of EU's CE policy. Indeed, its scope is significantly wider than that of the existing directive and covers almost all types of products to the exception of food, medicine, and other plant and animal-based products (EU, 2022). The ESPR also aims at regulating a much broader range of sustainability aspects (though limited to environmental ones), such as product durability, reparability and resource efficiency. Whereas energy efficiency has been the main focus of eco-design requirements so far, it will now be one amongst others whenever it will be relevant.

In many ways, the Ecodesign Directive, and to a greater extent the proposed ESPR, appear tougher than the GPSD. Ecodesign requirements – and thus in effect the definition of an energy efficient (or sustainable) product – are adopted by the European Commission through delegated acts, which means that there is only one set of rules for each product category that apply uniformly throughout the EU. The Ecodesign scheme does not, however, contain a broad obligation to place sustainable products on the market like the GPSD requires for safe products. It does not either make an express reference to the notion of 'risk' with regards to the types of negative impacts products may cause to the environment or the people (beyond health). There is, however, no doubt that a product does represent a risk towards the environment; the uncertainty regards the question of how and when that risk will occur (Maitre-Ekern, 2019, p. 101). The Ecodesign Directive, and the proposed ESPR, are less concerned about directly preventing environmental degradation than about creating an economy in which products last longer, are repaired and reuse, and materials recovered. This is the strength and originality of the scheme, but it is also its limitation: in the absence of specific rules, product design can ignore the environmental and social constraints of the real world. Thus, the extent of the sustainability of a specific product depends on the eco-design requirements adopted by the Commission. Several products that fall under the scope of the Ecodesign Directive (like smartphone), have not yet been regulated in spite of their high environmental impacts. As a result, whereas unsafe products are to be removed from the market and producers may face legal actions, the same is not true of unsustainable products. In other words, the negative environmental (and social) impacts caused by products (in terms of use of raw materials and energy, or waste generation; and effects on local population and working conditions) are *de facto* allowed unless specific rules are in place (such as ecodesign requirements).

The Ecodesign scheme is probably the best of the EU's toolbox on products and the CE – and is in many ways superior to the general product safety scheme – the lack of a general duty to place 'sustainable' product on the market may be regretted. In addition to imposing a general obligation on producers to aim for placing more sustainable products on the market even (and in particular) when they are not covered by specific ecodesign requirements, a duty of care would also serve another important purpose: establishing precaution at the core in environmental product regulation. Historically, duties of producers regarding the environmental impacts of their products have been essentially limited to waste management. The concept of 'extended producer responsibility' (EPR), which eventually became a core principle in EU waste law, requires producers to pay for waste management costs (Dalhammar, 2018). Although one of the aims of EPR policies was to provide incentives to make better products (in order to limit costs of waste management), such policies also effectively allowed producers to place whichever products they want on the market as long as they pay for end-of-life costs (Sachs, 2002). Precaution is largely ignored, and prevention is not well featured. In fact, EPR rests essentially on the polluter-pays principle, and its redistributive function (de Sadeleer, 2020 and Krämer, 2016).

The introduction of a general duty of care in (environmental) sustainable product law – or at least the recognition of such an overarching duty – could be a first step towards establishing precaution as the cornerstone of product policy. This would be significant in changing the paradigm that the linear economy rests on. From a basic right to place products on the EU, a duty of care would establish that, on the contrary, the market is closed unless those who want to enter it can prove and effectively ensure the sustainability of their products over time. The definition of what 'sustainable' means in this context is no simple task and would need to evolve over time as scientific knowledge and techniques develop, but broad policy documents, such as the EU Green Deal (EU, 2019), CE Action Plan (EU, 2020) and 8th Environment Action Programme (Decision (EU) 2022/591) could serve to form the basis of a common understanding. Moreover, the sustainability of products should comprise but not be limited to product characteristics (such as durability and reparability in line with the ecodesign scheme). Equally important are the service and infrastructure that allow that the life of sustainably designed products is effectively extended. Producers should thus have to plan for the entire life cycle of their products before placing them on the market, including for example considerations of who will conduct repair and where, and what structures are in place to ensure collection and reuse.

As put forward by Maitre-Ekern (2021), a sustainable product policy needs to establish a producer responsibility principle in line with the original idea of EPR developed by Lindhqvist and Lindgren (1990). Producer responsibility should not be extended only to end-of-life, but on the contrary, relate to the entire product's life cycle. This requires planning for longevity, circularity and after life already at the stage of the conception of the product, and at least before placing it on the market. In order to differentiate from EPR however, which is by now a well-established waste law principle, the alternative denomination of 'pre-market producer responsibility', based on a duty of care, is put forward to refer to this concept in an emerging sustainable product law (Maitre-Ekern, 2021).

## Conclusions

In this paper, we discussed the concept of duty of care, and its link to an important principle of environmental law: the precautionary principle. Precaution appears to be at the heart of product safety legislation and its duty for producers to place only 'safe' products on the market. In spite of being more robust and fit-for-purpose, neither the Ecodesign Directive nor the proposed ESPR contain such a duty to place 'sustainable' products on the market. The absence of such a duty of care was deplored by the authors of this paper firstly because it means that, in the absence of (sufficient) ecodesign requirements, producers have no obligation to strive to make their products (more) sustainable. Secondly, a duty of care would anchor precaution at the center of sustainable product legislation, and contribute to changing paradigm from a general right to place products on the market, to a privilege that comes under strict conditions. Such a duty of care for product sustainability would also be in line with the original idea of extended producer responsibility, and the proposed alternative wording of 'pre-market producer responsibility'.

# Studying clothing consumption volumes through wardrobe studies: a methodological reflection

**Keywords**: Methods, Wardrobe studies, Clothing use, Clothing consumption, Clothing volumes.

**Abstract**: This paper introduces the relevance of volume-centric research in studies of clothing use. The global production of garments has grown dramatically in recent decades, bringing along significant environmental challenges. However, knowledge is lacking about why people deal with clothing quantities in such varied ways, and what leads some of them to overconsumption. A review of wardrobe research methods shows that there are various approaches to studying garments going in, around, and out of wardrobes. Gathering qualitative insights about specific garments, such as favorite garments, has been quite common. However, in order to advance knowledge about clothing consumption volumes, it is important to look at the wardrobe as a whole and include quantitative aspects. This paper reflects on what approaches and techniques can be used to that end. The reflections are combined with lessons learned from a pilot wardrobe study conducted in Uruguay, Portugal and Norway in 2022 with 20 respondents, concluding with recommendations for volume-centric methods in future wardrobe studies. Rigorous accounts of all garments owned should be combined with registration of items going in and out of the wardrobe over time in order to link accumulation to production and waste volumes. Methods connecting garment quantities with practices of daily use are particularly valuable. One example that has proven successful is piling exercises, a technique where participants are invited to categorize garments in groups according to specific criteria.

## Introduction

Growing clothing production volumes are increasingly recognised as the core problem of the apparel sector's environmental impact. Global retail volume is estimated to have doubled during the first 15 years of this century (Euromonitor in Ellen MacArthur Foundation, 2017). Moreover, production concentrates most of clothing lifecycle impacts when a variety of garments are considered (Roos et al., 2015). More garments produced lead to lower clothing utilization and to more textiles ending up in landfills (Niinimäki et al., 2020). Therefore, understanding how consumption practices drive and change as a result of growing volumes is a condition to develop strategies that counter current developments.

Wardrobe studies, understood as methods that "look at the relationship between the individual item of clothing and the larger material totalities" (Klepp & Bjerck, 2014), are common in studying clothing consumption practices including acquisition, use, maintenance, and disposal (See also Fletcher & Klepp, 2017; Guy et al., 2001). However, only a few of previously conducted wardrobe studies use methods that prioritize clothing volumes or quantities. Qualitative studies focusing on favorite garments, for instance, predominate. Studies of unused and forgotten garments, on the other hand, are rare and much needed to grasp common practices in consumerist societies such as material accumulation. Since the various garments in the same wardrobe are known to behave differently in terms of durability, use frequency, and maintenance, an understanding of the dynamics of the wardrobe as a whole, including data on quantities, is central to enable reductions in consumption volumes.

Therefore, this paper calls for a volume-centric approach in wardrobe studies; namely, methods for field research in clothing consumption that focus on quantities. In order to advance such an approach, the next section draws on a semi-systematic scoping review of publications that have employed wardrobe studies. The review is complemented with lessons from a wardrobe pilot study conducted by us, the authors of this paper, in Uruguay, Portugal and Norway in 2022. The discussion in the last section combines insights from the review and the pilots to deliver recommendations for future volumes-centric research in wardrobe studies.

## Literature review

The search was conducted with terms "wardrobe studies", "wardrobe interview" and "wardrobe audit" in the title, abstract, or full text, through the databases of Scopus, Web of Science, and Google Scholar, and it focused on English language publications. This search resulted in 333 publications after duplicates were removed. In the following step, we selected publications reporting on empirical research about everyday clothing practices only, and excluded non-peer reviewed reports and master theses.This gave 105 publications that are relevant for this methodological reflection. These included, for instance, researchers visiting participants at home and discussing specific clothes with them, self-audits where participants document a section of their wardrobe through online forms, or clothing diaries filled by participants including photographs. Other studies were considered irrelevant. For instance, historical research about the wardrobe of important characters from the past or studies about personal image consultancy methods.

We found that the term "wardrobe studies" is used to refer to a range of methods. "Wardrobe interviews" tend to have a qualitative emphasis and focus on a selection of garments. Lastly, "wardrobe audits" focus on quantities and can be based on parts or the whole wardrobe. These meanings largely coincide with those recommended by Fletcher and Klepp (2017, p. 168) in their attempts to promote a shared language in the field.

In any case, a mixed methods approach is most common, as is studying a section of the wardrobe only. The academic fields represented vary from design and fashion studies to consumption studies. If we look at development in time, the use of wardrobe studies started to increase considerably in 2013 and there were only 5 studies published before that year. Since 2019, more studies have focused on sustainability in relation to clothing practices, as noted from the conferences or journals where they are published.

After reading all publications with a focus on methods, we selected the studies that counted all the garments in the wardrobe, considering that a whole wardrobe and a quantitative approach are central conditions for volume centric studies in wardrobe research. Table 1 shows the results of this process, leading to 8 studies reported in 12 publications.

The table shows that women are overrepresented in wardrobe studies. Three of the eight studies include women only, and in the other five women are a majority, reaching up to 85% of respondents. Some studies mention difficulty in recruiting male respondents for wardrobe research. The Global North and the UK specifically are overrepresented too, although this may be a result of the focus of the review on English language publications.

All studies show a remarkable variety in the quantity of garments owned by respondents. This finding, we note, highlights the relevance of this kind of research to understand what leads people to manage their clothing in such different ways. The fact that all these studies combine a whole wardrobe quantitative audit with qualitative insights from use is a promising feature in enhancing this understanding.

Not all studies provide details of the methods, but using a template form divided by garment type seems common in the wardrobe audits. Visiting participants at home to guide the counting process costs much time and therefore resources, explaining why only three from the eight studies use such an approach, and the relatively small number of respondents included in them. On the other hand, it improves the reliability of results and ensures that all respondents follow similar criteria, such as counting off season clothes stored somewhere else, or not. Moreover, researchers participating in the counting process can relate quantities to other aspects, such as the kind of clothing owned and how it is stored, providing opportunities to complement audit results with qualitative data in order to explain variety in clothing volumes decisions.

| Publication | Aim | Methods | Results | Sample | Country |
|---|---|---|---|---|---|
| Dukes (2019) | Identify unsustainable shopping patterns | • Self-audit<br>• Reporting satisfaction (or not) with the quantity owned<br>• 12 week shopping diary | • 84-313 garments<br>• Respondents did not aim for long-term use, choosing low cost garments<br>• Versatility was common for favorite garments | Six women who purchase clothing frequently | UK |
| Fletcher (2018) | Mapping the clothing activity in the town of Macclesfield | • Audit including tools and materials used for care and maintenance with researchers<br>• Estimation of garments owned by participants vs audit results. | • 224, 245 and 126 garments respectively<br>• Specific insights for each wardrobe: higher number of items for upper body vs lower body, seasonal storage, etc. | One young woman, one middle-aged woman, one elderly man | UK |
| Hackney et al. (2021); Willett et al. (2022) | Behavior change in fashion and textile practices through interventions | • Self-estimation vs self-audit<br>• Interview | • 33-340 garments<br>• wardrobe audits are efficient as research interventions | Nine women | UK |
| Klepp et al. (2019); Laitala and Klepp (2020) | Investigate the wardrobe content in five countries with large clothing markets | • Online survey, self-audit in specific categories<br>• Details about clothing lifespan, active use, occasions, material and laundering collected for some items | • 35-663 garments<br>• Consumers with large wardrobes use their clothes longer<br>• Garments in small wardrobes are used more | 1111 women and men aged 18-64 | China, Germany, Japan, UK,USA |
| Maldini (2019); Maldini et al. (2019) | Understand clothing demand in ready-made and personalized garments | • Audit with researcher<br>• Registration of garments acquired and discarded (six months)<br>• Exercises piling garments according to age and use frequency | • Approximately 70-650 garments<br>• No significant relation between personalisation and demand<br>• Insights about the dynamics of the wardrobe over time | 24 women, 16 men, aged 22-71 | Netherlands |
| Rhee and Johnson (2019) | Experiential learning activity | • Self-audit<br>• Clothing diet: wearing six clothing items for 30 days | • 38-500 garments<br>• Successful awareness raising about wardrobe size<br>• Limited accuracy of self-audits: 26 participants stopped counting | 42 fashion students aged 18-29, 85% women. | USA |

| | | | | | |
|---|---|---|---|---|---|
| de Wagenaar et al. (2022) | Explore wardrobes to develop reuse interventions | • Self-reported survey through an online course | • 30-713 garments<br>• Respondents had most of upper wear items and footwear<br>• 25% of items in the wardrobe were unused | 520 respondents, 78% women, 16% men. Aged 18-51+ | Half from Europe, half from all other continents |
| Woodward (2007); Woodward and Greasley (2017) | Understand everyday consumption practices through wardrobes | • In-depth ethnography over 15 months<br>• Mixed methods: object interviews, wardrobe audits, photography, clothing diaries and participant observation | • 35-182 garments<br>• Older women with higher incomes and more space had more clothes (accumulation)<br>• Central to clothing choices is the dynamic between the clothing worn oftentimes and rarely | 27 women | UK |

**Table 1. Studies including a quantitative report of whole wardrobes.**

Five of the eight studies in the table rely on self-reported data, and Laitala and Klepp (2020) and de Wagenaar et al. (2022) are able to include a high number of participants located across the globe through online surveys. But some acknowledge the limitations of data reliability. For instance Rhee and Johnson (2019) and Hackney et al. (2021) interviewed participants after self-audits, noting that some stopped counting part way, as the high number of clothing felt overwhelming. The limitation of self-reporting may increase if respondents are asked to estimate and count only if possible, as it is the case in online surveys.

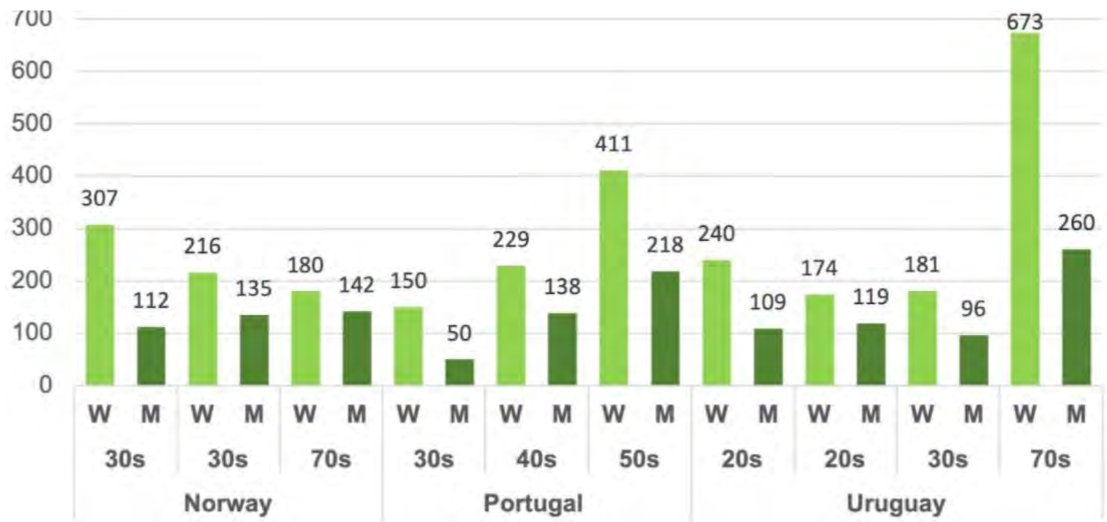

**Figure 1. Number of garments owned by respondents in our pilots excluding footwear, accessories such as hats and scarves, underwear, and socks.**

## Pilots

In 2022, we conducted a pilot study to test wardrobe methods that could help us understand clothing choices for different occasions, and their relation to consumption volumes. One of the hypotheses underlying this study was that occasions understood as everyday activities demands specific outfits. In addition, there is also a social expectation to vary between outfits for the same occasions. Combined, these characteristics of clothing consumption contribute to high numbers of garments owned.

The pilot was conducted in three countries simultaneously. We recruited participants in pairs, who lived in the same household and identified themselves as a woman and a man respectively. This choice was based on the recruitment of people that were subject to different social expectations associated with gender and dress, while they participated in similar occasions, understood as any activity performed in daily life, such as sleeping, going for a walk, or working from home. Moreover, recruiting in pairs of different genders helped us to include men in the study, with women often taking a linking role. There were 20 participants; three pairs in their thirties and seventies in Norway, three pairs in their thirties, forties and fifties in Portugal, and four pairs in their twenties, thirties and sixties in Uruguay.

The first visit included a whole wardrobe audit (see results in fig. 1), an interview, and an exercise where respondents piled and counted garments according to their suitability for different occasions (figs. 2-3). The piles were documented in a blank form, where respondents self-identified the occasions to be included. Respondents were then invited to submit photographs of their outfits when doing shared activities through an app, and to indicate the occasion of the picture. We named this assignment the “selfie method” (see fig. 4) and asked respondents to send a minimum of 10 pictures in a period of one to two months. During the final interview, some clothing choices documented in photographs were discussed.

**Figure 2. A participant going through the piling exercise.**

**Figure 3. Piles of garments divided by occasions by a participant.**

**Figure 4. Respondents reporting an activity together.**

## Discussion

Reflecting on what approaches and techniques can provide insights on clothing consumption volumes, we note that although all studies in Table 1 include an account of the whole wardrobe, methodological differences and unclarity in the process prevent comparative geographical or historical analysis. For instance some studies include underwear, accessories, and footwear, and others not. Some studies include clothing owned by respondents but stored outside their home, others not, and the clothing types in the forms are not aligned. Hackney et al. (2021) note the difference in the number of garments their participants owned compared to Woodward's (2007) and suggest this may show evidence of increasing clothing consumption linked to fast fashion. However, the small number of respondents and the methodological variety mentioned above often prevent this kind of comparisons. Standardizing the research design of wardrobe audits would enable much needed comparative research. Moreover, aligning methods and incorporating learnings from in-depth fieldwork into self-reported surveys (and vice versa) would help in building a body of knowledge that is at the same time accurate, representative, and feasible.

One lesson learned from our pilots was the importance of combining a whole wardrobe quantitative account with reports of wardrobe movements over time. This is because the number of garments owned does not necessarily correlate with the pace of inflow (clothing coming into the wardrobe) and outflow (clothing going out of the wardrobe), which are central indicators of clothing consumption's environmental impact (Klepp et al., 2019). Understanding the relationship between both is key.

Another important consideration in the research design is the relation between wardrobe volume and practices of daily use. In the pilots, the selfie method gave us data about everyday dressing decisions, but the study was not designed in a way that we could use this data to understand volumes. Altogether, these two limitations led to a redesign in the final study, where we substituted the "selfie method" for a documentation of wardrobe movements, adding photographs of the items to the method used by Maldini et al. (2019). In this decision, we gained insight about the dynamics of consumption over time, but we lost detailed data about daily use. Connecting daily clothing decisions with volumes, we note, keeps being a challenge in the field. Two of the reviewed studies have used diaries to complement the other methods in connection to wardrobe content, which gives data on certain clothing practices, such as acquisition, and how this relates to the garments already owned (Dukes, 2019; Woodward, 2007).

Asking respondents to classify and count garments in groups, for instance by piling them, has been useful in connecting everyday practices and quantities. This approach is relatively time efficient and can deliver valuable insights. Maldini et al. (2019) found that personalized garments are not used more often or longer than ready made garments through piling. The piling exercise in our pilot indicated that big wardrobes are not related to the specificity and variety of occasions considered by their users. Respondents identifying many different occasions in their wardrobe did not necessarily own more garments, partly questioning the hypotheses motivating the study.

It also showed that the difference in quantity of clothing owned by participants self-identified as men and women (women in all pairs owned more), was bigger for "everyday" and "dressed up" occasions than for other occasions like leisure and sports. Compared to gathering user data in real time such as in the selfie method, the disadvantage of piling is the self-reported nature of the piles gathered at a specific moment in time. However, we believe that this approach can be helpful in answering a variety of research questions that connect clothing everyday use practices to consumption volumes.

To conclude, we hope that the reflections gathered here will be of help to place a stronger and more productive focus on consumption volumes in future wardrobe studies, and to allow for a better understanding of the challenges and opportunities in tackling overconsumption and overproduction.

## Acknowledgments

The authors are grateful of the support from the Research Council of Norway through funding of the project CHANGE, as well as SIFO/OsloMet. We would also like to thank the participants of the pilot studies.

# Ecodesign considerations to promote the circularity of plastics from electronics, vehicles, and construction and demolition

**Tatu Marttila[a], Malin zu Castell-Rüdenhausen[b], Hannah Scoones[a]**
a) Aalto University, Department of Design, Finland
b) VTT Technical Research Centre of Finland Ltd, Finland

**Keywords**: Plastic recycling; Hazardous plastics; Circular plastics; Circularity; Ecodesign.

**Abstract**: Plastic is one of the most ubiquitous materials used in products. However, the way we currently produce, utilise, and dispose plastic is often unsustainable and inefficient. To improve the circularity of hazardous plastics, the NONTOX EU Horizon 2020 project (2019–2022) focused on plastics recycling in electronics, vehicles, and construction and demolition sector. To expand the understanding on ecodesign considerations to support plastic circularity in the focus sectors, several workshops were organised with stakeholders, and the resulting findings were further assessed in in-depth interviews with selected experts with specific roles along the plastics value-chain. This paper studies the ecodesign guidelines, and develops them further to support the transformation in how we utilise plastics in production and consumption. To promote the targets of EU circular plastics strategy, general ecodesign recommendations were gathered for hazardous plastics, and more detailed considerations were produced in regard to specific life-cycle phases. Lastly, a website was produced to disseminate the recommendations.

## Introduction

Plastic is one of the most ubiquitous materials used in products. However, the way we currently produce, utilise, and dispose of plastic is often unsustainable and inefficient. Despite its potential to be recycled and reused, plastic accumulates in the environment and in landfill (Veidis et al., 2022), and the burning of plastic waste as well as production of virgin plastics furthers carbon outset and climate change (see e.g., Chandegera et al., 2015).

The EU promotes plastics circularity specifically in its new *Circular Economy Action plan* (EC, 2020a), and *European Strategy for Plastics in a Circular Economy* (EC, 2018a) strongly promotes the reuse and recycling of end-of-life plastics. However, in Europe in several product categories the recycling rates are still low, with less than 30% of overall plastics being recycled (EC, 2020b), and the demand for recycled plastics remains small (around 6 % of demand; EC, 2018a). Furthermore, the application of recycled plastics remains often limited to low-value or niche applications. Due to limited design knowledge, lack of high quality or availability of recycled feedstock, sometimes conflicted consumer views, and poor end-of-life management and inefficient recycling technologies, there remains several barriers to the higher uptake of recycled content.

Ecodesign is an approach to design and engineering that originates from early discussions on sustainability of production in the 90s (Brezet & van Hemel, 1997). It focuses on improvements to design and manufacturing in different phases of product life, ranging from material selection to production, use, and to end-of-life. To improve the circularity of hazardous plastics, this paper studies the ecodesign guidelines in the context of circular plastics in the electronics, vehicles, and construction and demolition sectors, and develops them further to support the transformation in how we utilise plastics in production and consumption.

The NONTOX EU Horizon 2020 project (2019–2022) focused on the recycling processes and technologies to improve the recycling of plastic waste generated from Waste Electrical and Electronics Equipment (WEEE), End-of-Life Vehicles (ELV) and Construction and Demolition Waste (C&DW). As a part of the project, existing ecodesign guidelines for circular plastics were revisited and revised.

To expand understanding on the ecodesign considerations to support plastic circularity in the focus sectors, four workshops were organised with various stakeholders, and the resulting findings were further assessed in nine in-depth interviews with selected experts with specific roles along the plastics value-chain.

**Consequently, this article focuses on the following inquiries:**

- *What are the important ecodesign considerations to improve circularity of plastics?*
- *What are the specific considerations to improve plastics recycling in the electronics, vehicles, and construction and demolition sectors?*

## Context and background

### *Plastics circularity in the EU*

According to the European strategy for plastics in a circular economy, the way plastics are currently utilised "fails to capture the economic benefits of a more 'circular' approach and harms the environment." (EC, 2018b). The European Union has released an ambitious policy against single-use plastics, and to improve the recycling of plastic packaging,[1] and the need to improve recycling of plastics has been increasingly acknowledged amongst researchers, policymakers, and industry. However, plastics recycling remains underdeveloped in several sectors of production. Additional important areas of consideration also include the promotion of the use of recycled plastics in further applications, the development of closed-loop product-systems, as well as the overall extension of product and material longevity.

In approaching the role of plastics in circular economy, a report by The European Environmental Citizens' Organisation for Standardisation ECOS (2019) lists four main recommendations to promote sustainability of plastics in a circular economy:

- Design products and systems for longer lifetimes
- Make products easier to recycle
- Close the loop through recycled content
- Focus on chemicals for circular products and materials

There remains room for development in improving recycling of plastics especially in relation to more challenging plastic waste streams such as in electronic waste, end-of-life vehicles, and other specific waste streams.

### *Ecodesign for hazardous plastics*

Ecodesign considerations are focused on life cycle approach. The international standard ISO 14006 defines ecodesign as a process of "[i]ntegrating environmental aspects into product design and development with the aim of reducing adverse environmental impacts over the life time of the product" (ISO, 2011). In a simplification, ecodesign refers to those design strategies and choices (see Table 1), that are taken in the product development phase, but affect the overall life cycle of the product.

| Life cycle stage | Description | Ecodesign strategy |
|---|---|---|
| Extraction | Raw material sourcing and production | Design for low impact materials and dematerialisation |
| Manufacturing | Primary and secondary etc. production processes | Design for low impact production (also social considerations) |
| Distribution | Logistics and distribution from production to sales | Design for low impact logistics |
| Use | Impacts caused by energy use and consumables during use phase | Design for extended product/material life |
| End-of-life | Logistics and processes for end-of-life product and material management | Design for recycling |

**Table 1. Life cycle stages and the general ecodesign strategies.**

### *Focus waste streams*

In the NONTOX project, the focus is on plastic generated from Waste Electrical and Electronics Equipment (WEEE), End-of-Life Vehicles (ELV) and Construction and Demolition Waste (C&DW). According to the

[1] https://www.europarl.europa.eu/news/en/press-room/20190321IPR32111/parliament-seals-ban-on-throwaway-plastics-by-2021

EU extended producer responsibility policy, the producers are responsible of the management of WEEE and ELV through producer responsibility organisations (PROs). C&DW stream is governed by waste directives, among other frameworks (zu Castell-Rudenhausen, et al. 2022).
Electronic waste (WEEE) includes a heterogeneous mix of polymers and additives, combined with metal and electric components. Currently, the flame-retardant containing casings are removed in manual dismantling and sent for energy recovery and destruction of the flame retardants (Kaartinen et al., 2020).

In End-of-Life Vehicles (ELV), plastics comprise over 15% of the ELV waste (Frost & Sullivan, 2021). After removing reusable and valuable components, the remaining waste is commonly treated together with large WEEE, and fractions from the industry and construction and demolition activities (Cardamone et al., 2022).

Construction waste is a heterogeneous mix of various materials, with minerals as the main component (90%) and very little plastics (>1%). The waste stream is, however, the largest in Europe (Eurostat, 2020). Plastic waste in C&DW comprises of plastic products and components, but also of packaging waste.

## Case and data

To assess the ecodesign considerations in relation to the focus waste streams, four workshops were organised with various stakeholders between 2019–2021, and the resulting findings were further assessed in nine in-depth interviews with selected experts with specific roles along the value-chain (see Tables 2 & 3).

| Date | Workshop title | Focus topics; participants |
|---|---|---|
| 4.6.2020 | Eco-design guidelines workshop #1 | Internal for project partners (n=16) |
| 15.6.2021 | Advisory board meeting workshop | Focus on advisory board (n=10) |
| 27.11.2021 | Eco-design guidelines workshop #2 | Extended project network (n=20) |
| 15.12.2021 | Eco-design, recycling, and improved circularity | Extended project network (n=15) |

**Table 2. Workshop activity in 2019–2021.**

The workshop activities produced a basic overview on the value chain for circular plastics, and consequently the nine semi-structured expert interviews were conducted to further assess challenges in relation to specific phases along the value chain (see also zu Castell-Rüdenhausen & Marttila, 2023). The interviewees represented targeted sectors (WEEE, ELV, C&DW), as well as the various value chain actors, selected within project affiliate networks. The interviews used a structured outline that was distributed prior to the interviews together with complementary materials on the policy landscape in the EU. The interviews lasted between 1,5–2 hours, enabling in-depth conversation of all topics addressed. All interviews were recorded and transcribed. The interviews assessed hinders regarding the scale-up of circular plastics with solutions for tackling these, as well as on possible ecodesign considerations and opportunities.

| Date | Role and focus |
|---|---|
| 27.5.2021 | PRO: collection of ELV |
| 31.5.2021 | Converter: use of recycled plastics |
| 31.5.2021 | PRO: collection of WEEE |
| 4.6.2021 | PRO: design for recycling, WEEE |
| 4.6.2021 | Converter: use of recycled plastics |
| 18.6.2021 | Converter: use of recycled plastics |
| 21.6.2021 | Recycler: management of WEEE stream & ELV more recently |
| 20.8.2021 | Recycler: management of C&DW stream |

**Table 3. Expert interviews in 2021.**

## Analysis

In approaching plastics recycling and ecodesign, feedstock related considerations are often important. The first stage in the value chain can be divided into the recycling industry and converters and brand owners. Through the PRO scheme, a special focus is required on take back systems and pre-treatment processes. General barriers include the economic challenges for collection, supply side issues for production, but also consumer views, information, and lack of sustainably oriented design choices (see Table 4).

Specific challenges and opportunities were assessed also separately in relation to each focus waste stream. Opportunities for action and potential best practice differ from one focus stream to another, and are also based on the value chain phase (see Figure 1). Supportive examples are also presented based on prototyping activities for feedstock valorisation in the NONTOX project. A main point in prototyping was in promoting non-hazardous additives and minimising the use of hazardous ones, promoting closed-loop solutions, and revaluating waste handling schemes that could cause crossed contamination.

*Promoting plastics circularity in Waste of Electronic and Electric Equipment (WEEE)*
In plastic waste from electronics, the main challenge is the heterogeneous composition of polymers and colors as well as the potential additives (e.g. BFRs). Product design rarely supports the dismantling and separation of materials. Consumer views could pose recycled plastic as inferior. Furthermore, the recycled plastic still lacks approval for food-related products (EFSA approval). Consequenlty, in WEEE, specific emphases for ecodesign actions promoting circular plastics can be:

| Value chain phase | Challenges to plastics circularity |
|---|---|
| Plastic feedstock production | • *Mixed information on benefits of recycled plastics;*<br>• *Lack of policy push to increase recycled materials' use*<br>• *Lack of use/availability of recyclates as materials*<br>• *Plastic feedstock: Supply side is not consistent* |
| Product manufacturing (converters; OEMs) | • *Lack in offering recycled material choices for production*<br>• *Lack in willingness to utlilise recyclates* |
| Product manufacturing (brand owners) | • *Use of multimaterials / use of composites*<br>• *Introduction of materials not applicable to existing recycling*<br>• *Lack of market demand for recycled grades (of plastic)*<br>• *Lack of incentive to improve recyclability* |
| End-market consumption | • *Lack of incentives (for recycling instead of other end-of-life scenarios)*<br>• *Consumer communication: How to make it visible?*<br>• *Perceived low quality of recyclates*<br>• *Extend products' lifetime (in use phase)* |
| Post-consumer collection | • *Products not designed easily compatible with recycling systems*<br>• *Current regulation not followed*<br>• *PROs lack incentives for advanced processing* |
| Material sorting, pre-treatment | • *Products not designed for recyclability*<br>• *Discrete and mixed collection (management of waste/feedstock flows)*<br>• *Reality of processing if often simply shredding...*<br>• *Not creating new blends of (plastic waste) feedstocks* |
| Material recycling | • *Legacy of brominated flame retardants (BFRs) in various waste streams*<br>• *Regulation on BFR limits* |

**Table 4. Value-chain phases, challenges, and opportunities for circular plastics.**

- Utilise recycled feedstocks for non-essential components, and easily recyclable plastic feedstocks.
- Improve product design so that components and materials are easily separated and sorted to support recycling and reuse.
- Extend product life-time and repairability, upgradeability, and modular reusability.
- Improve separation and recycling systems.

*Promoting plastics circularity in End-of-life Vehicles (ELV)*
A challenge in plastics recycling in ELV is that valuable parts are removed before recycling, and the resulting waste stream is often

heterogeneous, difficult to process, and of low value. For the ELV, specific emphases for ecodesign actions promoting circular plastics can be:

- Utilise easily recyclable plastic feedstocks and modular design to support recycling and reuse.
- Improve take back, separation and recycling systems.
- Increase access to information on composition of plastics in car industry.

*Promoting plastics circularity in Construction and Demolition Waste (C&DW)*

Lasty, the challenge in plastics recycling in C&DW is on the low plastic content, and that the waste stream is often poorly separated and heterogeneous and of low value. In C&DW, specific emphases in ecodesign action for circular plastics can be:

- Utilise recycled and easily recyclable plastic feedstocks in construction products and packaging.
- Improve take back, separation and recycling systems in construction sector.
- Increase access to information on composition of plastics in construction industry.

*Ecodesign considerations for circular plastics*

In WEEE and ELV waste, more advanced recycling methods could be utilised if a sufficient level of homogeneity of the feedstock is achieved, and there is also a lot of potential for recyclate use. PROs are in the key position in the process but are often not properly incentiviced. Closed-loop product systems could be especially feasible in ELV and in C&DW. Furthermore, in C&DW improving collection remains a core area of development. The overall ecodesign considerations especially in relation to WEEE, ELV, and C&DW, can be summarised as four general recommendations:

- **Design for recycling:** Using recyclable materials that are easily separated and comply with recycling systems; taking into account the safety aspects of chemical additives.
- **Design for dematerialisation:** Designing with less materials and processes, or those with less impact; promoting the use of recycled materials.
- **Design for reuse and refurbishment:** Supporting repairability and modular design; taking into account user safety.
- **Design for end-of-life:** Using modular design and easily detachable material components; Not designing products, but product systems with take-back mechanisms.

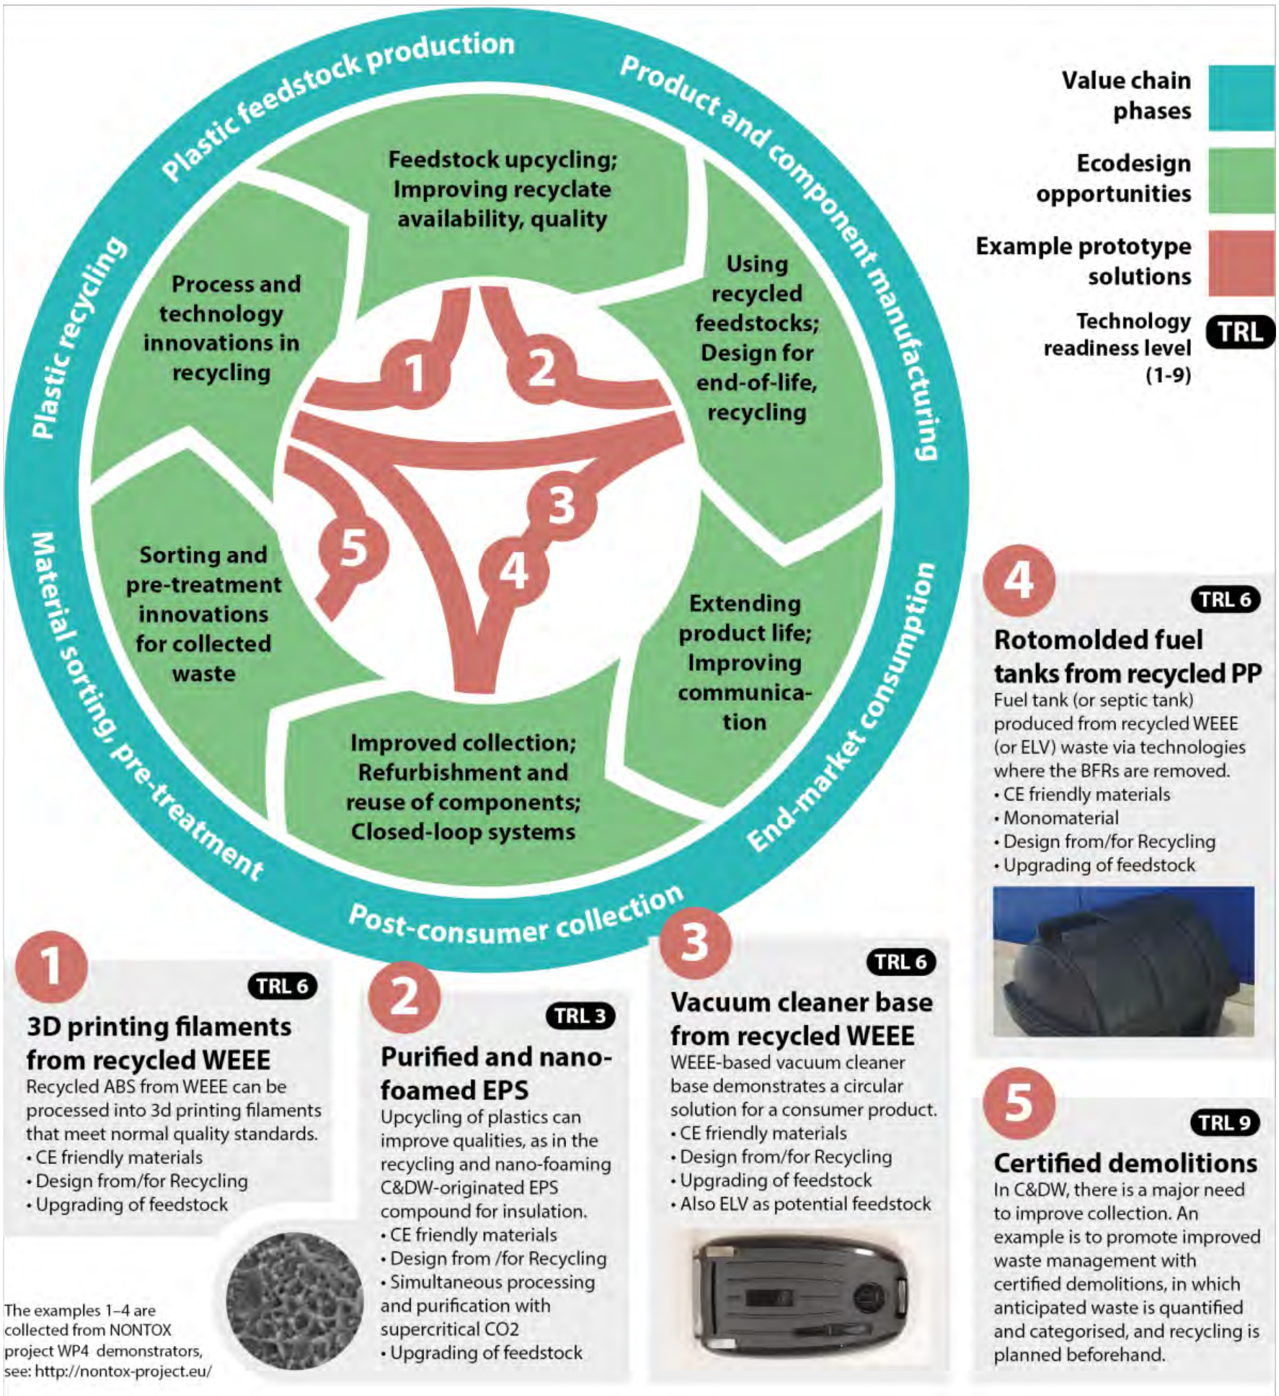

**Figure 1. Value chain phases and potential ecodesign actions, with example prototypes from the NONTOX project (see more information on valorisation prototypes in Pelto, et al. 2023).**

## Discussion

Promoting plastics circularity calls for systemic improvements to interaction between several actors. The revised ecodesign considerations for circular plastics (see Table 5) connect strongly to producers and designers, with considerations for recyclate use and end-of-life. Plastic converters have a key position in servicing various product manufacturers to create the needed components and products. Original Equipment Manufacturers (OEMs) play a crucial role in a circular plastic economy in developing demand for more advanced recycling processes. However, the pressure from consumer side focuses on brand owners that have more visibility in the markets.

Product manufacturers and brand owners have the main responsibility to make decisions about ecodesign. However, producers need to ensure their designers have access to the most recent information, and that their organisational structure supports the related design decisions. Product manufacturers are organizing EPR schemes (in WEEE, ELV), and PROs together with municipal waste collectors are in the key position to improve the management and quality of waste feed-stocks available to the recycling sector.

Recyclers are already improving technologies for more advanced recycling. Recycling of plastics in WEEE, ELV, and C&DW call for not only improved collection and sorting, but also new economically feasible technologies to manage and refine the impurities in the feedstock. Improving the technological knowledge among recyclers to also include emerging recycling technologies (such as chemical recycling) would enable more efficient recycling and safe removal of legacy substances.

The EU ecodesign directive complemented by energy labelling rules is one of the main mechanisms to push producers to improve product sustainability and to guide consumer action, primarily applying only to energy-related products (EC, 2019). In the future, ecolabelling could be developed to include the material footprint and information on recycled content, and expanded to new product domains (ECOS, 2019). Mandatory mixing of recyclates into virgin feedstock is also already proposed for the packaging sector, and could also act a powerful way to promote further use of recyclates.[2]

[2] https://ec.europa.eu/commission/presscorner/detail/en/qanda_22_7157

| Value chain stage | Ecodesign consideration | Criteria |
|---|---|---|
| Plastic feedstock processing/upgrade | • Use recycled material as feedstock<br>• Produce recyclable feedstocks | • Increase in recycled %<br>• Increase in recyclable % |
| Product manufacture | • Decrease material/energy use<br>• Use recycled/recyclable feedstocks for plastics | • Lower CO2 footprint per product<br>• Increase in recycled %<br>• Increase in recyclable % |
| Consumption (inc. repair, reuse) | • Increase information<br>• Extend product lifetimes | • Increase in product use time<br>• Information, labelling |
| Post-consumer collection (inc. component reuse, refurbishment) | • Improve take-back systems | • Increase in collected % of sold products<br>• Increase in reused and refurbished % of components<br>• Increase in recycled % of post-consumer materials |
| Post-consumer material sorting and pre-treatment | • Improve separation process<br>• Increase recycled portion<br>• Increase the purity of recyclate | • Increase in recyclate value<br>• Increase in recycled % of input flow |
| Material recycling | • Promote advanced processing: Pyrolysis rather than incineration | • Lower CO2 and higher energy output<br>• Less loss in embodied energy |
| | • Improve material quality | • Increase in material value |

**Table 5. The revised ecodesign considerations to promote circular plastics.**

## Conclusions

To promote the targets of EU circular plastics strategy and to improve the recycling of plastics in WEEE, ELV, C&DW, the general ecodesign recommendations were summarised into four actions: design products and systems for longer lifetimes; make products easier to recycle; close the loop through recycled content; and focus on chemicals for circular products and materials. More detailed considerations were produced in regard to specific life-cycle phases of circular plastics. In addition to the work on ecodesign strategies, more broad policy recommendations were also developed (zu Castell-Rüdenhausen & Marttila, 2023). Lastly, a website was produced to disseminate the recommendations (see: https://www.nontox-ecodesign.org/).

## Acknowledgments

The NONTOX project has received funding from European Union's Horizon 2020 research and innovation programme under grant agreement N°820895.

# Design of e-textile and printed electronics applications for their life cycle

**Max Marwede[(a)], Maria Smolander[(b)], Liisa Hakola[(b)]**

a) Fraunhofer IZM, Berlin, Germany;

b) VTT, Technical Research Centre of Finland Ltd, Espoo, Finland

**Keywords**: Printed electronics; E-textiles; Sustainability; Life cycle, Eco-design.

**Abstract**: Innovative technologies such as printed electronics on thin and flexible substrates and conductive yarns, threads or fabrics allows the use of electronics in new applications such as textiles, smart packaging, or single use medical products. However, the lifetime of the original product and the add-on electronics are not always compatible. In this paper we explore typical applications of the above mentioned technologies and their related use patterns and life-times. We identify related environmental challenges and potential benefits for typical applications (SWOT analysis) and we describe eco-design strategies and provide practical design examples. The research shows that it is quite probable that current commercially available wearables such as smart watches or fitness tracker are used way shorter than their potential technical lifetime due to aesthetic, functional or usability reasons. To avoid this "premature obsolescence" of new wearable applications based on technologies still in research and development, we propose several eco-design strategies which a) should reduce the environmental footprint of the devices and b) enable reuse, repair and recycling of the devices, parts and materials. Those include the choice of sustainable and safe materials, resource-efficient design strategies, strategies to extend the use time e.g. through high reliability, timeless design and enabling repair and reuse through modularity. Finally different end-of-life eco-design strategies to enable composting or material recycling are presented. This paper should support researchers and product designers to develop more environmentally friendly materials, technologies and wearable applications.

## Introduction

### *Motivation*

Electronic products are no longer indispensable in our world. They enable measurement, communication and control of millions of use cases and applications and propelled us in the 21st century, where now and in the future artificial intelligence will even accelerate the use and interpretation of data amongst other sourced from distributed sensor systems (IoT). However, this vision of a seamless integration of the digital with the physical world will not come without environmental costs. The environmental impacts of electronic products include amongst other the sourcing of critical materials and conflict minerals, the use of hazardous substance during the manufacturing stage, the energy consumption and related greenhouse gas emissions during the use phase and improper disposal and treatment of electronic waste.

According to the United Nations in 2019 alone, the world generated 53.6 million metric tons of e-waste, growing by 2.5 million tons each year from which only 17.4% of e-waste generated in 2019 was formally collected and recycled (UNU & ITU, 2023). The green house gas emissions related to the life-cycle of ICT was estimated to account to 2.6% to 3.6% of global green house gas emissions in 2020 (Belkhir & Elmeligi, 2018). The fast growth of new technologies could raise the demand for specific materials substantially. Just to give one example: the demand of Indium for displays, opto-electronics and thin-film phototovoltaics could grow from 207 tons in 2018 (18% of total indium production in 2018) to 330 to 440 tons in the year 2040 (Marscheider-Weidemann, 2021).

While the number of IoT devices is growing rapidly (Transforma Insights, 2022), it is widely discussed in society, politics and science that product design, trends and technology advancements can lead to premature obsolescence of the devices. This development is countered for example by the "right to repair" movement in the USA and Europe (Right to Repair Europe, 2023) and policy initiatives such as the proposal for an Regulation on Ecodesign for Sustainable Products focusing amongst other product categories on textiles (EC, 2022a) or the Proposal for a Directive on Substantiation and Communication of Explicit Environmental Claims (Green Claims Directive, 2023). France for example introduced a repairability score for several electronic and electrical products in 2021, which will be replaced by a durability score in 2024 (ECC-Net, 2023).

Innovative technologies such as printing of electronics on thin and flexible substrates to make flexible circuits (printed electronics) or conductive yarns, threads or fabrics (e-textiles) allow the use of electronics in new applications such as garments, smart packaging, wearable medical, sports or safety products. While this is still a comparatively small market compared to "standard" electronic technologies and products, the market potential is expected to be growing exponentially. For instance, BCC states that the global flexible electronics market is expected to reach $54.2 billion by 2026 from $30.5 billion in 2021 at a compound annual growth rate (CAGR) of 12.1% (BCC Research, 2023).

The vision of a ubiquitous but "invisible" use of electronics might be appealing because of benefits such as form factors fit to the human body, the more seamless interaction with the "artificial" environment, for the health and wellbeing of people (and animals) or the better observation of environmental conditions such as air or water quality.

On the other hand, it can also mean that resource and carbon intensive, potentially hazardous and difficult to recycle electronics will be embedded into various objects and environments. Thus, there is an outstanding chance and the need to develop "sustainable" technologies and solutions at this early stage of the market.

This paper attempts to analyse typical applications for those new technologies focusing on "wearable devices", the related expected use and lifetime, the potential environmental benefits and challenges compared to standard electronics and propose eco-design recommendations derived from literature and own research projects.

## Description of different technologies

### *E-Textiles*

**E-textiles** refer to fiber, yarns or fabrics with embedded electric functions. Those functions can be embedded into textiles through a variety of methods, including sewing, weaving, knitting, embroidery, coating, laminating, printing, braiding and chemical treatments (Goncu-Berk 2019). The main electric function of current commercial textile technologies available is conductivity. Typical materials used to realize conductivity are silver, copper, carbon, gold, nickel and PEDOT that are coated on or embedded in yarn to make threads or woven fabrics. Typically, common standard electronic components such as LEDs, sensors or complete miniaturized circuits are interconnected with various technologies such as stitching, cramping, gluing, welding, lamination, or soldering (Stanley et al., 2022) to the textile conductors in order to realize the electronic function of the final garment.

There are however also textile materials with more advanced electric functions such as yarn transistors, photovoltaic fibres, or textile sensors in the research & development stage. Newer materials used are carbon nanotubes (CNTs), low-dimensional layered materials (graphene, transition metal chalcogenides, etc.), and mechanically stable inorganic materials which have been applied on fibres (Heo et al., 2018).

Application examples of e-textiles include monitoring health status of patients, tracking body functions, speed and routes for professional sports, and safety applications (Eppinger et al., 2023)

The integration of added electronic functions into textiles can potentially add value to the user and thus extend the use time of the garment, but can on the other hand also lead to premature obsolescence due to functional or aesthetic reasons.

*Printed and hybrid electronics*
Whereas current electronics products are basically rigid devices based on circuit boards printing and hybrid integration (i.e. chip-on-foil) based manufacturing methods enable realization of electronic products that are flexible, soft, conformable, and even stretchable (for instance Behfar et al., 2021; Gillan et al., 2022). Due to the bendability and flexibility, these devices can, for instance, be used as smart patches directly on skin to measure various parameters from a human body such as temperature or heart rate. Manufacturing methods compatible with roll-to-roll (R2R) processes enable also scalable manufacturing of diagnostic devices e.g. for point-of-care applications.

**Wearables** are often realized with a combination of the above mentioned technologies. Smartwatches and fitness trackers are still dominated by traditional miniaturized rigid electronic systems, but electronic plasters and e-tattoos, medical shirts, smart contact lenses, and exoskeletons are only few examples where those technologies are combined. On the one hand this new level of system integration promises to reduce the complexity, weight and process effort compared to standard electronics, but on the other hand if sustainability is not taking into account will create products with new material composites and short life-cycles becoming obsolete through trends and fast technological advancement and thus contributing to global resource depletion and e-waste accumulation. (Schischke 2019, Eppinger 2023).

Therefore, we asked ourselves whether it is possible to identify eco-design recommendations for different types of wearables based on e-textile and printed electronic technologies depending on their life-cycle and expected lifetime.

In order to answer this question, we

a) first searched for typical types of wearables and use cases;
b) identified characteristics, which differentiate them from each other;
c) identified environmental challenges for each use case;
d) Identified eco-design strategies for each use case;
e) and provide practical design examples

Our perspective is environmental sustainability. Here, we will focus mainly on technical or product design related challenges and leave out questions related to change in systems (e.g. recycling systems or circular business models), and other design related aspects such as usability, aesthetics or behavioural aspects. All those factors do of course influence how long a product will be used but go beyond the scope of this paper.

## Comparison of wearable device types and their lifetimes

Current commercially available wearables already cover a wide range of applications and form factors. For hobby health and sport use there are smart watches, bracelets and even rings, which measure physiological parameters such as heart rhythm (ECG), skin temperature or blood oxygen. The technologies used here are usually still miniaturized standard rigid electronics on standard or flex PCBs (printed circuit board) connected with flex cables.

Commercially available **e-textiles** usually still combine textile-based conductors and sensors for example embedded in wests, t-shirts or chest straps combined with a “rigid” system of standard electronics for power, reading out and transmitting the signals (e.g. through Bluetooth). This “module” is usually connected to the textile with a reversible interconnection system such as snap buttons (see for example Figure 1).

In recent years stretchable skin patches or electronic tattoos have been reported. They enable direct, conformable contact with skin and ultimate convenience during use. Mechanical design, integration strategy and signal pathway play a crucial role in upscaling these developments (Gillan et al., 2022; Huttunen et al., 2022). Table 1 gives an overview of different types of typical applications of the above mentioned technologies.

**Figure 1. Movesense Medical ECG (figure Movesense).**

**Table 1: Different types of wearable applications based on e-textile and printed electronic technologies**

To our knowledge, there is apparently no public research data available on the use-time of wearables such as smart watches or bracelets (fitness tracker) – the most common devices currently on the market. The average lifespan of smart phones ranging from 2 to 3.5. years might serve as proxy for smart watches (Schischke 2019). A short research on platforms for refurbished products showed that the Apple iWatch Series 2 released in 2016 and produced until 2017 (madeApple, 2023) is still sold meaning that the technical functional lifetime of this model can be 6 years and more – certainly depending on its use intensity.

A survey in the year 2013 in the US reveals that more than half of U.S. consumers who have owned a modern activity tracker no longer use it. A third of U.S. consumers who have owned one stopped using the device within six months of receiving it (Endeavour Partners, 2017). Another analysis of sales advertisements of health trackers on Craigslist in the US showed that 20 % of offered devices were new (not used), and about 30 % were only used days to months (Clawson et al., 2015). According to other studies around that time, reasons for early abandonment for wearables are unattractive design, useless functions and difficulty to use and care (Gurova et al., 2020; Koehler et al., 2015; Page, 2015; Perry et al., 2017). Some of those "issues" might stem from products and technologies not yet being fully mature at that time. We fear however, that this picture has not changed a lot. Like for other electronic devices, they most probably end up hibernating in drawers and cupboards (see for example (Casey et al., 2019)).

There is no public data available for the use time of e-textiles – probably due to the low market penetration of commercial existing products. The fear is however, that aesthetics, technical or functional reasons can negatively influence the use-time of the e-textiles. The technical lifetime of the e-textile is certainly limited by the shortest lifetime of any individual component – either the wearing out of the actual textile, failing interconnections to the electronic components or the failure of electronic components itself (and maybe the required software), especially in case it cannot be repaired.

The active use time of smart patches for medical use can be as short as few minutes or hours but typically the patches need to be attached on skin for few days or even couple of weeks. E.g. the Freestyle glucose sensor can be worn for 14 days (Abbot, 2023). Selection of the skin adhesive plays a crucial role when defining the feasible use time of the patch. Adhesive should be strong enough to ensure the attachment to the skin but on the other hand they need to be non-irritant and non-sensitizing during the use and removal. Wear time can be limited by the battery capacity to few days (Analog Devices, 2020).

## Related environmental benefits and drawbacks of skin patches and e-textiles

*General for both e-textiles and skin patches*

(Schischke et al., 2020) summarized potential negative environmental impacts of flexible and stretchable electronics as well as e-textiles. The negative impacts also applicable to the above mentioned technologies are:

- The choice of conductive materials, especially due to the high carbon footprint of the raw materials Ag, Au, In and Pd.
- The energy input for the purification processes, or the realization of specific molecular shapes and microstructures, (e.g. graphene, silver nanoparticles or eutectic GaInSn).
- The toxicity of materials such as electrolytes in flexible batteries and super-capacitors or hazardous solvents in inks (Byrne et al., 2016; Schulte et al., 2013; Tsai et al., 2016) – released as emissions during production, in case of defects and/or at end-of-life.
- The biocompatibility of the used materials.
- Electromagnetic fields during the use phase.
- The potential release of nano-particles during processing, use or end-of-life.

Devices should be designed for compatible with current established recycling processes and have to fit to current recycling streams. As long as there are no massive waste streams of skin patches and e-textiles, it is unlikely that specific recycling technologies will be developed for those devices. Typically, those devices will be treated as electronic waste – in case it can be easily identified as electronic waste by the user. Missing awareness and high effort for the correct disposal might lead to devices ending up in municipal waste streams. Especially *e-textiles* might also end up in textile waste collection, causing potential issues in textile sorting and recycling. Also standard e-waste treatment technologies might not be able to handle "flexible" devices as they are built to crush and sort rigid products. In case of medical applications in a professional context, devices are usually treated as medical waste, which is incinerated due to potential contaminations or first needs to be sterilized before recycling. Important to mention is that recycling does not "offset" the environmental footprint created during production and use.

The environmental benefits of state of the art wearables lies in the miniaturization of the electronics and such the lower material demand. The carbon footprint of the full life cycle of the Apple Watch Series 7 (GPS + Cellular) is 34 kg $CO_2$ eq (Apple, 2021) compared to an iPhone 12 mini with 64 kg $CO_2$ eq (Apple, 2020).

In case of the iWatch, 76 % of the carbon footprint is owned to the production (Apple, 2021). Another LCA of a smart watch shows that 84 % of the overall carbon footprint stems from the PCB, which is also accountable for most of the metal depletion (Ma et al., 2017). So, the main contribution to the carbon footprint are the electronics.

Of course, the performance of the two devices differ from each other and probably all users have a phone and a smart watch. So smart watches currently rather add to the overall carbon footprint per person instead of substituting a smart phone.

**E-textiles**

Over the last decades, research and development of e-textiles focused on increasing comfort, reliability, and washability. Washability is still one of the most challenging features to realize. The development goes towards a higher (seamless and permanent) integration of electronics into the garment – also developing new functional textile materials (e.g., based on graphene) which adds to the complexity of the material composition. Already regular garments are difficult and costly to recycle due to the variety of the materials (fibres, zippers, buttons etc.). The seamless integration of electronics will make it even harder to recycle. Also repair becomes more difficult increasing the likeliness or irreversibly damaging the textile or the electronics.

Furthermore, current collection and recycling systems are designed for either electronics or textiles, which might lead to technical problems and contaminations of recycling streams in both systems. Given the still low market volumes it is unlikely that specialized processes will be developed for e-textiles. Besides, for the user it might not always be obvious that the garment is electronic waste, and the garment might enter the textile recycling route or end up in household waste. (Eppinger et al., 2023; Gurova et al., 2020; Schischke et al., 2020)

Potential environmental benefits can arise from the high integration and miniaturization and the alternative "textile based" manufacturing processes. Creating circuits based on conducting threads, yarns or textiles might be more environmentally friendly than the very energy and chemical intensive PCB manufacturing process. However, to the knowledge of the authors there is no LCA based comparison of a PCB circuit with a textile circuit that can proof those claims. Another potential (social) benefit can arise when the new e-textile technologies are combined with local handcraft, local manufacturing and locally sourced materials leading to shorter supply chains and thus lower transport emissions and potentially less overproduction.

**Skin patches based on printed electronics**

As described above printing and hybrid integration-based manufacturing methods enable soft, conformable, and even stretchable concepts as skin patches or electronic tattoos. Regarding the environmental impact, it has been claimed that the main sources of climate impacts and sustainability challenges in the printed electronics stem from fossil-based substrate materials and the metals used (Nassajfar et al., 2021). However, printing based manufacturing methods enable the use of several different substrate materials, including renewable materials, as printing substrates for improved environmental impact. For instance, (Jansson et al., 2022) investigated the use of re-pulpable, paper-based substrates in printed electronics. They compared the printability and performance of metal conductor layers on different paper-based substrates with those on plastic foils. Despite their higher roughness and porosity, print quality and layer performance was equal or even better than on the reference PET substrate. Another approach was taken by (Jaiswal et al., 2023) who exploited a fully biobased and biodegradable cellulose based substrate for an ECG device demonstrator. In this work the soil-burial test indicated full degradation of the cellulose based substrate hence enabling a potential recovery strategy for the non-degrading components and metallic ink. (Immonen et al., 2022) and (Luoma et al., 2023) investigated the use of different biodegradable and biopolymer substrates for printed electronics.

(Nassajfar et al., 2021) carried out an LCA study of conventional PCB production and compared it with additive, printing based fabrication method with PET, PLA and paper based substrates. They concluded that the environmental impacts of the additive method are about five times lower than those of conventional PCB production, difference arising especially from reduction in energy demand in the additive printing based process. In printing based manufacturing schemes silver nanoparticle as the conductive metal had the highest contribution to the environmental impacts.

Table 2 summarizes the potential sustainability strengths, weaknesses, opportunities and threats of e-textiles and printed electronics

| **Strengths** | **Weaknesses** |
|---|---|
| • Minimize use of electronics for same function (high integration, miniaturization) **(ET)**<br>• Efficient and “simple” manufacturing technologies compared to typical PCB assembly (**ET,PE**)<br>• Simplification of wearable IoT solution (computing power in the cloud) **(ET, PE)**<br>• Durability: high integration for washability, comfort & function **(ET)** | • Standard rigid electronic components are designed for non-textile applications (questions of reliability, toxicity, washability, low compatibility with textile haptics and aesthetics) (**ET**)<br>• Potential emissions from laundry (e.g., release of microparticles, which pass through wastewater treatment plants) (**ET**)<br>• „Seamless integration“ of electronics into textiles hampers disassembly of different component, repair and recycling (**ET**)<br>• Mixed material composites (metals, polymers, natural fibres) hampers material recycling (**ET, PE)** |
| **Opportunities** | **Threaths** |
| • Sustainable applications: medical, health and safety **(ET, PE)**<br>• Small-scale, local, and on demand manufacturing **(ET, PE)**<br>• Small footprint products: lightweight, flexible, leading to energy savings during use **(ET, PE)**<br>• Decrease in use of resources (materials, energy) **(ET, PE)**<br>• Circular and modular designs **(ET, PE)**<br>• Strong EU support through relevant sustainability legislation and agendas **(ET, PE)** | • Combination of fashion (fast changing trends) with longer living electronics (--> premature obsolescence) (**ET**)<br>• Shortcomings of durable integration of electronics and a lack of standards to analyse the performance (**ET, PE**)<br>• Lack of standards for labelling, sustainability, reliability, interconnection technologies, … (**ET, PE)**<br>• E-Textiles should be handled as e-waste, but lack of knowledge/awareness on producer and consumer side (**ET**)<br>• No recycling technologies in development, not recyclable with current processes in textile or e-waste recycling (**ET, PE**) |

**Table 2. Sustainability SWOT analysis of e-textiles (relevance indicated as ET in the table) and printed electronics (indicated as PE) (Eppinger et al., 2023; Gurova et al., 2020; Marwede & Hoske, 2021; Schischke et al., 2020)**

## Proposal of eco-design strategies for wearable e-textiles and printed electronic devices

Several recommendations have been proposed for eco-design of e-textiles and printed electronics e.g. by (Gurova et al., 2020; Hakola et al., 2022; Marwede & Hoske, 2021; Schischke et al., 2020). In this chapter we discuss the most relevant recommendations for e-textiles and skin patches based on printed electronics as well as examples and possible ways to implement them.

**Choice** of **sustainable** and **safe materials**

- Use of recycled materials (fibres, polymers)
- Reuse electronic components from retired consumer electronics.
- Use of renewable or biobased materials in case of environmental benefits compared to non-renewables (taking into consideration recyclability of new renewable materials e.g. of biopolymers).
- Check toxicology of substances used for the development of new materials and find potential substitutes (e.g. by using the “Safe and Sustainable by Design Framework” proposed by the European Commission (EC, 2022b)).
- Use materials compatible with manufacturing processes (e.g. lamination, printing) but choose option with lowest environmental impact.

**Resource-efficient design**

- Reduce overall number of components and material types
- Avoid the use of batteries: use energy harvesting instead (e.g., printed photovoltaics, thermoelectric or piezoelectric generators, induction)
- Use of wireless interconnection for edge or cloud computing of the data to „minimize“ the use of ICs in the garment
- Resource efficient pattern making both for garments and printed electronics (avoidance of off-cuts)

**Extending the potential use-time**

- Fostering reusability, durability, maintainability and reliability in order to minimize the environmental footprint per use.
- Allow for technological independence or multi-platform usage to avoid technical or software obsolescence - e.g. applications should be compatible which major operating systems (Android, iOS).
- Use durable and robust interconnection technologies for parts intended to function for the lifetime of the product. Relevant information and tools for care, repair and maintenance should be available.

For *e-textiles* also aesthetics and style are relevant, but in order to avoid that the garment becomes out of fashion, the garment should be designed in a timeless manner and in a classical style. Other important aspects are multifunctionality, ease of use and comfortability. If possible, the garment should be customizable for higher attachment (e.g. colour- and pattern changing textiles, silhouettes, fit or size changing). The choice of textile materials that require less laundering can also help to avoid physical stress and corrosion for the electric and electronic parts. For *skin patches* the usage time can be extended e.g. by optimal skin adhesive in terms of durability and minimal skin irritation

One good option to enable **repairability** of *e-textiles* or *skin patches* is a “modular approach” separating the components which are “critical” for the desired wearable function (e.g. sensors, conductors) and might have a shorter lifetime from other functions (e.g. interconnectivity, microcontroller, energy supply). Those two parts should be reversible detachable from each other for re-use, repair, replacement or upgrade.

Allow for **reuse** of product and components (low degree of integration) for those parts whose original production had a significant environmental footprint (e.g. semiconductor components, PCBs) or for materials that are not recyclable (e.g. composites). Reversible electrical and mechanical interconnection technologies such as snaps, crimps, or zips can be used to facilitate reuse. In case of using „consumables” (e.g. electrodes) enable either reuse (e.g. washing, disinfection, reactivation of adhesion) or in case the consumable needs to get disposed and cannot be recycled, use low environmental impact, non-toxic materials or compostable materials.

For *skin patches* a possible way of implementation reuse is creating a strategy for component recovery e.g. by biodegradation (Jaiswal et al., 2023). Further, modular systems combining e.g. single use tattoo electrodes as described by (Huttunen et al., 2022) combined with durable, still stretchable electronics as described by (Behfar et al., 2021).

One modular eco-design example for *e-textiles* is the ALMA project (ALMA, 2023) realized within the European STARTS project Re-FREAM (Re-FREAM, 2023). ALMA is an underwear for measuring the pH value of vaginal fluids to detect infections using a novel non-invasive pH sensor developed by the University of Cambridge (Che et al., 2018). The thread based sensor-electrodes as well as the textile integration of the electrodes and the stitched RFID antenna was realized at Fraunhofer IZM. The sensor inlay is removable for washing. The whole electronic module including the microcontroller (WISP Wiki, 2023) can also be reversibly removed, because it is just snapped to the textile. Furthermore, it was tested whether the RFID antenna can be used to power the module and read out the signal to avoid a battery close to the body.

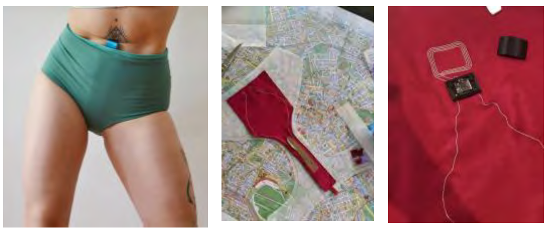

**Figure 2. Design of the ALMA Demonstrator © Guilia Tomasello**

Products should be designed for compliance with state-of-the art **end-of-life collection and recycling systems** and recycling processes should be co-developed for new materials and technologies. *E-textiles* and *skin patches* should be easily recognizable as electronic products by the user, during sorting and recycling e.g., through labels. Integrated electronics should be recognizable (by eye or used sensor technologies in the recycling industry) and (mechanically or manually) detachable during pre-treatment so that different materials end up in the correct recycling streams (e.g. polymers, natural fibres, metals/electronics).

For *printed electronic labels and patches* intended for single or short-term use, the compatibility of different, existing end-of-life options need to be carefully evaluated. E.g. in Ecotronics project (Hakola et al., 2022) end-of-life scenarios for smart labels in mixed waste, plastic waste, cardboard, glass waste and metals recycling were discussed in terms of the metal recovery and nature of the substrate material. It was concluded that there is potential to recover electronic materials from the waste streams but required technologies do not yet exist. Practical studies were also carried out to investigate the repulpability and deinking of fibre-based smart labels. It was found out that substrate selection influenced the repulpability. In addition, the effects of possible ink residuals (e.g. shortcuts) on re-use as printed electronics substrates need to be taken into account. Bigger electronic components, such as chips or batteries, could be blocked in the sieving systems to be disposed by burning or on landfill, but the downside is that the components and materials are lost from circularity (Aliaga et al., 2015).

If **compostability** is a goal, a) it must make sense for the use case and b) the whole system must be compostable. Otherwise, recyclability should be the focus. If the use of the printed electronic device involves a risk of microplastic release biodegrading substrates can be considered as alternative carrier materials instead of conventional plastic materials or FR4 (Immonen et al., 2022; Jaiswal et al., 2023). One potential end-of-life alternative for biodegradation is the use of solvable materials and dissolution of devices into organics and nontoxic metals (Schischke et al., 2020).

## Summary, Discussion and Conclusions

Scope of this paper was to give practical recommendations how to enhance the sustainability of future wearable electronic systems i.e. skin patches and e-textiles. Figure 3 summarizes the main recommendations for the eco-design of wearables to enable closing the loops for products, components and materials (circular design).

E-textile design and development must take into account the sustainability of both the textiles and the electronics and also more fashion, aesthetic and usability related aspects. Those considerations included the whole life cycle from material choice and development to end-of-life solutions. Specific to textiles and fashion are "design for attachment and trust" strategies or "slow fashion" principles.

Especially, seamless integration of electronics into textiles can be questioned from a sustainability point of view (although it might be better for reliability, functional or aesthetic reasons). Here, one needs to find a good balance between comfort, function, & reliability and washability, repairability & recyclability.

For both technologies it is important to understand the usage patterns (daily, intermittent, single use), user needs (function, usability, comfort, …), desired technical life-time (hours or years) and use conditions (temperature, sweat, physical stress, …) and the most probable end-of-life scenario for the later application.

To improve the sustainability of the application it is furthermore important to

a) develop solutions which "substitute" less environmentally friendly solutions currently used (e.g. bigger equipment in hospitals),
b) develop applications with an added environmental or social benefit (e.g. better health), and
c) avoid that the new devices actually "doubles" functions of another product (e.g. smart phone) which will be used in parallel, i.e. it should rather complement the other device.

Overall, the described technologies offer great potential to develop more environmentally friendly products closer to human needs. However, if sustainability is not considered, they will rather add on to the environmental problems such as resource depletion, climate change, persistent chemicals in the environment and food chain and e-waste piling up. Thus, we strongly ask researchers as well as product developers to consider sustainability in the early development phases because once decisions are taken, changing those in the later phases (e.g. to comply with stakeholder needs and upcoming regulations) mean higher efforts and costs.

# The 'right to self-repair' or a 'comprehensive guarantee'; why should 'iFixIt'?

**Neil Maycroft**
University of Lincoln UK

**Keywords**: ‘right to repair’; Moles; Comprehensive Guarantee.

**Abstract**: My paper offers a critique of the demand for a right to self-repair as a route to extended product lifetimes. 'Right to repair' advocacy is strongly oriented to 'self' repair. Rhetoric of the kind 'if you can't repair it, you don't own it' is commonplace. The barriers to self-repair highlighted are 1) lack of information (repair instructions and diagrams), 2) lack of parts and tools and 3) products not designed and manufactured for repair. If these barriers are removed via 'right to repair' legislation there will be a resulting, dramatic increase in self-repair it is argued. However, there are other barriers which are not product or design-centred. How to develop the initial motivation to self-repair? How to find the time needed for repair? And what about the extra consumption needed for self-repair? The demand for self-repair can also be regarded as an unwanted imposition as one attends to other disruption resulting from the breakdown of goods. Capitalists try to limit their liability for product durability and the move towards self-repair could be a route to offloading the burdens of current liability—'we've made the diagrams, tools and parts available, so 'you now own it, so you fix it''. One response is found in Abraham Moles' idea of the 'comprehensive guarantee' which radically extends producer liability. Moles conceives of two repair realms. The first, covered by the comprehensive guarantee, places liability for repair onto producers; it cannot be offloaded to third parties or consumers. At the end of the guarantee period goods pass into a secondary status which would be the realm of self-repair with costs and responsibility passing to the user. My paper places these two approaches in a creative and critical encounter.

## Introduction

To offer a polemic against self-repair seems perverse given the ubiquity of repair practices in society (Krebs & Weber, 2021) and the long-standing academic interest in it (Richardson, 1980, Graziana & Trogel, 2019). However, a critical social theory of repair may be insightful and here I offer the beginnings of one in relation to some aspects of 'self', 'home' or 'consumer' repair.

I am interested in the assumptions that product and design-centric approaches to products—in relation to consumption, use, maintenance, repair, storing and wasting—make about the people engaging in those practices. This interest was provoked when I was recently asked to review a journal article which asked 'might repairing things repair people' and which led to me asking myself what kind of consumers/users/owners do long-lasting products require? Often, while advocating design solutions to the problems of poor durability, obsolescence, waste and irreparability, the idea of the user as a potential correspondent in the implementation of these solutions in the everyday life of product consumption, use and disposal remains assumed or unexamined.

## Right to repair rhetoric

The demand for goods designed to facilitate repair joins calls for other product-focused solutions advocated to extended product longevity. These design and product centric approaches argue that re-designing products will foster significant and preferable consumer behaviour (Pozo Arcos et al., 2021). Advocacy has included design for modularity, design for disassembly (De Fazio et al., 2021), design for stewardship (Lane & Watson, 2012), for engagement, for product resilience (Haug, 2018), for upcycling (Sung et al., 2019), etc. There are clear tensions from a design and manufacturing perspective. Design for repair generates different recommendations to those for design for resilience which imagines products not needing repair. Design for repair sits uncomfortably with design for upcycling whose practices depend on steady streams of predictable waste. The application of design-led repair guidelines itself would not be uniform with different recommendations for electronic products, clothing and automobiles for example. Similarly, the guidelines and designed material results that foster the most effective professional repair potential of products are likely to be different to those aimed at self-repair and, again, will be different across different products. So, there is no one 'design for repair' or 'design for self-repair' but, repair is offered as a solution to some of the symptoms of short product lifetimes while the circular economy is offered as the cure. However, while there are reasoned critiques of the circular economy (Valenzuela & Böhm, 2017, Corvellec et al., 2021), repair is widely regarded as the 'stuff of common sense' (Isenhour & Reno, 2019).

The claim made for a 'right to repair' is strongly oriented to 'self' repair of digital and electronic goods. Rhetoric of the kind 'if you can't repair it, you don't own it' is commonplace. A set of allied claims including 'repair teaches engineering', 'repair is war on entropy', repair 'requires creativity' are often advanced too. However, the claims made for self-repair or 'home' repair promise more than preferable consumer behaviour. A central claim is 'repair connects people and things' with resulting beneficial effects which go beyond the specific desire to repair a particular object. Practices of care, maintenance and repair bind consumers closer to their products through the development of attention, skill, tacit knowledge and focal practices it is claimed. So, self-repair itself is seen as a route to consumers' increased stewardship, engagement and product responsibility. Self-repair is made to represent both the literal closing of the space between people and things through a recovery of the materiality made distant by commodity production, and the closing of an historical gap with an imagined less wasteful, 'hands-on' past (Tonkinwise, 2018). The barriers to self-repair highlighted are 1) lack of information (repair instructions and diagrams), 2) lack of readily available, 'reasonably' priced parts and, 3) products not designed and manufactured for repair (non-standard fastenings, irreversible construction, the need for specialised tools). If these barriers are removed via 'right to repair' legislation, there will be a dramatic increase in self-repair it is argued. Overcoming these barriers is central to recommendations found in current and proposed EU consumer protection legislation (Keirsbilck et al., 2020, Montoya, 2023).

## Motivation, attention, skill and time

These external material barriers can act to undermine a 'propensity to repair' where it exists (Scott & Weaver, 2014). However, there are other barriers which are not product specific or design-focused and which can undermine worthy attempts to remove the above 'material' barriers (Cooper & Salvia, 2018, Hernandez et al., 2020): how to develop the initial motivation to self-repair if that propensity is not present, how to develop the cognitive and practical skills needed, how to find the time needed for repair?

Repairing things demands attention, skill and time. Self-repair is often advocated as a practice that will develop attention and skill. However, one needs the propensity to develop attention and skill before directing that motivation at particular ends. Of course, the desire to self-repair might provide that motivation and is often reported in relation to repair cafe attendance (Madon, 2022) but that desire does not of itself guarantee the attention and skills required are present or forthcoming (Crawford, 2015). And while repair demands both cognitive acuity and embodied action, we have good evidence that capacities to act successfully in the world in these ways are under threat. It is a world in which we are losing our sensory and motor skills in relation to food (Wilson, 2022), where those who train surgeons lament the poor level of skills needed for cutting and stitching among medical students (Coughlan, 2018) and in which observed motor competence among children is significantly declining (Duncan, 2022).

Attempts to reshape our attention and to direct it in particular ways, especially towards consumption of various kinds are long-standing, historical features of capitalism (see Curran, 2023 for a good overview). According to Crawford (2015) “Without the ability to direct our attention where we will, we become more receptive to those who would direct our attention where *they* will” (p. 16, emphasis in original).

Techniques to direct our attention have grown in intensity, ubiquity and scope since the widespread adoption of digital, screen-based devices. Crawford argues (2015) “...in a culture saturated with technologies for appropriating our attention, our interior mental lives are laid bare as a resource to be harvested by others" (p. 247). It is ironic that much self-repair advocacy is aimed at restoring function to devices which actively reorganise our attention and undermine the development of our motor skills (Coughlan, 2018).

The 'cognitive demands' repair work, which rely on sustained and directed attention, are also easily overlooked. The material properties of the objects being repaired, the use of tools, material constraints and variations in the repair process and the 'push-back' of the material world each contribute to the development of the 'practical wisdom' associated with skilled repair work. We see this both historically in repair practices such as the visible mending of kintsugi or sashiko and in the contemporary world of skilled, professional and invisible repair work carried out in the repair industries. Repairing a mechanical clock tells one much both about how it works and its components with their often-recalcitrant material qualities. Likewise skilled darning of clothes offers a lesson in garment construction, the material qualities of threads, hand-eye coordination, etc. Repairing a smart phone does not offer this richness of experience; function remains opaque, the materials are standard components and non-disclosing of their properties. The experience of repairing things remains separate from the experience of the things needing repair. For Crawford, though generously and sincerely offered, much repair guidance is driven by an "if-then logic" which aims to make a repairer a "...part of a mechanistic *replacement* for individual mind" (2009, p. 175 emphasis in original). Redesigning digital consumer goods to facilitate self-repair and making tools and manuals more widely available may not lead to the mass culture of self-repair that is proclaimed if self-repair is seen as a boring, unrewarding chore.

Repair also requires time. Professional repairers are paid for their time, self-repairers must find the time (along with the motivation, tools, parts, etc.) to repair. That this time is both available and ready to be oriented to self-repair remains largely unquestioned. This is in relation to both an individual's circumstances where there may be very little time available for self-repair even if the motivation is present and to the amount of social time available for the self-repair of the hundreds of millions of consumer goods to which the right to repair is oriented. I once attempted an 'iFixIt' phone repair. First, I did not have the specialised tools and it did not seem a worthwhile economic cost to avail myself of them. Second, I was advised to put aside over three hours to carry out this repair by proxy. I did not have that time, and should I have I would not have spent it repairing my phone. It turned out that a thirty second hack 'repaired' my phone which raises questions concerning the accurate diagnosing of consumer goods' faults.

The idea that if we provide consumers with the tools, instructions, parts—and even easily repairable goods—that they will take up home repair deserves more thought. Who will provide the time, skills and attention needed, especially for consumers who regard the acquisition of these attributes, and the practice of repair, as 'costs' they do not want to bear?

## The comprehensive guarantee

Capitalists try to limit their liability for product durability and the move towards self-repair could be a route to offloading the burdens of current liability—'we've made the diagrams, tools and parts available, so 'you now own it, so you fix it''. This increasing tendency of advanced economies to regard individuals as responsible for all aspects of their lives is offered as 'freedom'. However, this apparent 'autonomy' is questionable.

"Autonomy talk speaks the consumerist language of preference satisfaction. Discovering your true preferences requires maximizing the number of choices you face: precisely the condition that makes for maximum dissipation of one's energies" (Crawford, 2015, p. 25).

Adding choices about repair and the supposed autonomy of it adds to this situation in which ones' energies can be further dissipated. And the irony is that much of the design for self-repair talk concerns precisely those products that undermine our ability to fully developed our situated and embodied attention—phone, tablets, tv, computers, etc. It is the opposite of design for autonomy (Pierri, 2019).

However, the right to repair need not be synonymous with self-repair. It could be 'the right to repairs' as in Abraham Moles' idea of the “comprehensive guarantee” (Moles, 1985). Moles was a French polymath academic whose writing was briefly popular in design studies scholarship in the mid 1980s but has since been largely overlooked. Moles argues that products needing repair are detrimental to the quality of life in two ways; 1) the initial failure and 2) the costs, including time, of addressing the failure. he offers the comprehensive guarantee as a solution. This guarantee,

> *...stresses how the quality of life is impaired by the failure of a particular tool or object...large manufacturing companies have reduced their prices by surreptitiously shifting some of the burdens that are bound to the use of complex mechanical or electronic objects from their shoulders to those of the user. This user must take action if something goes wrong with the article...(1985, p. 56-57).*

Moles emphasises that the 'costs' of breakdown and repair are not just economic, rather, the overall costs of repair impinge on the life projects of users when objects need repairing; and for some consumers those life projects will be further disrupted if the focus shifts from repair in general to self-repair. He continues,

> *...owing to the disturbance of the consumer‘s normal flow of life (through the object‘s unexpected disappearance), the telephone expenses, the costs of various errands, and the cognitive cost of putting one‘s trust in the merchant, the repairer, and the installer, the effective personal costs of problems arising in any object of the environment can seem enormous in relation to the commercial value of the object itself, (1985, p. 58-59).*

The right to self-repair would seem to be a solution; no travelling, spare parts, tools and instructions made available, etc. However, self-repair does nothing to address Moles' claim that “People are [therefore] provisionally forced by the objects they own to repair them or find substitutes for them, consequently to take some sort of action, thus incurring another general cost” (1985, p. 56).

Self-repair in Moles' view becomes a form of material self-administration in an era in which it is not just material barriers that discourage self-repair but in which attention is spread thinner, cognitive demands are increasing and motor skills are declining.

According to Moles a ‘comprehensive guarantee’ would aim to cover the ‘minimal general cost of breakdown’ of an object. As such, it would work strongly against poor product durability. This is because the guarantee covers the provision of ‘mobile repair squads, collection, repair and delivery of the defective object, replacement of defective parts, coverage of the labour required to repair the object, a guarantee of replacement with an identical object to compensate for the loss of the object‘s use, payment of the consumer‘s "price for time" for disturbance of the individual‘s "life project", and full guarantee of preventative maintenance for a duration known as the "insured period of life" of the article‘ (Moles, 1985: 56 *passim*). Manufacturers would have no reason to plan obsolescence. Instead, it would be in their interests to ensure durability in order to prevent consumers using the guarantee. Instead, Moles speculates that producers may compete around these compensation strategies rather than around price. Moles' approach radically extends producer liability and reconciles the material and abstract barriers to self-repair.

Moles conceives of two repair realms. The first, covered by the comprehensive guarantee, places liability for collection, repair, return, parts and ongoing preventative maintenance onto producers; it cannot be offloaded to either third parties or consumers. It also includes liability for disturbance of consumers' 'life projects' arising from broken products. At the end of the guarantee period goods pass into a secondary status which would be the realm of self-repair with costs and responsibility passing to the user. This is where both creative and practical self-repair could be most effectively defended and extended.

## Conclusions

People are more than just consumers of products. They have unique 'life projects' and by no means all will be oriented to the concerns of PLATE. The comprehensive guarantee recognises this and accommodates it without rancour while still valuing repair as a social practice. The right to repair does not offer the same accommodation. No one is likely to be against repair as the 'stuff of common sense' in principle. However, should my phone, computer or washing machine need mending I know which option from the 'right to repair' or a comprehensive guarantee appeals to me. What practical wisdom I have I would sooner devote to more rewarding ends than mending broken consumer goods.

# Identifying barriers and enablers for circular ICT practices: An exploratory study

**Kathleen McMahon[a], Erik Jan Hultink[a], Ruth Mugge[a]**
a) TU Delft, Faculty of Industrial Design Engineering, Department of Design, Organization, and Strategy, Delft, The Netherlands

**Keywords**: Lifetime Extension; Circular Economy; Decision-Making; Information and Communications Technology (ICT); Electrical and Electronic Equipment.

**Abstract**: Information and communications technology (ICT) equipment plays an important role in the global transition to a circular economy due to its share in electronic waste generation and its composition of both hazardous and valuable materials. Organizations have the potential to make significant impacts on these transitions due to large amounts of ICT equipment under their care. While research into challenges faced by businesses transitioning toward circularity is growing, information on what factors prevent this transition for the ICT sector is limited. In this research we aim to identify what influences decision-making for incorporating circular practices in procurement, maintenance, repair, and disposal of ICT equipment within organizations. We conducted 10 in-depth interviews across four organizations with individuals involved in all stages of decision-making for ICT equipment in order to identify barriers to making decisions that increase ICT related circularity. Through analysis of the transcribed and coded interviews, we identified 16 barriers to incorporating circular ICT practices in the decision-making processes of interviewees and their organizations. We present actionable, ICT specific areas of focus for organizations to increase their ability to enact circular improvements. Specifically, we identified barriers relating to five themes: limitations to suitable and timely ICT equipment, lack of awareness and knowledge about circular ICT, limitations to individual and organizational decision-making about circularity in ICT, limitations based on ICT contracts, supports, and security, and financial and other cost factors for circular ICT. Based on these barriers, we suggest a set of characteristics for a successful transition to more circular ICT in organizations.

## Introduction

A shift from the current status quo to a more circular economy is in heavy focus in the European Union (EU) and of pertinent importance for global legislation [1]. This is particularly true for electronic equipment due to its hazardous nature as waste and its composition of valuable and difficult to obtain raw materials[2] (Baldé et al. 2022). Given that the waste categories that include information and communications technology (ICT) equipment accounted for more than 20% of global e-waste generation in 2019, ICT will play a particularly important role in this sustainability transition (Forti et al. 2020).

Commercial and public entities are responsible for large collections of ICT equipment. Due to this important role, organizations have the potential to make significant impacts to circularity through the prevention of ICT waste. However, today's organizations tend to follow linear processes, resulting in premature disposal of ICT equipment. Lifetime extension of this equipment can provide many environmental benefits for ICT products, e.g., laptops, data servers, etc. (Bakker and Schuit 2017; Den Hollander et al. 2017).

Current studies suggest that the implementation of circular practices, such as reuse and other lifetime extension activities, has presented challenges for organizations (Hina et al. 2021). These extant studies present these barriers as both internal, including financial, structural, attitudinal, and barriers relating to knowledge and technology, as well as external, relating to supply chains, legislation, and governmental support (Ritzén and Sandström 2017; de Mattos and de

[1] https://environment.ec.europa.eu/strategy/circular-economy-action-plan_en

[2] https://environment.ec.europa.eu/topics/waste-and-recycling/waste-electrical-and-electronic-equipment-weee_en

Albequerque 2018; de Jesus and Mendoça 2018; Vermunt et al. 2019). Guldmann and Huulgaard (2019) suggested that most barriers to circular business model innovation exist at the organizational level, and Klein et al. (2020) found that research on barriers for the public sector focuses largely on procurement related processes. These studies mostly examine barriers relating to general circular economy and circular business model innovation, while insights on industry specific ICT barriers and enablers are limited. However, in terms of ICT, a notable exception found that value chains and collaboration have been identified as important factors in increasing lifetime extension through reuse of ICT by 'gap exploiters'. These organizations are established to fill existing gaps in lifetime extending opportunities, such as refurbishing (Whalen et al. 2017).

Due to the limited presence of ICT specific, actionable information on what might enable organizations to better incorporate circular ICT practices, the study presented in this paper aims to explore what factors cause organizations' difficulty in transitioning from linear to circular decision-making about their ICT equipment. In particular, our study explores which factors influence decisions made about procurement, maintenance, repair, and disposal practices that affect the first use and overall lifetime of their ICT equipment, and thus, how to approach encouraging critical behavioral change and acceptance of more circular ICT practices.

## Methods

### *Interviews*

Interviewed organizations were selected from a pool of project participants and through further snowball sampling. Interviewees were nominated within organizations based on job proximity to ICT procurement, maintenance, and disposal processes. A total of 10 in-depth 60 to 90-minute interviews across four organizations were conducted with decision-makers from different functional backgrounds. Interviews were adapted to ICT specific issues based on common barrier themes found in existing literature on circular transitions. Namely, these included the internal and external barrier themes presented in Hina et al. (2021) such as company policies and strategies, finances, lack of resources, supply chain concerns, collaboration, and legislative barriers.

### *Analysis*

All interviews were recorded in order to be transcribed. Interview transcripts were analyzed using Atlas.ti, where quotes could be coded. A thematic analysis of the interview transcripts produced 97 codes, verified through discussion within the research team. Within these codes, we identified 16 barriers, which, through discussion with the research team, were further grouped into five themes presented in the following section.

## Results

Grouping the analyzed barriers resulted in the establishment of five key themes relating to the challenges of an organization's incorporation of circularity into their daily practices, which are expanded in the following subsections. While many interviewees highlighted their organization's desire and efforts to improve their circularity, the presence of these barriers often limit their ability to do so.

### *Limitations in access to suitable and timely circular ICT equipment*

| **Barrier Codes** |
|---|
| Access to circular ICT devices and spare parts |
| Limitations to incorporating refurbished ICT equipment |

**Table 1. Barriers relating to accessing suitable and timely circular ICT equipment.**

The first theme relates to limitations in obtaining circular ICT devices within time frames that do not impact functional performance (Table 1). For already purchased ICT equipment, obtaining and storing spare parts for older models can also be difficult, which limits repair options.

Although interviewees expressed interest in procuring refurbished ICT equipment, they found that the immediate availability of refurbished equipment with the needed specifications is limited, due to dependence on incoming equipment, existing stocks, and processing time. There is also limited or no support contracts for refurbished ICT equipment, which further limits the ability of organizations to choose refurbished equipment.

### *Lack of awareness and knowledge about circular ICT*

| Barrier Codes |
|---|
| Lack of awareness about the benefits and importance of circularity in ICT |
| Lack of knowledge about and/or ideas for incorporating circularity in ICT |
| Limitations in the flow of ICT device related sustainability information |

**Table 2. Barriers relating to the awareness and knowledge needed to incorporate circular ICT practices in organizations.**

Awareness and knowledge were highlighted as important factors in making an organizational transition to circular practices (Table 2). However, interviewees felt that organizational decision-makers often lack the awareness of circularity's importance and benefits that is necessary to effectively initiate more circular ICT activities within the organization. Interviewees also reported that a lack of understanding of the benefits of ICT circularity and how circularity and other necessary processes fit together results in fewer, less effective circular initiatives at various employee levels.

Furthermore, both producers and purchasing organizations have information about devices (e.g., material content, energy consumption of production, etc.) that would benefit circular decision-making. However, interviewees stated that the parties often have difficulty passing this information to each other through the suppliers serving as a bridge between producer and purchaser.

### *Limitations to individual and organizational decision-making about circularity in ICT*

| Barrier Codes |
|---|
| Difficulties in assessing the true impact of differing circular ICT strategies and choices |
| Difficulty translating ideas for ICT circularity into concrete actions |
| Lack of accountability and initiative for circular ICT decisions |
| Prioritization of basic organizational and ICT equipment needs over circularity |
| Pressure from the product user based on their wants for and perspective on long lasting and circular ICT equipment |

**Table 3. Barriers relating to limits to individual or organization level decision-making about circularity in ICT.**

Even when awareness of the benefits of circularity is present, organizations still face a number of barriers that can impact whether a circular decision will or will not be made (Table 3). For instance, many organizations lack a person to take accountability for the decision to make a transition. Others find limited support or requirements from upper management to increase circularity in ICT. These were reported to result in less action.

Furthermore, interviewees find it difficult to implement (often vague) ideas into concrete actions for ICT equipment that have a real impact on circularity. In the words of one interviewee, "the tough part is translating the sort of high-level statements on circularity to very concrete things which impact individual departments (P2)."

A lack of previous baseline measurements, difficulties in knowing which ICT decision would make the most impact, frequently changing eco-standards, and potential misrepresentation of the actual circular impact of services (i.e., greenwashing) further contribute to confusion over what decision will have the biggest positive impact on circularity.

Beyond that, organizational needs often have greater priority than circularity or new circular initiatives, including changes in circumstances necessitating purchase of new or updated ICT equipment, energy costs, as well as a need for low-cost, reliable ICT equipment that meets performance goals, standardized orders and equipment, and support for existing/mature sustainability initiatives.

Lastly, the user of the device has preferences about what ICT device they want outside of the necessary specifications. These include wanting new and aesthetically pleasing devices, devices with performance capabilities higher than their needs, and devices of a familiar brand or model. One interviewee, referring to the perception of the average ICT user, stated that "we don't like change; we like new stuff; we don't like old stuff (P3)." Interviewees stated that users also often perceive personal ownership of the device, resulting in the push for their own preferences. These preferences often create premature ICT equipment turnover, shorten the lifetime of existing ICT equipment, which limits the circularity of the new equipment that is purchased.

### *Limitations based on ICT contracts, supports, and security*

| Barrier Codes |
|---|
| Limited supplier interest in lifetime extension |
| Existing or available contracts limiting circular choices |
| Concerns for data security in outdated or unsupported ICT equipment |

**Table 4. Barriers relating to ICT contracts, supports, and security.**

Interviewees noted that lifetime extension is often not in the ICT supplier's financial interest, which lowers supplier's participation in lifetime extending initiatives, especially when the organization does not express circularity as a priority. Resulting contracts have limited built-in circularity and shorter service-period lengths, after which ICT equipment that the organization may decide to keep longer would be unsupported and more difficult to maintain. Older and/or unsupported ICT equipment may also have outdated software and hardware security compliance, which risks data security and compliance, complicating lifetime extension.

At the end of life, maintaining the reusability and recyclability of ICT equipment is an important step in the transition to a circular economy. However, interviewees reported in some cases organizational hesitancy about the completeness of data wiping processes, leading to non-circular waste treatment activities (e.g., shredding hard drives).

### *Financial and other cost factors for circular ICT*

| Barrier Codes |
|---|
| Financial barriers to circular ICT |
| Costs and limits specifically to repair |
| Short lifecycle management (LCM) periods |

**Table 5. Barriers relating to financial and other cost factors of incorporating circular ICT practices.**

Financially, a number of factors affect the decision to transition ICT processes to longer lifetimes (Table 4), such as existing budgets that do not include circularity, the potential or perceived higher initial cost of circular equipment, and the cost of extending contracts for supported longer life equipment.

Repair was conducted at some level by most organizations. However, there are also different types of costs that affect the decision of whether or not to repair a device, including the necessary time and specialized tools to conduct the repair and the total cost of repair weighed against the current value of the ICT device. When these costs are considered too high, repair is not done, limiting the lifetime of the device.

From purchase to disposal, LCM helps organizations monitor assets in an efficient and cheaper way. However, LCM periods, which set a number of years a device should be used, can result in premature disposal of usable ICT equipment when the LCM period is over.

### *An 'ideal' scenario*

These reported barriers illustrate several paths forward for organizations to succeed in transitioning to a more ICT circular workplace. On one hand, interviewees suggested that organizations must make a number of structural adjustments in order to encourage accountability and initiative to create and enact circular ICT practices. Interviewee suggestions included dedicating a role within the organization specifically to sustainability as well as incorporating sustainability into each and every role. One interviewee emphasized the importance of this with the statement that "you just have to more and more convince people that it's part of their role as part of their DNA as well (P2)". From another angle, the importance of showing organizational initiatives was highlighted by another interviewee in terms of talent retention, stating, "we sometimes see that we even lose [people] because they want to dedicate [a percent of] their roles to sustainability (P2)". A common method suggested by interviewees as an enabler for increasing accountability and initiative and incorporating circularity into employee roles was the introduction and use of targets and incentives. As an illustration of the potential success of such initiatives, one interviewee indicated that in the first year of an incentive program tied to decreased emissions the employees have nearly maxed out the possible pay-out. Organizational targets and the pressure to report improvements set by the legislature or influenced by political or public pressure were also suggested to enable circularity incorporation. This is highlighted in interviewee statements such as "it would help us a lot to be challenged... we need to somehow share what we have accomplished (P6)" and "the pressure to report on these kinds of sustainability aspects is now very high again (P8)." These external pressures place responsibility on high ranking, influential decision-makers by "[making] the director responsible for sustainability and [he or she] would be measured on that at the end of the period (P1)."

On the other hand, improved access to information about circularity for ICT and the communication of that information is indicated as a key factor in the future success of organizations' circular transitions. Interviewees expressed an interest in obtaining factual, representative, and comparable information on the true impact of a circular ICT choice over a traditional linear choice, or of one circular ICT choice over another. Interviewees were further asked to specify what types of information would be beneficial to their decision-making when provided in a tool such as, for instance, a digital product passport. Digital product passports (DPPs) have become increasingly topical as a tool to contain material, use, and reuse, supply chain, and other data about an individual device in one accessible place and have been incorporated into several recent proposals by the European Commission. To contribute to this development through our research, Table 6 shows a list of information types for such a digital ICT product passport that interviewees expressed interest in obtaining to better understand and implement solutions to circular ICT needs.

| Types of Circular ICT Device Information |
|---|
| • Realistic expected product lifetimes |
| • Energy consumption in production |
| • Energy consumption in the use phase |
| • Recycled material content |
| • Information on financial costs and toward of equipment with a high circularity standard |
| • Repair and performance history (device tracking) |
| • Accurate recyclability of the device and components (including actual returns with current technology) |
| • A comparative assessment of circular impact of different choices and devices |

**Table 6. Examples of specific information types that would benefit organizations in a digital product passport.**

The combination of these structural changes in employee roles and responsibilities and improved spread and absorption of information would also enable better communication and negotiation with suppliers for the inclusion of impactful circular choices. Interviewees stressed the importance of communicating clearly to suppliers that circularity was a top priority for their organizations.

## Conclusions

This study presented important and timely empirical evidence about what factors prevent organizational decision-makers from incorporating ICT circularity into their daily business. These insights provide a useful set of actionable recommendations for what organizations may do, or not do, to facilitate their transition from linear to circular ICT practices. These results will be further helpful in the development of ICT specific tools for improved circularity, such as product passports.

## Acknowledgments

The authors of this paper would like to thank the consortium partners of the RePlanIT. Funding for this study was provided by the Rijksdienst voor Ondernemend Nederland, TSE Industry 2021: Circular Economy.

# The Circular Techno-Aesthetics of Woven Textile-forms: A Material and Process-driven Design Exploration

**Holly McQuillan[a], Milou Voorwinden[a, b], Bente Arts[a], and Barbara Vroom[a]**
a) Delft University of Technology, Delft, Netherlands
b) Studio Milou Voorwinden, Amersfoort, Netherlands

**Keywords**: Sustainable fashion and textiles; 3D weaving; Material-driven design; Multimorphic textile-form; Circular techno-aesthetics.

**Abstract**: Material-Driven Design (MDD) proposes that we value the behaviours, performance properties, and aesthetics that emerge from a material's inherent properties – an approach that provides a much-needed perspective for the textile and fashion industry as it develops new sustainable and circular systems. This research expands this material-led approach to include design-production processes framed within holistic notions of sustainability. In contrast to a conventional top-down design research process, material-processual-driven design approaches may enable us to break from the trap of developing and evaluating the outcomes of new design systems through the lens of our existing (usually unsustainable) approaches. This paper reflects on the tensions experienced by the authors in navigating concerns of technological feasibility, aesthetic outcomes, and the sustainable goals framing two sets of woven textile-form design experiments. Textile-forms are design-production processes that emerge from the simultaneous production of textile and form via the interlacement of matter/fibre/yarn and are designed to facilitate localised, on-demand production of textile-based objects. We will present the experiments, which were developed over six months, reflecting on the technical and evaluation processes that contributed to their development and the challenges that arose. This paper provides grounded examples of design researchers navigating this challenging space and the outcomes that emerge and aims to contribute to a greater understanding of circular techno-aesthetics that may support the industry as it develops the new systems it needs.

## Introduction

The majority of garments look the way they do because of a complex interaction of social, cultural, economic, and technological factors. Everything from spinning technology, loom design, the technical requirements of fabric cutting equipment, the division of labour to facilitate mass production, and the expectation that we can extract and waste vast quantities of raw materials and exploit people in repetitive and/or dangerous working conditions, all contribute to the aesthetics of the garments we wear every day. Now, both ordinary citizens and the industry's understanding of evaluation criteria for textile and garment performance and aesthetics are based on technological development focused on uniformity, ease and speed and low-cost production. Decades of building and then operating within this deeply problematic paradigm have created a landscape and regime (Geels, 2011) with a set of processes and expectations - for both industry and users - that seems difficult to deviate from.

This paper presents two woven textile-form (WTf) design cases that take a user or material-centred research through design (RtD) (Stappers & Giaccardi, 2017) approach while attempting to holistically address identified sustainability issues in the textile and garment industry. We argue that for the textile and fashion industry to transform in the manner and scale required, our technical, design, aesthetic processes, evaluation metrics and expectations need to be fundamentally redesigned. By reflecting on our experiences as designers attempting to navigate this complex space, we hope to provide insights that support a broader understanding of the transformation that is needed within the design discipline.

### *Sustainability in Fashion and Textiles.*

In the textile and fashion industry, efforts aimed at sustainability have emphasised increasing efficiency (e.g., Rissanen & McQuillan, 2016; Runnel, Raihan, Castle, Oja, & Bhuiya, 2017), the replacement of problematic materials (de

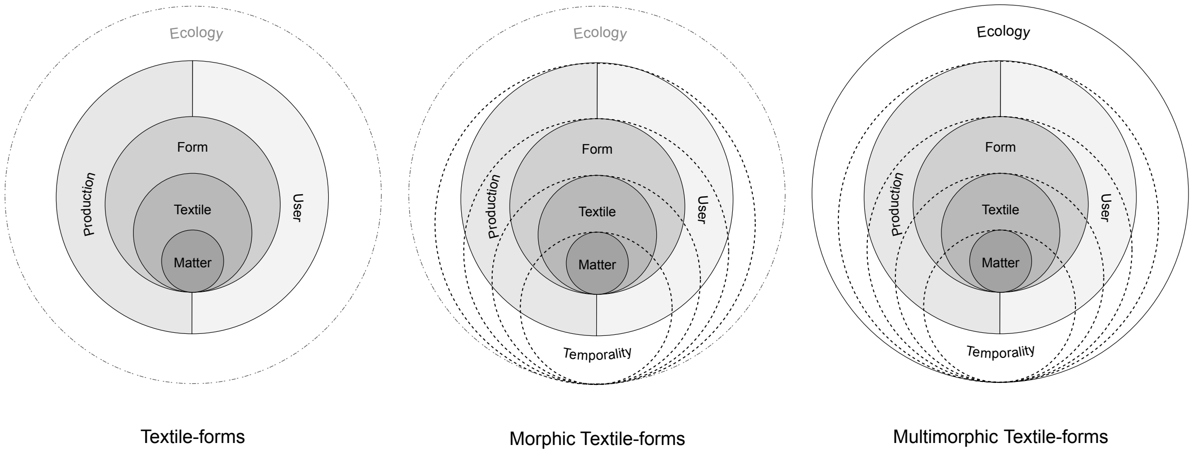

**Figure 1. Model for Textile-form, Morphic Textile-form and Multimorphic Textile-form showing the relationship between all common elements (Textile-forms: Matter, Textile, Form, Production and User), and the differences when temporality (Morphic Textile-forms) and ecology (Multimorphic Textile-forms) are emphasised. Adapted from McQuillan & Karana (2023).**

Oliveira Neto, Correia, Silva, de Oliveira Sanches, & Lucato, 2019), an emphasis on consumer responsibility (Shen, Wang, Lo, & Shum, 2012) and circularity (Rathinamoorthy, 2019). Increasingly we see policy levers imposed on the textile and fashion industry (e.g., "Dutch Policy Programme: Circular Textiles 2020-2025," 2020; Juanga-Labayen, Labayen, & Yuan, 2022). Systemic over-production of fibre, yarn, textiles, and garments is a major contributing factor to the industry's climate impact (Niinimäki et al., 2020; Sandin, Roos, Spak, Zamani, & Peters, 2019).

### *Textile-Form Design and Production.*

The most used textile methods, weaving and knitting, usually make 2D fabrics for cut and sewing into 3D form. This multi-step process divides textile and form production across multiple locations, contributing to exploitation, overproduction and carbon emissions (Sandin et al., 2019). In contrast, textile-forms emerge directly from the interaction of molecules, fibres, yarns, textile structures and finishing processes, into 3D form such as garments (Peterson, 2020), products (Albaugh, Hudson, & Yao, 2019), or even architecture (Popescu et al., 2021). They move closer to or achieve, additive and automated manufacturing processes, eliminating much of the manual labour in garment production, enabling localised, affordable garment on-demand production, therefore reducing overproduction. The most well-known example of a textile-form method is 3D knitting, or WholeGarment™ knitting, where a knitted object emerges directly from the knitting machine, with little waste or post-knitting processing required. Other less-known methods are 3D printing ("Kinematics Dress 6," 2016), moulding (Hoitink, 2016), weaving (Walters, 2021), and growing textile-form in the context of bio-design (Zhou, Barati, Wu, Scherer, & Karana, 2021).

The focus of this research is Woven Textile-forms (WTf) which makes 3D form by interlacing warp and weft yarn on a loom. Outside of hand-woven shaped woven garments (e.g, Piper, 2019; Wagner et al., 2022), industrially woven examples include: those woven on digital jacquard looms (Buso, McQuillan, Jansen, & Karana, 2022; Lucchi, 2018; Miyake & Fujiwara, 1999); 3D looms (Harvey et al., 2019; Shi, Taylor, Cheung, & Sayem, 2022); and the use of novel looms developed specifically for this purpose (Zorthian, 2021). Compared with knitting, there is significantly less research and development for weaving form. Loom development has focused on the production of 2D fabric for the cut-and-sew garment industry, and there has been limited development of infrastructure or digital design tools for WTf (an exception is Wu et al., 2020). The existing technological system, and related industry and societal expectations, have profound impacts on the acceptance and potential uptake of WTf. However, WTfs relative newness provides an opportunity to forefront sustainability in its development. In this paper we focus on this complex intersection.

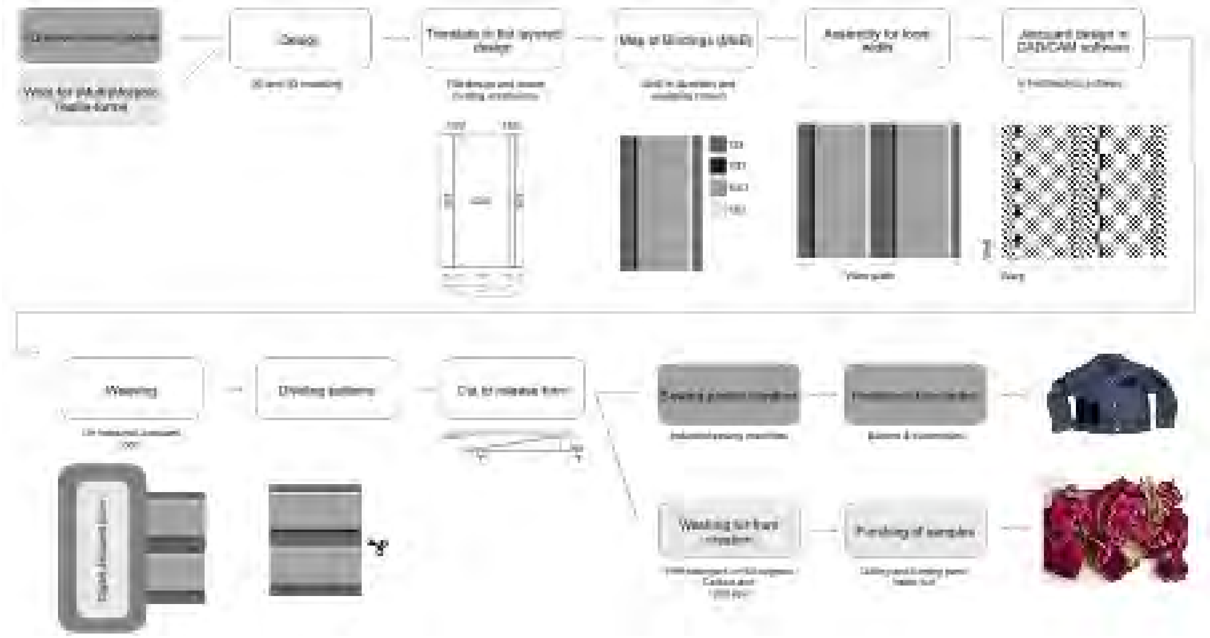

**Figure 2. Overview of the application of Woven Textile-form production in the conventional textile industry production chain specified for both 3DWDJ and W4MTF, addressing design, programming, production, and finishing.**

## Our Approach

When a holistic view of sustainability is applied to the development of WTf then design and production consider change over time across material, use and ecological scales - Multimorphic Textile-forms (Fig. 1) (McQuillan, 2020; McQuillan & Karana, 2023). This approach goes beyond the reimagining of the processes which make textile-based form, and into new material relations and aesthetics. This research uses RtD develop outcomes that help build on Material-Driven Design (MDD) (Karana, Barati, Rognoli, & Zeeuw van der Laan, 2015) to include process-driven design approaches (designing and weaving textile-forms) and aims to contribute to sustainable transitions for the fashion and textile industry (Buchel, Hebinck, Lavanga, & Loorbach, 2022).

We build on emerging discourse for MMTF by providing two contrasting cases that deepen our understanding of the application of this method (Fig. 2) in the industry and the ways in which users may respond. The 3D Woven Denim Jacket (3DWDJ) was developed with a user-centred lens, aiming to maintain as much of the look and feel of existing denim jackets to support user acceptance. A small user study was conducted to understand how users responded to the aesthetics and material experience that result from the novel production process. Wool for (Multi)morphic Textile-forms (W4MTF) used MDD to develop textile-forms using wool as a shape-changing material. The aim was to discover novel material expressions from a mono-material, and used the materials experience framework (Camera & Karana, 2018; Giaccardi & Karana, 2015) to understand the unique material experiences provided by wool's inherent properties in the context of WTf.

To unpack this complex and interconnected negotiation between the existing regime within fashion and textiles, and the emerging design and technological niche practices of MMTF, next we present two design cases, discussing the challenges and evaluation processes that contributed to their development.

## Woven Textile-forms - Design Cases

### *3D Woven Denim Jacket*

The 3D Woven Denim Jacket (3DWDJ) project sought to redesign the construction of a conventional denim jacket (Fig. 3, top) by using WTf design methods to reduce waste and production steps during the construction of a denim jacket while retaining the existing emotional and physical durability users expect. An analysis of denim jackets' cultural meaning with existing wearers and existing construction methods, led to design requirements (see Table

1) that aimed to maintain the features that are commonly associated with denim jackets.

**Figure 3. Top: Levi's Type 3 Trucker Jacket is a classic example of a conventionally constructed denim jacket. Bottom: V.1 of the 3DWDJ for comparison.**

Using these design guidelines, three versions were developed from a single WTf concept to explore different design variables (Table 1). All were woven on a digital jacquard loom in a vertically integrated factory in Pakistan (Fig. 4). V.1 (Fig. 3, bottom) focuses on minimising finishing processes, and so has only 5 sewing steps (compared to the usual 29) by leaving all edges raw. V.2 explores a higher level of finish by using conventional finishing processes in combination with 3D weaving to finish all of the edges. V.3 is a zero-waste version of V.1, achieved by overlapping the pattern pieces. See Table 1 for a summary of all three.

V.1 was presented to the initial denim jacket user group that contributed to the design guidelines, and additionally to three denim jacket users without prior knowledge of the project. All described V.1 as being in the category of a denim jacket, while also recognizing some differences (which were all material expressions of the process used, see Table 1) from a denim jacket as they know it.

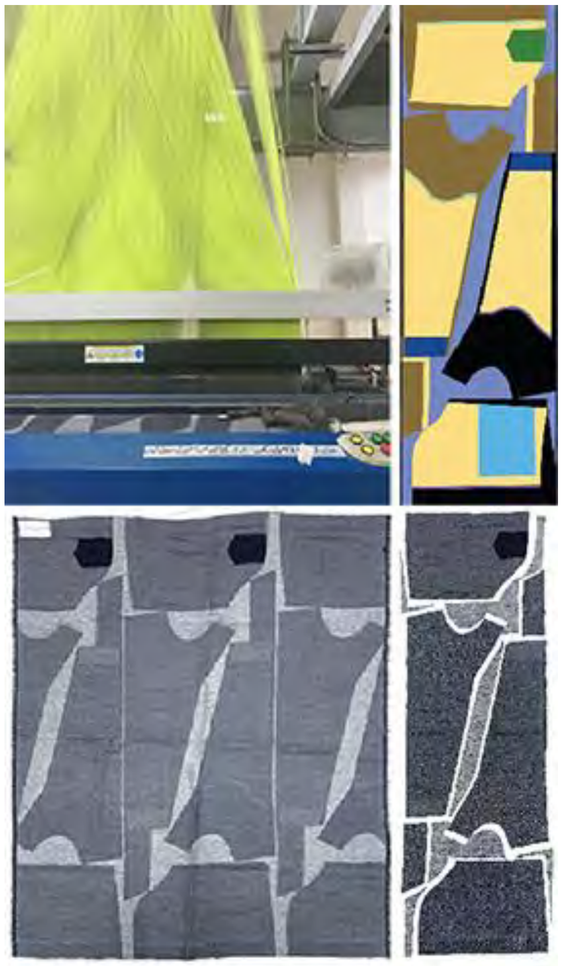

**Figure 4. Top left to right: Digital jacquard loom used to weave all the 3DWDJ samples, The MoB for V.1 which is programmed with 3D weave structures. Bottom left to right: Loom state of V.1, and a single jacket panel after cutting – the light areas of textiles are waste.**

| | | Overall | V.1 | V.2 | V.3 |
|---|---|---|---|---|---|
| Design requirements /aim | | The design should maintain the 'essence' of a classic denim jacket and fulfil a similar role in the user's wardrobe. The fabric structure, colour and material experience should be consistent with what is expected of denim fabric. The form should have a boxy fit with a well-fitting sleeve-to-body relation, and a front waistline that is longer than the back, with a collar and strong front placket for hardware. |  Minimise post-weaving sewing steps to support automation. |  V1 but with a finish more consistent with existing denim jackets. |  V1 adapted for zero waste layout |
| Technical/ Production | Loom | Digital jacquard loom, air jet weft insertion. 144.3 cm wide, 40.3 ends/cm, One full centre repeat (59.5 cm) in the centre and two partial repeats on either side (42.4 cm). | Most areas are 1 or 2 layers. 3 layer areas (such as pockets) are woven using 1/4 of warp and weft to maintain the structural integrity of the overall form. The unusual (uneven) repeat arrangement significantly impacted the form design/layout and the resulting waste as a proportion of fabric width. | | |
| | Material | *Warp yarn:* (Ne20) Indigo dyed cotton *Weft yarn:* 50 picks/cm Ne8 60% Hemp, 40% cotton. 2 indigo, 2 white | To maintain an overall denim look with an indigo surface and a white back of the fabric, two blue and two white weft yarns were used. | | |
| | Textile | *Structure:* Warp-faced twill variations, 3D woven, mostly limited to 2 layers. *Finishing:* Uncut cloth was singed, resized and sanforized | *Structure:* Structures were locally programmed to ensure even overall density and consistent indigo surface appearance. | | |
| | Form | *Construction:* Minimise sewing steps and complexity. *Seams and edges:* Seam strength is comparable to, or stronger than cut and sewn denim seams. Weave structures and pattern pieces are designed to reduce fraying as much as possible. Woven seams areon the outside of the jacket, while sewn seams were internally constructed. *Cutting:* All cut lines should be on the outside to facilitate CNC cutting processes at a later date. Separate pattern pieces can be cut in multi-ply lays, but any multilayer, overlapping structures have internal cut lines that must be cut in single lays. | *Pattern:* 6 pattern pieces: *Cutting:* 6 pieces can be cut in multi-ply lays. 5 internal cut lines. *Edges:* Cut edges were left raw. *Construction:* 5 sewing steps | *Pattern:* 5 pattern pieces modified to utilise 3D weaving methods for finishing edges. *Cutting:* 5 pieces can be cut in multi-ply lays. 10 internal cut lines. *Edges:* All edges are finished. *Construction:* 9 sewing steps. | *Pattern:* 6 pattern pieces overlapped to eliminate waste. *Cutting:* 1 cut line can be multi-ply lay. All remaining cuts are internal. *Edges:* Cut edges were left raw. *Construction:* 5 sewing steps |
| Sustainability | | *Supply chain:* Textile and form are simultaneously produced. Automation supports personalised, local and/or on-demand production. *Supply chain challenge:* single-ply cuts limit mass production potential. *Waste:* Aim for reduction. Calculations for waste were based on the weight of panels rather than the surface area of the fabric or the width of the repeat. *Manual labour:* Automation leads to a reduction in manual labour. | *Supply chain:* Single-ply cuts limit mass production potential. *Total material weight:* 514g *Waste:* 14% *Manual labour:* Most automated | *Supply chain:* Single-ply cuts limit mass production potential. *Total material weight:* 490g *Waste:* 15,5% *Manual labour:* Least automated. | *Supply chain:* Single-ply cuts significantly limit mass production potential. *Total material weight:* 340g *Waste:* 1,16 %. *Manual labour:* Cutting may require more manual labour than V1. |
| User study | | Users reported its lighter weight, variable surface structures, external woven seams and fraying edges, as differences from a standard denim jacket. The participants did not report the differences as 'bad', but rather as something 'cool' and raw, like a denim jacket as they know it. | | | |

**Table 1. An overview of 3D Woven Denim Jacket design requirements, technical, production, sustainability, and user findings.**

*Wool for (Multi)morphic Textile-forms: Exploring Novel Material Experiences.*

Wool for (Multi)morphic Textile-forms explored novel material expressions merging from the inherent properties of wool (that it can shrink and felt - a behaviour that the textile industry often seeks to suppress) when manipulated in WTf to challenge conventional expectations and processes for textile objects. MDD facilitates the emergence of material expressions from the inherent properties of the hybrid material-process and supports holistic perspectives when designing for sustainable transitions.

W4MTF integrated temporality as a design variable with WTfs to enable shape-change in the production or use phase using wool. An understanding of the shape-change process was established by tuning the felting process via the density and layer arrangement of wool yarns in multi-layered weave binding constructions, as well as the use of washing-moulds to manipulate the final shrunken form. The various methods used (Table 2) sought changes in scale, form, texture, and firmness, creating atypical aesthetics and expressions (Fig. 5, bottom). Framed as an exploration of circular design focused on biological nutrients, ideally, both the warp and weft would be wool to make the outcomes a monomaterial, but limited loom availability meant that a loom with a polyester warp was used for sampling.

Participants interacted with the outcomes of the experiments in an experiential characterization (Camera & Karana, 2018) user study (Fig. 5, middle right, and Table 2), and validated the apparent coherent aesthetic expression - which are the material traces (Robbins, Giaccardi, & Karana, 2016; Rosner, Ikemiya, Kim, & Koch, 2013) of the processes used - which differs significantly from the textile aesthetics of existing industrial processes.

**Figure 5. Top Left to Right: Weaving samples on industrial jacquard loom. Samples of the loom separated by cutting. Middle left to right: Samples after the felting process, displaying changes. Participants conducting the experiential characterization user study. Bottom: Detail of Ex. 1 sample.**

**Table 2. Overview of Wool for (Multi)Morphic Textile-form experiments. The technical or process variables, aims of the experiment, how the experiment sample changed, and the resulting experiential characterization outcomes demonstrate novel material experiences possible with this material-driven design approach to morphic textile-forms.**

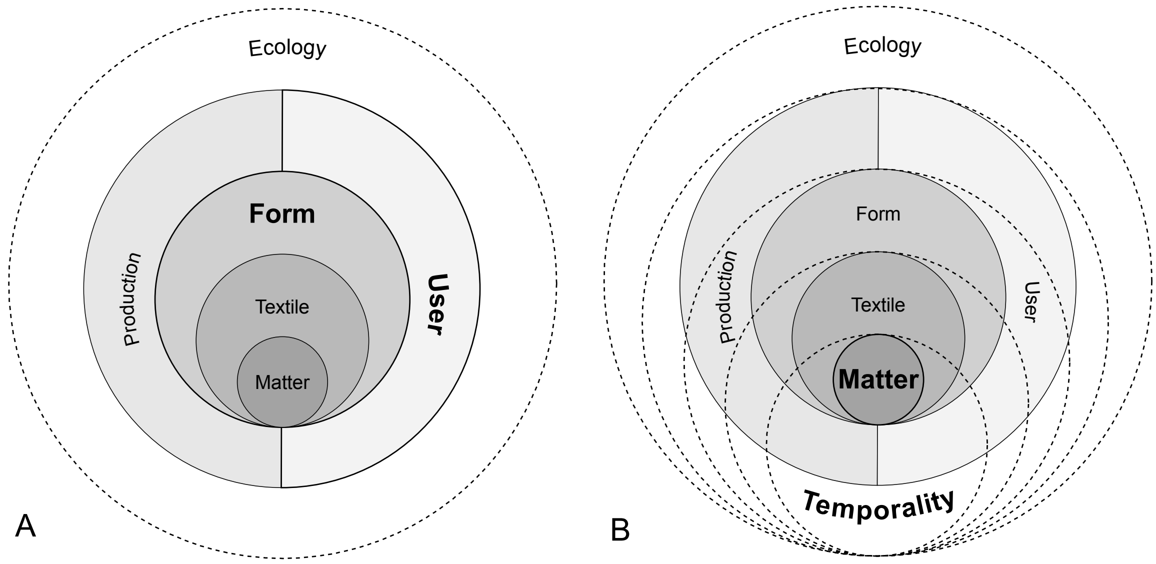

**Figure 6: For both cases, matter, textile, form, production, user, and ecology all need to be holistically attended to. However, the lens for the development of 3DWDJ (A) was in the form outcome (a denim jacket) for users (and their expectations). W4MTF (B), focuses on material, and temporality across all scales. Figure developed from McQuillan and Karana (2023).**

## Discussion

The cases both use a material-process driven design approach to explore the development of novel WTf's, however, their differences provide opportunities for reflection in the context of sustainable transitions. Where 3DWDJ (Fig. 6 A) aims to rethink the existing production opportunities, W4MWTF (Fig. 6 B) rethinks how we design and evaluate the outcomes of new material-driven design-production systems. Both design cases reveal the opportunities that such niche practices present designers, users, and industry, while simultaneously unveiling the power the existing paradigm has over designers, industry, and users - and the challenges that arise from this.

### *The Opportunities and Challenges of Woven Textile-forms.*

The textile industry can transition to a more sustainable process by utilizing technology, such as industrial weaving looms, and developing new models of design and production that reduce water and material waste, localise, and decarbonise production. WTf's, for example, can increase durability via the integrated woven seams (as was found during strength testing for the 3DWDJ), or locally tune weave structures to reinforce areas that experience increased wear. Furthermore, W4MTF demonstrates that designers can locally tune material properties such as density, cushioning, size or shape, and this can be activated during design or use-time – further enriching material/product experiences. These properties can be generated using mono-materials, reducing the need to use textile composites which are difficult to recycle. Furthermore, 3D weaving facilitates zero-waste production by enabling the overlapping of pattern pieces, while also utilizing fewer materials for the same garment unit (see Table 1, V.3).

The unique design-production process leaves material traces on the textile-form and create novel Circular Techno-Aesthetics (CTA) (developed from Simondon, 2012). The user responses from both design cases suggest that when an outcome communicates its origin and performance and gives meaning to humans, users may embrace new design aesthetics which emerge from circular design-production approaches. Their CTA could become a unique selling point for consumers.

Many of the challenges facing this niche practice stem from the industry's ongoing focus on rapid, uniform, and low-cost production of 2D fabric - for the cut and sew industry. While these WTf's can be produced on any digital jacquard loom, a high warp density with no repeat in the jacquard is preferred to allow for more design flexibility. However, only a few companies have looms suitable for this type of production, and they must be willing to provide their production facilities for research. Therefore, when using non-ideal looms, designers must make technical, material, aesthetic, and/or sustainability compromises. 3DWDJ for example encountered limitations caused by the unusual repeat size of the available loom - which impacted the form design and waste produced. While the lack of available jacquard looms with a wool warp meant it wasn't possible to create mono-material outcomes in W4MTF. Additionally, the production of WTf's requires a fundamentally different approach which imposes limits to the scale of production, particularly regarding the cutting of garments pieces in multi-ply lays (see Table 1). The appeal of scalable technology is powerful under the current industrial paradigm, but researchers and emerging brands must develop and prototype alternative models that resist growth, and reduce material use and emissions, while extending product lifetimes. These are perspectives which are fundamentally disruptive to the industry, and so likely to be resisted.

Another challenge facing the adoption of these approaches in the industry is the lack of educational resources and technological support. While the composition of our research team covered a wide range of experience with WTf, user and material-centred design methods, and programming for industrial jacquard looms - many of the insights from the design process were gained due to these differences in knowledge and background. Fashion and textile designers often have little knowledge of the technical details of each other's fields; therefore, new skill sets and shared vocabularies are needed. While such knowledge gaps can be supported by digital tools, there are few available for WTf. Furthermore, the complexity of the process and competing requirements require both knowledge and compromise. The comparative evaluation of outcomes can be challenging. While efficiency in woven materials is typically measured as a function of surface area, measuring efficiency in 3D knitting is more aligned - measuring the weight of the yarn - such an approach will be necessary when conducting a comparative LCA. From a designer's perspective, the novelty of the approach, and a desire to mimic existing processes/aesthetics (e.g., faithfully recreating a denim jacket) pulls focus toward the limitations of the processes. For example, W4MTF the material consistency/uniformity standardised in industry isn't possible or desirable but was still a challenge for the designer to accept – we anticipate that challenging such expectations for many designers, industry stakeholders and users will be difficult.

There is a clear need for research to develop alternative evaluation methods that align with sustainable transition goals. Furthermore, a common vocabulary will enable communication between researchers, brands, technicians, and designers. Also, design and pedagogical tools need to be developed to support designers and students working in these novel and complex spaces, and infrastructure must be developed through the lens of sustainable transitions to support these ways of making.

## The Circular Techno-aesthetics of (Multimorphic) Woven Textile-forms

To realise the potential opportunities of WTf, open questions relating to infrastructure, technology, education, design, evaluation, and user expectations need to be addressed in future research. The gap between theory and practice in sustainability is often critiqued (e.g., de Wit, Verstraeten-Jochemsen, Hoogzaad, & Kubbinga, 2019; Remy, Gegenbauer, & Huang, 2015). In the textile industry sustainability is commonly framed within transparency, material replacement, or evaluation processes for existing product domains. Multimorphic Textile-forms bridge theory and practice by embedding holistic sustainability as part of a design process that generates unique Circular Techno-Aesthetics that result from the material-process driven design approach. While presented as an opportunity, CTA also presents significant challenges for designers, the industry, and users.

For designers, CTA suggests the need to question current design evaluation methods for textile-based products (such as developing an outcome of a novel design-production process by embracing the CTA that may emerge, rather than using the lens of existing and familiar product expectations). While material and process-driven design approaches may enable us to break from the trap of developing and evaluating the outcomes of new design systems through the lens of our existing (usually unsustainable) approaches, most designers are familiar with top-down design research processes that address product or user needs. For users, when it comes to textile products, consumers have clear existing expectations. Denim, for instance, is expected to be durable, have a unique aesthetic, and fit and feel a certain way. However, changing the production process of these garments to a material-process driven approach, could change how consumers experience these garments. However, this should not be assumed to be a negative outcome and may support changing perceptions and expectations of textiles and textile-based products, within sustainable transitions.

Material-driven design surfaces the inherent properties of materials to support designers to move beyond a top-down, problem-centric approach to the development of technological or anthropocentric solutions. In combination with holistic design-processes, such as WTf, it forms a material-process driven design approach combing sustainable production with an enriched user experience of materials, and in doing so, may extend product lifetimes.

b) Guilford Glazer Faculty of Business and Management; The Goldman Sonnenfeld School of Sustainability and Climate Change, Ben Gurion University of the Negev, Beer Sheva, Israel

**Keywords** :Sharing economy; Environmental impacts; Product service system (PSS); Collaborative consumption; Circular economy.

**Abstract**: Although the digital sharing economy is commonly thought to deliver environmental benefits through more efficient use of existing product stocks, whether this is the case is not yet well understood. To address this research gap we conduct an extensive review of peer reviewed publications and white papers, and compile a dataset covering 152 papers that report on the environmental impacts of the sharing economy. We differentiate between empirical and theoretical papers and focus on the 88 empirically-driven analyses. Consolidating the results, we find that sharing is not necessarily more environmental compared to conventional consumption. Our results suggest that goods sharing is generally associated with better environmental outcomes compared to sharing of accommodation or mobility, with ride-hailing emerging as particularly prone to negative environmental outcomes. Contrary to previous suggestions, we find that resource ownership structure (centralized vs. peer-to-peer) is not a good proxy for environmental performance. Instead, we argue that more attention should be given to some of the underlying causes for the sharing economy's mixed environmental impact including platform logistics and consumer choice. We conclude by highlighting remaining research gaps and offer guidance on how the sharing economy could be steered to more environmental paths.

## Introduction

Broad adoption of information and communication technologies (ICT) have facilitated the emergence and expansion of a digital sharing economy in which individuals can become producers in multi-sided markets and share their underutilized assets with peers (Botsman & Rogers, 2011; J. Schor, 2020; J. B. Schor & Vallas, 2021; Sundararajan, 2017). Though sharing of underutilized assets is not new, ICT has allowed sharing to expand beyond existing social networks of friends and family and turn into a market phenomenon proliferating into almost every domain of consumption (Belk, 2014; Curtis & Mont, 2020; Einav et al., 2016; Richards & Hamilton, 2018; J. Schor, 2014; Sundararajan, 2017).

The digital sharing economy is a broad and somewhat ambiguous concept encompassing a wide variety of activities and domains. At its core are consumers granting access to underutilized products. Frenken & Schor, (2017), define it as consumers granting each other temporary access to underutilized physical assets, while Hamari et al., (2016), focus on how technology simplifies the act of sharing physical and non-physical assets. According to Acquier et al., (2017), the sharing economy lies at the intersection of three foundational ideas: The ***access economy*** - designed to optimize the use of underutilized assets; The ***platform economy*** - supports decentralized exchange between peers through digital platforms; The ***community-based economy*** - facilitates non- hierarchical, and non- monetized exchange.

Many have argued that by severing the link between ownership and access, the sharing economy will herald a revolution, or at least a major disruption, to traditional consumption and production systems (Heinrichs, 2013; Sundararajan, 2017). Including Product Service

Systems (PSS: Tukker, 2015) under its broad definition, the digital Sharing economy is commonly thought to deliver environmental benefits through more efficient use of existing product stocks (Botsman & Rogers, 2011; Heinrichs, 2013; Mishra et al., 2019; Nijland & van Meerkerk, 2017). For example, a wedding dress is typically used only once, so if it were to serve more than one bride, demand for new dresses would decline.

While it may seem intuitive that sharing would be inherently more sustainable, sharing does not necessarily lower environmental impacts (Frenken & Schor, 2017; Iran & Schrader, 2017; Pouri, 2021; J. B. Schor & Vallas, 2021). For example, when a residential apartment is not only rented on Airbnb while the owner is away on a planned vacation, but instead converted into a full-time vacation unit, use intensity would decline rather than increase. Even when sharing does increase use intensity of resources, sharing might not lead to the expected environmental benefits due to several reasons. First, sharing might not displace the conventional product it is expected to replace, but rather undercut more environmentally friendly options. Second, operating sharing platforms might necessitate additional services with added environmental impacts. Finally, the cost savings offered by sharing platforms can affect users' general consumption patterns (a phenomenon often referred to as rebound effect). This illustrates that the potential environmental implications of sharing may not be as straightforward as they seem at first. But while environmental impacts of sharing have been studied for shared mobility proliferated to almost every domain, knowledge and evidence regarding its environmental impact is scattered across industries and disciplines. As a result, the environmental impacts of sharing are not yet well understood. Using a systematic literature review, our goal is to analyze the full existing body of work on the digital sharing economy, consolidate the empirical evidence on its environmental performance, and examine whether sharing indeed presents a more sustainable form of consumption and under which factors.

## Methods

To evaluate the environmental impacts associated with the digital sharing economy, we used a systematic literature review (Briner & Denyer, 2012) including published academic work, conference papers, and industry reports. Papers were retrieved in March 2022, from Web of Science and Google Scholar using the query below.

> *(("sharing economy" or "platform economy" or "collaborative economy" or Uber or Airbnb or Lyft or "ride hailing") and ("environmental impact" or "carbon emissions" or "greenhouse gas" or "sustainability" or "rebound effect"))*

After running the query, search results were downloaded as reference files. Duplicates were removed using Python code and the remaining results were screened, first at title and abstract level and then at full text level. See table 1 for a full inclusion and exclusion criteria.

After screening 1,429 unique papers retrieved we were left with 133 relevant papers. Finding all relevant papers within the digital Sharing economy is challenging for several reasons. First, as noted in the introduction, the sharing economy has an amorphic definition. Second, the wide range of initiatives which could potentially fall under the tent of the sharing economy, and third as papers don't always self identify as related to the sharing economy via title, keywords, or abstracts. Not wanting to miss important papers, we then supplemented our web search via backward snowballing, where the initial dataset is searched for further relevant papers, adding 19 key papers which were cited in several relevant papers (Wohlin, 2014). Overall, 152 papers comprise our final dataset and were included in our analysis. Of these, 88 represented empirical research papers.

*Research landscape*
To get a better sense of the research landscape we analyzed the papers according to different factors including platform domain: goods, accommodation and mobility, and publication type: empirical papers, literature review, theoretical papers, and book chapters.

*Environmental impacts of sharing and the factors which affect them*
In order to draw conclusions from the literature about the environmental impact of the sharing economy, we classified all empirical papers according to different factors which could potentially affect environmental outcomes. We considered factors which relate to the platform and its operations including the type of product shared (i.e., sharing domain), sharing model, product ownership structure, and platform size, alongside factors related to the research design including the methodological approach, type of impact examined (environmental impacts, or consumption changes from which environmental outcome could be assumed), and the scope of the analysis. *Table 2* presents a detailed description of all factors considered in our analysis.

Next, to address our main research question, we assigned an environmental impact score to empirical papers. Since the papers reviewed differed in terms of methodological approach, system boundaries, and the type of environmental impact reported, we first had to convert the reported results into a uniform index of environmental performance. To this end, our research team carefully reviewed all papers and manually assigned each with a score based on its reported findings regarding environmental impacts using a Likert scale. Scores ranged from 1- Positive environmental impacts, to 5-Negative environmental impacts. Note that we did not evaluate the scientific quality of the papers nor their methods, just the reported results. To illustrate, in a paper reporting environmental impacts, if all scenarios or impact categories reported improved outcomes, the paper received a score of 1 (Positive). If most scenarios or impact categories were positive, but some negative it received 2 (Mostly positive), whereas when scenarios or impact categories reported both positive and negative results the paper received a score of 3 (Mixed), and a similar approach was used for score 4 (Mostly Negative) and 5 (Negative).

## Results

*Research landscape*
A detailed breakdown of papers by the domain (i.e. the type of resource shared) and publication type is presented in Table 3. Goods sharing covers a wider range of resources among which are food sharing (N=3), apparel (N=3), and library of things (N=2), while in accommodations research is predominantly focused on Airbnb (N=10 out of 12 papers).

*The environmental impacts of digital sharing*
Analyzing all papers using the environmental impact score we assigned revealed conflicting results - while some papers reported that sharing is environmentally preferable to conventional consumption (39%), others reported the opposite (39%), and the remaining were either inconclusive (4%) or reported mixed results (18%). We therefore examined if and how different factors could help explain reported environmental impact.

Looking into factors related to the platform, we found that in contrast to theoretical speculations (Curtis & Lehner, 2019; Curtis & Mont, 2020), P2P platforms are not more environmentally friendly than platforms where ownership is centralized (see Figure 1.c). Examining other factors, we found that larger platforms (measured as a function of its monetary value) tend to be associated with worse environmental impacts compared to smaller ones (see Figure 1.d). This association was particularly evident in the largest platforms worth $1 billion or more such as Uber, Lyft and Airbnb, and suggests that smaller scale platforms tend to have better environmental performance. However, since the larger P2P platforms are more well studied than the smaller, less known ones, these findings may suffer from selection bias and should be validated in future research.

Examining environmental scores by the type of resource shard (i.e. domain), we found that goods sharing studies tend to report more favorable results compared to accommodations, with mobility displaying both positive and negative results (see Figure 1.a). Ride-hailing emerged as an exceptionally harmful category (Alemi et al., 2018; Clewlow & Mishra, 2017; Rayle et al., 2016; Schaller, 2018, 2021; Ward et al., 2021) (see Figure 1.b).

Research on goods sharing mostly found environmental benefits from increased use intensity of underutilized products (Kerdlap et al., 2021; Makov et al., 2020; Martin et al., 2019; Schneider et al., 2019; Wasserbaur et al., 2020), though some of these may be eroded as more intensive use may shorten product lifespan (Retamal, 2017; Schneider et al., 2019; Zamani et al., 2017). In addition, goods sharing often requires supportive logistic operations which may increase demand in other sectors, such as transportation and cleaning leading to problem shifting (Amasawa et al., 2020; Behrend, 2020; Johnson & Plepys, 2021; Kerdlap et al., 2021; Makov et al., 2020).

Within shared accommodations, three key findings emerged. First, leasing an entire apartment is more common than the more environmentally benign option of leasing a room in an otherwise occupied dwelling (DiNatale et al., 2018; Görög, 2020; Jaremen et al., 2020). Second, Airbnb might not displace hotel stays (Görög, 2020; Sainaghi & Baggio, 2020; Srovnalíková et al., 2020; Strømmen-Bakhtiar & Vinogradov, 2019; von der Heidt et al., 2019; Zervas et al., 2017), and third, shared accommodation may induce additional travel as lower prices allow users to take more frequent and longer vacations (Farronato & Fradkin, 2018; Tussyadiah & Pesonen, 2015). Taken together, these findings suggest that shared accommodation increases rather than reduces demand for lodging.

In shared mobility, it is important to distinguish between different types of vehicles (i.e. cars vs. bikes and scooters, collectively referred to as micro-mobility) and within cars to differentiate between car sharing, which allows users to gain access to a vehicle (e.g. car2go, Zipcar), and ride hailing, which allows users to travel to their destination in a car with a driver (e.g Uber, Lyft).

Despite the variation within the domain of shared mobility, several significant findings emerged. First, despite expectations, shared mobility does not necessarily reduce vehicle stocks (i.e. the number of vehicles used overall). Within micro mobility, for example, fierce competition between bike sharing platforms increased bicycle stocks overall (Chen et al., 2020; Luo et al., 2020; Ma et al., 2018). In cars, car sharing seems to reduce car ownership (Becker et al., 2018; Chapman et al., 2020; Clewlow, 2016; Mishra et al., 2019; Nijland & van Meerkerk, 2017), but most ride hailing papers reported no change or increased car ownership, driven in part by the economic incentive to work as ride hailing drivers (Clewlow & Mishra, 2017; Gong et al., 2017; Paundra et al., 2020; Rayle et al., 2016; Zhang & Zhang, 2018). Second, research on all forms of shared mobility indicates that shared mobility often displaces use of low emissions modes of transport such as walking and public transportation rather than single occupancy car rides (see, for example, research on car sharing (Jung & Koo, 2018), ride hailing (Afroj et al., 2019; Diao et al., 2021; Rayle et al., 2016; Schaller, 2018, 2021; Tirachini et al., 2020), and e-scooters (Aguilera-García et al., 2021; James et al., 2019). Third, like goods, shared mobility platforms often involve environmentally intensive supportive logistic operations, required, for example, to rebalance vehicles according to demand. In ride hailing, this redistribution comes in the form of dead-head miles, where drivers drive around to pick up passengers potentially doubling the distance traveled (Oviedo et al., 2020; Schaller, 2021; Tirachini et al., 2020). For micro-mobility, this means loading bikes or e-scooters onto trucks and redistributing the stocks, (see research on bicycle sharing (Ding et al., 2021; Sun & Ertz, 2021) and e-scooters (Severengiz et al., 2020)). Last, stock lifespan, and replenishing stock at end of its life also affect environmental outcomes. Stock with a shorter lifespan needs to be replaced more often, increasing production and subsequent environmental impacts. For example, a decrease in e-scooter lifetime from 2 years to 6 months due to decreased product durability could triple emissions per passenger mile (Severengiz et al., 2020).

## Discussion

Despite widespread adoption of sharing platforms, empirical evidence on the environmental impacts of sharing remains limited. Our work suggests that the common assertion that sharing is more environmentally benign by nature lacks empirical grounding. Synthesizing findings reported in the existing literature we see that different mechanisms, including supportive logistic operations and consumptions changed due to the sharing are crucial for assessing the environmental effects of a sharing platform.

The expectation that sharing would relieve environmental burdens weighs heavily on the notion that sharing, like other access-based economy models (Tukker, 2015), increases use intensity thus allowing the provision of a fixed amount of utility with smaller product stocks. Indeed, several papers reviewed report reduced environmental impacts due to higher use intensity under sharing models (Amatuni et al., 2020; Kerdlap et al., 2021; Makov et al., 2020; Martin et al., 2019; Schneider et al., 2019; Wasserbaur et al., 2020; Zhang & Mi, 2018). Critically however, other papers reported lower use intensity under sharing, for example, when residential dwellings are converted into Airbnb vacation apartments (DiNatale et al., 2018; Görög, 2020; Jaremen et al., 2020), or when bike sharing platforms flood the market with unneeded stocks (Chen et al., 2020; Ma et al., 2018). Yet even when sharing does increase use intensity, it might not deliver the expected reduction in environmental burdens for several reasons.

First, measures of use intensity often reflect idle time which doesn't necessarily correlate with environmental impacts. For example, within mobility, 90% of carbon emissions are associated with the use phase rather than vehicle production (Allwood et al., 2012). This means that in practice, environmental outcomes are more a function of the passenger-km driven than the number of cars on the road at any given time (i.e fleet size). As such, reducing the number of cars will lead to marginal environmental gains compared to other measures such as increased passenger occupancy (Amasawa et al., 2020; Schäfer & Yeh, 2020; Sun & Ertz, 2021).

Second, different mechanisms either related to the platform or its users could offset some of the expected benefits of increased use intensity. Kerdlap et al. (2021) suggests that the added transport and cleaning services required in stroller sharing offset a large portion of the environmental benefits effectively shifting impacts. Similarly, managing shared scooter and bike stock locations and moving them from one place to the other to meet users' demand in free floating systems can have substantial environmental impacts (Ding et al., 2021; Severengiz et al., 2020; Sun & Ertz, 2021). These examples demonstrate how crucial it is to take platforms' operations and logistics into account when considering their environmental performance.

Third, sharing might not displace the conventional products and services it is assumed to but rather other, more environmental products and services. The literature suggests that 21-61% of ride hailing trips did not displace car rides but more environmental modes of transport such as walking and public transportation (Afroj et al., 2019; Alemi et al., 2018; Clewlow & Mishra, 2017; Gehrke et al., 2019; Lee et al., 2019; Rayle et al., 2016; Schaller, 2018, 2021; Tirachini et al., 2020). Moreover, sharing may trigger added demand increasing overall environmental burdens rather than decreasing them. For example, Rayle et al. (2016) reported that 8% of ride-hailing users surveyed would have otherwise stayed home, Farronato and Fradkin (2018) reported that 42-63% of nights booked on Airbnb would not have resulted in a hotel booking in the absence of Airbnb, and Tussyadiah and Pesonen (2015) found that users of shared accommodations tend to take more frequent, longer vacations.

Last, sharing often saves users money which they then typically re-spend on additional products and services, a phenomenon referred to as re-spending or indirect rebound effect (Meshulam et al., 2023). The rebound effect can occur when platform users save money (by collecting free food for example) and then use these savings to buy other things (Druckman et al., 2011; Makov & Font Vivanco, 2018; Sorrell et al., 2020). Alternatively, rebound can emerge when owners in P2P (decentralized) platforms earn money by sharing their apartments (Cheng et al., 2020) or when yacht owners spend only a portion of their money on maintaining yachts (Warmington-Lundström & Laurenti, 2020). While research on sharing economy rebound effects remains scarce, the existing evidence from accommodations and goods sharing suggests that added consumption (or rebound effects) may negate a substantial part of the expected environmental benefits of sharing.

Taken together, our findings suggest that the digital sharing economy is not “good for the environment” by default. Nonetheless, it is important to note that sharing is not inherently negative either. Many papers propose practical suggestions platforms and their users can take to improve the environmental performance of the sharing economy. Better management of platforms’ supportive logistic operations could improve environmental outcomes. For example, optimizing bike rebalancing practices or extending the lifespan of shared scooters through proper maintenance could substantially reduce GHG emissions (Luo et al., 2020; Severengiz et al., 2020). On the users’ side, actively preferring more environmental benign options such as shared carpooling (e.g. Uber pool) rather than single occupancy ride hailing, forgoing dry cleaning of shared strollers, or deciding to collect free shared food only if it is within walking distance (Cai et al., 2019; Makov et al., 2020; Young et al., 2020)

The sharing economy is a growing phenomenon, increasing its presence in our day to day lives. As this work demonstrates sharing is not inherently more environmental and more work is needed to better understand the specific conditions to make sharing more environmental. Our analysis reveals that factors related to the research design can affect results. Specifically, theoretical studies or those based on expert opinions tended to report more favorable results compared to data driven analyses where environmental impacts were derived based on platform or user data. Furthermore, research which investigated the broader system (e.g. the entire sector or economy) was slightly more likely to report negative environmental outcomes compared to that which looks at the product level. These results suggest that policy makers, researchers and entrepreneurs should look beyond simplistic comparisons of at the single product level to examine the environmental impacts of a potential sharing platform from a full system’s perspective.

## Figures and Tables

| Screening Criteria | Inclusion criteria | Exclusion criteria |
|---|---|---|
| Population (P) | General population, be it individuals, households, or the general public which consume via the digital sharing economy. | Companies using sharing economy principles to share assets (Grondys, 2019). |
| Intervention (I) | Consumption which has physical aspects via the digital sharing economy (e.g shared goods, shared mobility, shared accommodation) | Non-digital forms of sharing such as sharing within households (Ala-Mantila et al., 2016)<br><br>Non physical forms of sharing, such as knowledge and time sharing (Pang et al., 2020) |
| Comparator (C) | Studies report environmental impacts or consumption changes from which environmental impacts can be derived. | Studies report perception of the sustainability of the sharing economy (Laukkanen & Tura, 2022; Puspita & Chae, 2021).<br><br>Studies report user motivation for participation in the sharing economy (Böcker & Meelen, 2017; Nguyen-Phuoc et al., 2022). |
| Outcome | Environmental impacts of the sharing economy | Post-COVID reorientation of the sharing economy (Hossain, 2021) |

**Table 1. Screening Criteria for inclusion / exclusion of studies.**

| Factor related to | Factor | Description |
|---|---|---|
| Platform | Domain & type of resource shared | The type of product shared: shared mobility, accommodation; goods; general sharing economy.<br>For each domain, what resource is shared. For example, for shared mobility: ride- hailing, car sharing, micro-mobility (i.e. bikes and scooters);<br>**Note:** Papers could be assigned to more than one domain and resource shared depending on their content. |
| | Platform size | Defined according to market valuation.<br>Small (under $1 million), Medium (above $1 million, bellow $1 billion), Large (over $1 billion) |
| | Sharing model | For pay, Not for pay (free) |
| | Resource ownership structure | Who owns the stock: centralized ownership - Business to consumer (B2C, also referred to as product service systems PSS) or decentralized - Peer-to-Peer (P2P, also referred to as Consumer to Consumer) |
| Research design | Methodological approach | Quantitative (e.g. LCA, regression, geo-analysis simulation), Qualitative (e.g., interviews, workshops) |
| | System boundaries | **Product** - how a shared item compares to a traditional ownership model. (e.g shared dress vs. owning a dress);<br>**Sector** - how a shared item affects the entire sector (e.g. how using ride hailing affects all transportation choices including public transport and walking);<br>**Entire economy** - how a shared item affects many sectors in the economy |
| | Type of impact examined | **Consumption changes** - research reports behavioral change and environmental impacts can be assumed by readers;<br>**GHG emissions** - research reports expected change in GHG emissions;<br>**Environmental impact** - research reports GHG as well as other impact categories such as water depletion, land use etc. |

**Table 2. Factors examined for empirical papers.** Factors are organized by those related to the platform and its operations, and those related to the research design.

| Paper type | General | Mobility | Goods | Accommodation |
|---|---|---|---|---|
| Empirical (Quantitative) | 5 (2) | 58 (53) | 15 (11) | 12 (10) |
| Book chapter | 6 | 3 | 0 | 1 |
| Lit review | 9 | 6 | 2 | 4 |
| Theoretical | 27 | 2 | 3 | 1 |

**Table 3. Papers by domain, paper type, and qualitative/ quantitative method:** Sharing economy research broken down by domain and publication type. For empirical research the number in brackets reflects quantitative research (as opposed to qualitative research) N=154 due to 2 papers which are counted as both mobility and goods.

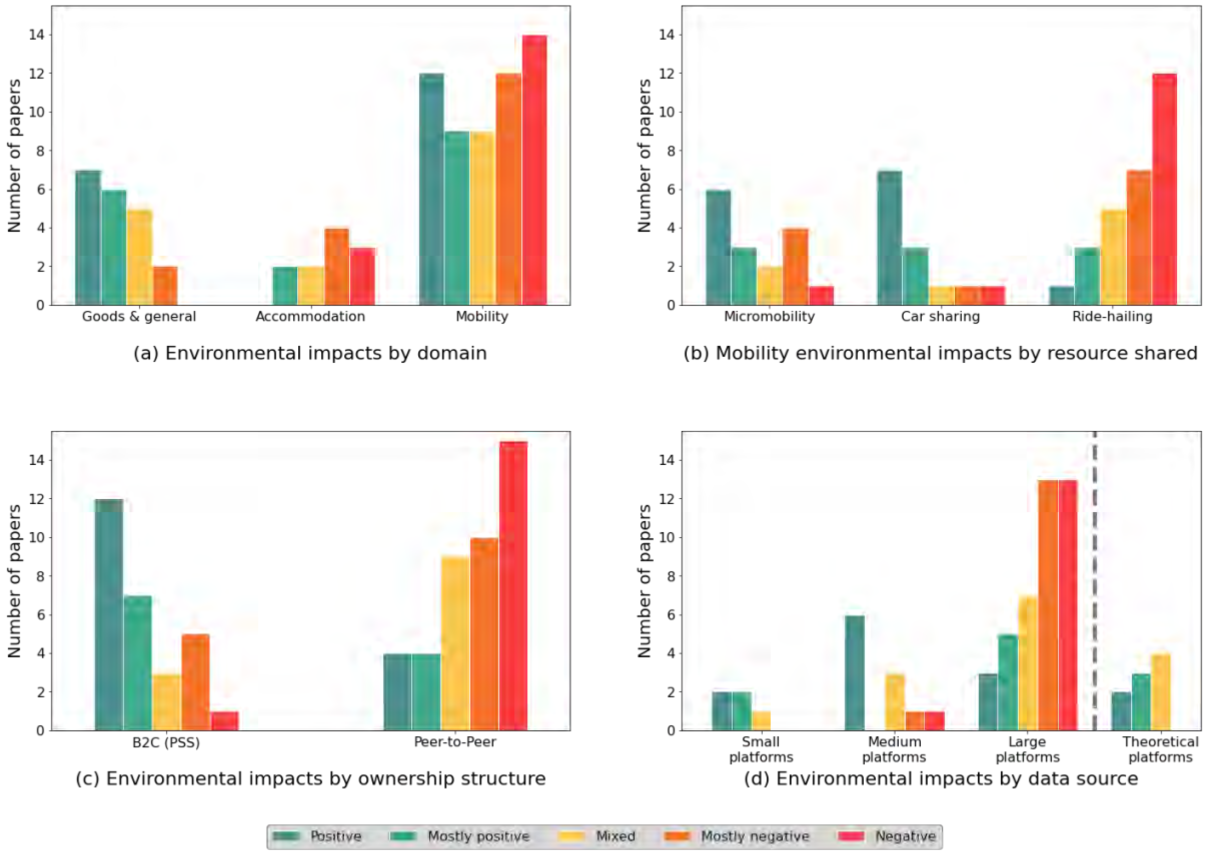

**Figure 1. Environmental Impacts by different platform variables:** Findings are presented by environmental impact according to a score assigned to each empirical paper, and selected platform characteristics. The environmental impact score was given on a scale from 1-5, with 1 indicating positive impact and 5 indicating negative results. Dotted line in panel (d) separates results for actual platforms (noted according to size) from hypothetical platforms. For tabular representation see SI sections 5-8.

# Engaging consumers in reusable packaging systems: An exploration of factors influencing the adoption

**Xueqing Miao[(a)], Lise Magnier [(a)], Ruth Mugge[(a,b)]**
a) Delft University of Technology, Delft, The Netherlands
b) University of Amsterdam, Amsterdam, The Netherlands

**Keywords**: Consumer behaviour; Reuse; Packaging lifetime; Environmental impact.

**Abstract**: Reusable packaging systems (RPSs) show promise in replacing single-use packages by extending the packaging lifetime and significantly reducing waste. Yet, knowledge about consumer behaviour in the adoption of RPSs is scarce. We present in-depth insights into how consumers perceive RPSs as a new shopping pattern for fast-moving consumer goods (FMCGs). Our findings reveal that consumers' high willingness to adopt RPSs stems from their awareness of waste and their desire to reduce it. Nevertheless, various reasons can complicate the process of adoption. First, consumers perceive reduced behavioural control in this new shopping pattern and are reluctant to invest extra effort or alter routines. Next, consumers weigh economic benefits to compare alternatives at the point of purchase and are generally unwilling to pay a premium for RPSs. In addition, even though consumers trust the hygienic standard of the RPS, they raise contamination concerns when they notice spillage, other consumers' improper use and signs of usage generated on the packaging. In terms of environmental impact, consumers experience positive feelings about reducing packaging waste but also perceive the environmental impact as vague and doubt the effectiveness of their reuse behaviour. To encourage the adoption of RPSs, these barriers need to be addressed via design and marketing interventions.

## Introduction

Fast-moving consumer goods (FMCGs) have become an integral part of our daily lives. Most FMCGs are packed in packages with a short lifetime designed for single-use followed by disposal (Bocken et al., 2022). Consequently, the volume of packaging waste is staggering. In 2020, the EU generated around 177.2 kg of packaging waste per capita, amounting to a total of 87 million tonnes (Eurostat, 2022), which poses a significant environmental threat through littering, landfilling and incineration.

Prolonging the useful lifetime of FMCG packaging could reduce the detrimental effects of our daily consumption (Ertz et al., 2017). One way to achieve this is by implementing reusable packaging systems (RPSs) that consist of long-lasting packages designed for multiple uses in a closed-loop system. RPSs can be broadly divided into two types (Greenwood et al., 2021; Muranko et al., 2021): (1) returnable packaging systems, where the companies in the supply chain repeatedly clean and refill the packaging with products and (2) refillable packaging systems, where consumers are responsible for the cleaning and refilling of the packaging. Some RPSs can integrate features of both types into one system (Coelho et al., 2020). For example, in the RPS we investigated in this study, consumers can either repeatedly refill and clean the same packaging or return the packaging to the company to be cleaned and then reused by another consumer.

Previous studies have focused on the logistics and material aspects of RPSs to improve their sustainability and economic viability (e.g. Blanca-Alcubilla et al., 2020; Cottafava et al., 2021; Kunamaneni et al., 2019). Our study contributes by understanding consumer adoption which is crucial for RPSs to have the desired positive impact.

## Theoretical background

Previous research has shown that consumers who perform reuse behaviour are influenced by knowledge of environmental issues (Barr et al., 2001). Consequently, individuals with greater environmental concerns are more likely to use reusable packaging, as they perceive it as valuable for reducing packaging waste (Lofthouse et al., 2009; Magnier and Gil-Pérez, 2021). Refilling products from bulk enables consumers to control the product amount and be less restricted concerning packaging size, which also adds environmental value in terms of food waste reduction (Beitzen-Heineke et al., 2017). Furthermore, economic incentives such as rewards (e.g. loyalty points, discounts), deposit schemes (i.e. paying an up-front deposit to borrow the packaging) and subscriptions (e.g. scheduled deliveries for refill) can encourage consumers to continue using RPSs (Wastling et al., 2018). However, it remains unclear whether these factors are sufficient to make RPSs an attractive option for the majority of consumers.

RPSs are currently far from the norm. Consumer actions can be hindered by a lack of accessibility to the system and a sufficient range of product categories (Beitzen-Heineke et al., 2017; Greenwood et al., 2021). Moreover, most FMCGs are low-involvement products, for which consumers are unlikely to conduct extensive information searches and invest cognitive effort in reusable alternatives. Habits drive consumers to pick a product they usually buy (Kunamaneni et al., 2019). Changing these habits requires consumers to question the status quo and adapt their routines (Bocken et al., 2022). Yet, moral reasons for a sustainable choice are only likely to prevail when consumers do not have to compromise on other product characteristics, such as convenience and price (Olson, 2013). Using RPSs is perceived as inconvenient and costly, resulting in a shopping experience that consumes much time and effort (e.g. returning empty packaging or refilling products in-store); and potentially higher product costs or an upfront deposit for the packaging (Jiang et al., 2020; Zhu et al., 2022). Furthermore, the packaging is expected to ensure product hygiene (Lindh et al., 2016), whereas the wear and tear on reusable packaging due to frequent washing, transportation and refilling can act as a contamination cue, activating concerns about health and safety (White et al., 2016) and thus hindering acceptance. Some hygiene issues also emerge in the use context of RPSs, such as sharing the use of the system with unfamiliar users or seeing others touch the packaging (Long et al., 2022).

Although previous studies are valuable for understanding consumer behaviour towards RPSs, most insights were gathered from hypothetical usage scenarios and did not capture what it would mean for consumers to use an RPS in real life. This paper contributes by exploring consumer responses to the actual usage of an RPS in a lab setting and packaging usage at home. We identify influencing factors in consumers' adoption of RPSs as a new shopping pattern.

## Method

We conducted semi-structured interviews with 27 participants. All participants were selected from a university-based research panel and were selected to show variety in age (18-74 years, mean: 50.6 years), gender (44% male; 56% female; 0% other), monthly income and education level. Each interview session consisted of two parts. First, in-person interviews took place in a university lab facility, where an RPS was installed (see Figure.1).

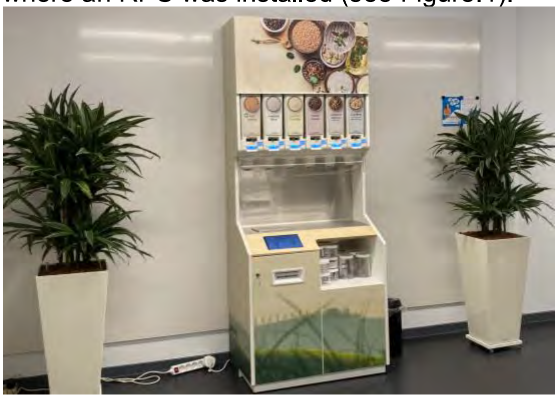

**Figure 1. Research set-up.**

Each participant was asked to use the RPS to dispense products in three different packages: two reusable packaging of different sizes and one private container brought by the participant. Subsequently, participants described their general feelings about operating the RPS, packaging preferences, what would motivate or hinder their adoption, and the perceived environmental impact of RPSs. After the interviews, participants took one of the reusable packages they had filled and used it at home. The second part consisted of follow-up phone interviews to understand consumers' usage of reusable packages at home.

All interviews were audio-recorded and fully transcribed. The data was analyzed and coded using Atlas.ti software.

## Results and discussion

Our study found that participants were generally aware of the packaging waste issue. Most participants expressed a desire to buy products with less packaging and had a positive attitude about eliminating packaging waste through using RPSs. Yet, only a few participants believed that they would adopt RPSs in their shopping practice due to the perceived challenges of starting and sticking to them in a long term. More in-depth insights revealed that several aspects influence consumers' adoption of RPSs, including behavioural control, economic incentives, contamination concerns and environmental impact.

### *Behavioural control is challenged*

Our study revealed that consumers faced difficulties controlling their behaviour when they used the RPS as a new shopping pattern. Perceived behavioural control, as defined by Ajzen (1991), refers to a person's perception of the ease or difficulty of performing the behaviour of interest. Our insights showed that behavioural control of RPSs referred to two aspects: operating the system and altering the shopping routine.

Participants reported that using an RPS was initially challenging. Understanding the digital instructions to operate the system and reading product information separated from the packaging increased consumers' cognitive load and resulted in time costs. Manually controlling the product flow could cause spillage and decrease consumers' perceived ability to use the RPS. Participants also expressed anxiety about occupying the system for a long time in a busy supermarket. To avoid these negative emotions, some participants preferred to get products from the shelf for a higher level of behavioural control.

> *'I think this is quite difficult to understand. Perhaps there are people waiting behind you. I will do it another time and I try to follow the procedure when there's nobody waiting for me because that makes you a little bit nervous.' (P6)*

In comparison to the convenience of single-use packaging's disposal after usage, participants perceived RPSs as requiring extra effort in packaging management (e.g. cleaning and bringing it back for reuse). Participants stated that altering shopping routines to fit this new shopping pattern was also challenging. For example, they may easily forget to bring the packaging while doing spontaneous shopping.

> *'You have to remind yourself to bring this before you go. It's difficult when you do spontaneous shopping.' (P13)*

### *Economic incentives are often expected*

Our results reveal that economic incentives may act as an enabler for consumers to adopt RPSs. Participants recognised that RPSs enabled them to spend less money on small portions of the product rather than being restricted by predetermined (large) packages, as well as save cost in waste collection charges due to less packaging waste generated in their household.

Yet, participants noted they only evaluated these incidental economic benefits afterwards, while most decisions were triggered by tangible incentives such as discounts and promotions at the point of purchase. While some participants showed explicit reluctance to pay a premium for RPSs and claimed that reuse behaviour should be rewarded, others expressed a willingness to pay a small premium considering the manufacturing and operating costs of the system.

> *'Buying food from this dispenser system should bring you some profits in the price. The system rewards you because you bring your own container. I think it's important that buying in this way will save you some money because you have to do more.' (P10)*

### *Contamination concerns emerge during the usage*

The adoption of RPSs requires consumers to share access to the system with other consumers and repetitively use the packaging. Nevertheless, these may raise contamination concerns that hinder consumer adoption of RPSs or trigger early replacement of reusable packaging. Contamination is usually driven by three mechanisms, namely hygiene, utility and territory (Baxter et al., 2016). Our findings suggest that all three contamination mechanisms may occur for RPSs.

First, participants generally trusted the hygienic standards of RPSs when products were stored in airtight bags, the dispensing process was contactless and reusable packages were professionally cleaned and (re)sealed. Yet, some participants reported that observing spillage around dispensers and improper reuse behaviours of other consumers activated their hygiene concerns.

> *'People bring their own containers and they are not clean. Their containers are touching the machines and get some cross-contamination as well.' (P2)*

Next, participants associated the signs of wear and tear on the packaging that may appear over multiple reuses with bacteria. Some participants stated external scratches were more acceptable than internal scratches in contact with the (food) products which represented contaminants and posed a threat to their health. Participants would swap the packaging or switch to their private containers.

> *'There are scratches. It may cause a hygiene issue because if there are scratches, there may be bacteria in the scratches.' (P6)*

In addition, participants deemed the packages with severe scratches or damages less acceptable because they perceived a decreased functionality (e.g. unable to see through the packaging) that triggered concerns about utility contamination (Baxter et al., 2017; Wallner et al., 2022). Participants also associated damages with prior usage by strangers and inferred how these damages occurred. This evoked territorial contamination concerns that resulted from an object perceived as belonging to someone else (Baxter et., 2016).

> *'If you see it is a little bit damaged, I would not be happy about it. Even though you do know that it is reusable and therefore it has been used by someone else, you think how can this have happened?' (P20)*

### *Environmental impact is vague*

While most participants recognised the relation between FMCGs consumption and single-use packaging waste, they perceived the environmental impact of RPSs as vague. Drawing from the construal level theory (Trope and Liberman, 2010), positive environmental impacts are often distant in time and space from where the consumption takes place, which makes it difficult to assess the actual impact (White et al., 2019). Some participants distinguished the impact by observing a near-future phenomenon, such as having less packaging waste in their trash bin, because it made their actions more concrete and vivid than assessing the impact on the environment.

> *'I think we would notice the reduction of waste. And you also see that your bin isn't filled that quickly with all those extra plastics. I would feel really good for myself.' (P4)*

Although most participants exhibited a positive feeling about seeing waste reduction at an individual level, they remained uncertain about whether using RPSs would save natural resources at a systematic level. Some participants believed that the raw materials and energy involved in manufacturing and maintaining reusable containers and systems would probably be as detrimental as single-use packaging. This lack of knowledge contributed to their uncertainty about the consequences. Therefore, some participants desired to receive transparent information about the environmental impact of RPSs.

> *'I'm not sure whether this is more environmentally friendly than just producing a new container that isn't reusable. You can also make the packaging cheap and not use so many raw materials.' (P23)*

Furthermore, participants reflected that individual reuse had a limited effect and that only when most consumers participated in collective actions can RPSs make a real difference. Participants also questioned how many cycles a reusable container should complete in its lifetime, although most of them did not estimate the packaging's lifetime and would just use it '*until it is broken*'. It is worth noting the importance of ensuring reusable packages complete a certain number of cycles before consumers consider them unacceptable and be environmentally better than an equivalent single-use package (Baird et al., 2022).

## Conclusion

This study contributes to understanding consumer perception and adoption of RPSs and provides valuable insights for future implementation. Our findings highlight the importance of design and marketing interventions that can engage more consumers in RPSs.

First, to activate reuse behaviour, it is crucial to increase the exposure of RPSs in the market by expanding the availability and compatibility of RPSs to facilitate refill or return behaviour in different stores. Previous studies suggested minimising the complexity of the system and providing consumers with a smooth experience (Mahmoudi and Parviziomran, 2020). We further indicated that clear instructions and sufficient product information could enhance consumers' control over their behaviour.

At the point of purchase, although economic incentives may act as an enabler for consumers to adopt RPSs (Muranko et al., 2021), our study shows they need to be explicitly communicated and assist consumers in comparing the economic benefits of alternatives with low cognitive load.

In addition, we enrich the understanding of contamination concerns. We demonstrate that although consumers have a high level of trust in the hygienic standards of RPSs, contamination concerns that emerge in their usage can hinder adoption. To address this issue, a well-designed RPS should minimise the risk of spillage and provide reusable packaging resistant to severe wear and tear. Regular maintenance and an indication of a hygienic condition for reuse can also prevent consumers' negative associations.

Furthermore, our study adds consumer perception regarding the environmental impact of RPSs in the literature. We observed a desire among participants to understand and associate their behaviour with the environmental impact of RPSs. Uncertainty about the consequence of RPSs can evoke consumer scepticism. Thus, we suggest that RPSs could provide tailored feedback about personal reuse behaviours at regular intervals, allowing consumers to compare their environmental impact and keep track of their progress over time. Alternatively, providing information about the collective environmental impact of all consumers at the store can communicate the power of collective action (Ran et al., 2022).

We encourage future research to build upon these findings to engage consumers in RPSs and contribute to a more sustainable society.

# Making circuits more circular: An overview of main obstacles of the independent electronics repair sector and the possible policies to promote their operation

**Magdolna Molnár** [(a)]
a) University of Regensburg / Technical University Brandenburg, Germany

**Keywords**: Circular economy; Repair; Policies; Electronics.

**Abstract**: This paper gives an overview of the main obstacles to independent repair businesses for electronics and highlights some policy measures that could potentially intensify the demand for their services. The findings of this paper are based on a rapid literature review and interviews conducted with independent repair service providers and NGOs of the right to repair. As repair can play an important role in resource efficiency, local job creation and in enhancing more sustainable consumption practices, it is vital for the European and national authorities to promote repair activities. To avoid a monopoly of OEMs over the sector, that could obstruct innovation and could limit price competition, it is crucial to put more focus on independent repair shops in policy measures.

## Introduction

As a consequence of increasing geopolitical interest for resource efficiency in Europe, as waste management problems are intensifying, as repair can constitute an important tool for extending the lifetime of devices in circular economy strategies, and as demand from consumers for more durable and repairable products and repair rights is surging, the previously 'invisible' and neglected task of repair (Graham and Thrift 2007) has been recently getting more policy attention. In this paper the focus will be on the repair of electronics, as discarded electronic equipment has become one of the fastest growing and most problematic waste streams (Forti et al. 2020), largely due to the decreasing lifetime of consumer electronics caused by technological, legal, economic, and social reasons, as it will be explored in this paper.

Since the manufacturing and shipping of final electronics dominates the resource depletion impact throughout the products' whole life cycle (Liu et al. 2019) and as there are also serious social issues associated with mining and manufacturing processes involved (Mannhart et al. 2016), it is vital to prolong the lifetime of these devices with repair. To limit the scope of this paper, the independent repair sector will be the focal point of the work, as their role is important in ensuring a fair competition for repair services. Previous studies (eg. Svensson-Hoglund et al. 2021) found that current polices mostly neglected the competitive disadvantage of independent repairers and of community repair, while original equipment manufacturers (OEMs) continue to have a great control over the sector. The aim of this paper is to give an overview of the main barriers for independent repair businesses and to propose some policy tools to overcome them.

## Methods

As part of this paper a rapid literature review was conducted, as the aim was to explore and to assess what is already known about policies for a recent area of study (Grant and Booth 2009), in this case for the independent repair sector of electronics. An advantage of rapid reviews is that they do not require the same extensive review time or scope as systematic reviews (Temple University Libraries 2020), however they can still give a synthesised overview on insights in a dynamic topic (Watt et al 2009, Grant and Booth 2009), which seemed suitable, as this work was composed during the first stage of a PhD study. Materials for the review were found using Google Scholar and Scopus, with a timeframe of the last five years (January 2018 – February 2023), focusing on the search words repair, electronics, ICT, barriers, policies. In the literature selection process, it was aimed to cover all possibly categories of obstacles: technical, legal, economic, and social. In this way 16 relevant papers were selected and 4 more were added through the snowball search method from references, as well as 5 more papers were recommended by the interview partners. The full list of selected literature can be found in the references section. The review materials were then extended with own semi-structured interviews conducted between October 2022 and March 2023 with actors of the Right to Repair campaign (n=5), and independent repair providers (n=5) operating in Germany and in Austria (definition in Figure 1), on their insights in the repair sector.

Figure 1: Main providers of repair services for electronics

| Independent repair businesses | Repair facilities authorised by OEM schemes |
|---|---|
| Mostly operate without contracts with OEMs | Licenced by OEMs and work according to their required standards |
| Mainly out-of-guarantee repair | Also do repair within the guarantee period |
| Limited access to required information, hardware, software and tools | Access to repair information, tools and spare parts |
| Several brands covered | Mostly brand limited |
| Mainly SMEs | SMEs or larger workshops |

## Findings

### *Main obstacles to independent repair businesses*

Figure 2: Main obstacles to repair of ICT electronic devices at independent repair shops

| Technical / Design | Legal | Economic | Social |
|---|---|---|---|
| Increasingly complex and non-modular design, miniaturised parts, lack of standardisation | Limited scope of the EU ecodesign regulations | Externalisation of environmental and social costs – cheap manufacturing | Low trust in repair services |
| Software and hardware interoperability issues (part pairing) | Lack of criteria to prioritize repair in waste frameworks | Labour intensity of repair, high labour costs and expensive spare parts and tools- expensive repair | Lack of knowledge about consumer rights |
| Lack of or expensive spare parts and tools | Barriers due to intellectual property rights, copyright and trademark regulations | Low wages and limited profitability of repair businesses | Lack of information about the repairability, durability and resource footprint of a product |
| Shorter innovation cycles and limited availability of software updates | Shortcomings in guarantee conditions, excluded independent services | Decreasing demand for repair services | Inconvenient repair infrastructures and easier access to purchasing new products |
| Trade-offs between durability and repairability (water resistant products) | Chemical rules and WEEE transport restrictions can restrict the re-use of spares parts | Lack of technical labour force | Psychological obsolescence, novelty seeking and low desirability of repair |
| Lack of access to technical information, diagnostic software and training | Lack of regulation on planned obsolescence | Monopolisation of repair services by OEMs | Decreasing interest in gaining technical skills on repair for professional or occupational activities |
| Difficulty in providing repair services to a large range of products and brands | Strong lobby of manufacturers and limited transparency of decision making | Largely linear production and consumption patterns | Consumption is encouraged by current legal, economic and social environment |

*Source: own figure based on own interview materials and on Svensson-Hoglund et al. 2021, Manoochehri et al. 2022*

**Figure 2. Main obstacles to repair of ICT electronic devices at independent repair shops © own design, based on own interview materials and on Svensson-Hoglund et al. 2021, Manoochehri et al. 2022.**

As shown in Figure 2, one of the main difficulties for repair businesses are the technical obstacles. In a survey with independent repair shops, Türkeli et al. (2019) found that mobile phones are becoming more difficult to repair. This is largely due to the non-repair friendly design measures of producers, such as the tendency towards more integral and less modular devices resulting partly from water-resistant designs, bundling of parts, miniaturisation, software or hardware interoperability issues, fast innovation cycles, part pairing, premature obsolescence due to low-quality materials and software update limitations (Clemm et al. 2019, Türkeli et al 2019, HOP 2022). As the business of OEMs are driven by the volume of product sales, they are not incentivised to enable and engage in repair activities in the current market and policy context (Svensson-Hoglund et al. 2021). Thus, is their interest to make hardware, tools, software, repair information and training expensive or not available at all for independent repair businesses.

**Legal obstacles** are also responsible for hindering independent repair businesses. These include: 1. the lack of prioritization of repair and reuse in the compulsory reporting mechanisms for the Waste Framework Directive and EPR regimes, 2. the restrictions on the international transport of WEEE and on the chemical substances obstructing the mining for spare parts from used devices, 3. infringements on intellectual property rights resulting from using non-authorised parts or unlocking devices with non-authorised software, 4. shortcomings in consumer laws, such as warranty and guarantee conditions that block independent repair shops from offering services within the guarantee period, and 5. the lack of clear legislative measures to oppose planned obsolescence (Perzanowski 2021, Svensson-Hoglund et al. 2021, Nogueira 2022). Though, the recent update of the EU battery directive and of the EU eco-design framework introduced some compulsory reparability criteria, including design for easier dismantling, requiring availability and access to spare parts and access to information for professional repair providers, have been important policy advancements. However, not all electronics are covered by these measures, and extending them product-to-product will require years before a comprehensive scope is reached.

Furthermore, the interviewed NGOs involved in the right to repair process emphasised that these measures have been watered down from the initial objectives, leaving significant advantage to manufacturers. For instance, the current ecodesign framework only requires indicating the pre-tax prices for spare parts, part pairing is not prohibited, and ‘professional repairers’ remain vaguely defined in the proposal leaving room for manipulation. In the interviews it was also highlighted that due to the often untransparent nature of the European legislative process, the strong lobby of manufacturers and retailers, and lack the of technical expertise among most policy makers, certain corporate interests have been overrepresented in the European decision-making processes hampering repair rights for independent businesses.

According to a survey contacted in Flanders by the Repair&Share (2021), repair no longer seems to be an economically attractive profession. The main **economic challenges** for the independent repairers are the high costs of repair services combined with difficult access to and high price of spare parts, and the low costs of replacing with new cheap mass products (McCollough, 2019), constitutes a ‘systematic or economic obsolescence’ for this sector (Paech et al 2020). The high cost of repair has been revealed as a main discouraging factor for consumers (Wieser & Tröger 2018, Dalhammar 2020, Laitala et al. 2021). Overall, the repair sector has been found to be declining in Europe, evidenced by the gradually contracting turnover of the European repair businesses and the dropping number of people employed fulltime in the sector between 2017-2019 (Manoochehri et al 2022). The high price for repairs is driven by high labour costs in Europe, which is combined with labour intensive tailor-made repair services due to the complexity of products, while as a result of externalisation of environmental and social costs production of new devices remains cheaper. On the top of this, independent repair shops also have to compete with the growing attempts by OEMs to monopolise the repair sector with their restrictive measures, especially as extending the profit streams of traditional producer business models with eg. service-based economic opportunities, providing repair services is becoming more attractive for manufacturers (Vezzoli et al 2021).

**Social barriers** and the preference of consumers also create significant barriers to independent repair businesses, as demand has been decreasing for their services (Fachbach et al. 2022). Previous studies have demonstrated that consumers’ decision for repair is complex and not completely rational process, despite the technocratic approach that public policies often try to take (Rogers et al. 2021, Nogueira 2022). The lack of knowledge about consumer rights and about the availability of repair services, as well as the lack of trust (Laitala et al 2021, Svensson-Hoglund et al 2022); which is partly due to the difficulty to predict prices prior to performing repair; the inconvenience of repair services and novelty seeking, especially when it comes to smart phones (Jaeger-Erben et al. 2021); low consumer expectations of the durability and reparability of products (Wieser and Tröger 2018) and psychological obsolescence (Makov et al 2021); increased acceptance of a throw-away culture (Mandl und Tröger 2020); and social stigma on repair seen as an act of necessity (Rogers et al. 2021) are all important factors discouraging people from repair. In fact, the general engagement in repair has been observed to be declining in industrialised economies, however, the recent resurge of DIY repair and emergence of repair cafés have been seen a positive societal development (Bertling and Leggewie 2016, Jaeger-Erben und Hielscher 2022).

## *Possible policy measures*

**Figure 3: Policy measures that can support repair services on ICT devices in independent repair shops**

| Regulatory measures | Fiscal and market measures | Information and communication measures |
|---|---|---|
| Extending the scope ecodesign – horizontal, not product by product (more and more smart products) | Tax reform and VAT tax reduction on repair services | Supporting additive manufacturing and other open technology |
| Labelling by an independent authority (resources) | Repair bonus | Offering and subsiding vocational training and other educational programmes |
| Extended compulsory warranty and guarantee period and consumer rights | Income Tax Deductibility of Repairs | Awareness campaigns, supporting repair cafés, ads |
| Legislation against planned obsolescence | Eco-modulation of the producer fee under the EPR scheme | Making European and national law-making process more transparent |
| Digital Product Passport | Manufacturers have to pay for the true environmental and social costs of products | Supporting R&D for circular business models |
| Green public procurement | Reformed advertising | More information on consumer rights |
| Prioritising reuse and repair in reporting mechanisms | | National registry of licenced repair shops |

*Source: own figure based on own interview materials and on Piringer et al 2022 and Nogueira 2022*

**Figure 3. Policy measures that can support repair services on ICT devices in independent repair shops © own design, based on own interview materials and on Piringer et al 2022 and Nogueira 2022.**

After giving an overview of the main barriers to the operations of independent repair workshops, this part of the paper will highlight some possible policy measures to support their businesses, as summarised in Figure 3. By influencing the framework conditions and providing financial incentives, policy makers can play a key role in influencing the competitiveness of the independent repair sector (Svensson-Hoglund et al., 2021, Manoochehri et al 2022, Piringer et al 2022). Policy makers have in principle four main tools to incentivise repair (Nogueira 2022): 1. Regulatory measures 2. Fiscal or market measures 3. Information and communication instruments and 4. Self-regulation measures. In this paper only the first three categories will be analysed, as voluntary market mechanisms and industry-lead self-regulative initiatives cannot promote independent repair to a large extent, as these businesses are largely against the business interests of OEMs.

As discussed in the first part, even if the ecodesign legislation was an important **regulatory measure** for the repairability of electronics, its scope in terms of criteria and product category must be extended to truly support independent repair. Introducing elements of competition law to the design requirements would also be essential to establish more equal competition in the repair sector. Moreover, ensuring more repairable design for new products, do not necessarily mean durability of these products, thus devices prone to premature obsolesce due to their poor design should be banned from the market. On national level there has been some advancements for the penalisation of intentional obsolescence, for instance in France and Italy, however, on EU level there has been only initial steps taken with the EU Omnibus Regulation (Nogueira (2022). Another positive development that started on the national level, in France, is the reparability index for electronics. The French index will be extended with some durability criteria in the next years, and European label is currently under discussion. However, it would be important improve the French model and to require an independent authority to set the scores, instead of the currently self-declared system by manufacturers (HOP 2022). During the interviews it was also suggested to include information on the products about their resource footprint to show their real environmental impact. Nevertheless, the effect of ecolabels might be limited, as there are already many voluntary ecolabels on the market. The European Digital Product Passport is also currently under preparation, and if the data will be accessible for all repair services, it has the potential to provide important product information on the technical specifications of devices (Götz et al 2022). Furthermore, making the currently voluntary green public procurement compulsory would be also an important measure that could expand the market for independent repair businesses (Mélon 2020). Another regulatory measure option could be to have more focus on upstream waste reduction, for instance by extending EPR systems for reuse and repair activities, like De Kringwinkel network in Flanders. Finally, more policy attention should be on setting up strong market surveillance bodies to enforce all regulatory measures (Nogueira 2022).

**Fiscal and market measures** are currently largely underexplored tools to incentivise repair, as most EU policies on circular economy tend to resort to market self-regulation and nudging of consumers with soft measures (Nogueira 2022). However, as the core concept of repair is against the current linear market principles, it is inevitable to intervene in market mechanisms. On national level, some fiscal measures have been introduced to make repair services for out-of-warranty devices more competitive against replacements, such as the repair fund in France financed by the EPR fees of manufacturers, and the repair bonus in Austria and in two German states, Thuringia and Saxony. Despite, the general negative economic trend for the independent repair industry (McCollough and Qiu 2021, Manoochehri et al. 2022), some interview partners from independent repair shops were optimistic about the outlook of their businesses, as they currently experience higher demand for their services, which they credit to the repair bonus. In both Austria and Germany, mainly smart phones were repaired with the repair bonus (Eisentraut 2021, Piringer et al 2022), which due to their average short lifetime, suggests an important environmental impact. Nevertheless, it is uncertain whether the repair bonus can generate a long-term demand for repair services and whether the higher interest of repair is due to the current economic recession. Tax exemptions for repair services have also been tested in member states, however, in most countries they do not apply to electronics (RREuse, 2017; Almén et al. 2020). In Sweden the VAT reduction is supplemented with tax breaks for labour costs of repair of for certain electronics devices if the repair takes place in the owner's home. However, there has been limited effect of the Swedish tax reduction to encourage demand for repair, as prices of new products remain lower and only consumers with taxable income are eligible for it (Almén et al. 2020). A study has found that manufacturers might try to compensate for stricter repair rights with temporal reduction of prices of new products, and higher production and disposal rates (Jin et al. 2022). Hence, for a real transformative change to a circular economy, it is essential to raise the costs for new devices. Natural resources and consumption could be higher taxed, while lowering labour costs, which would then also limit the possible rebound effects of savings on cheaper repairs. However, there is limited implementation experience for this model (Almén et al. 2020, Rogers et al 2021).

**Information and communication measures** such as awareness-raising campaigns on consumer rights, registries for licenced repair shops and the European Repair Information Form offering more transparent pricing, once they are implemented, will be important steps to attract consumers to repair businesses. However, individuals are not completely rational in their decisions to get devices repaired, as they engage in a complex spatial, temporal, social, political, economic, and cultural system, however, the current largely technocratic polices do not address these **social aspects** (Kovacic et al. 2019, Rogers et al, 2021). Thus, it would be vital for policies to fund more environmental educational programmes in schools that emphasise the importance of slower consumption and repairing. Furthermore, since it is difficult for independent repair businesses to attract skilled labour force (Laitala et al. 2020, Piringer et al 2022), there should be more funding also available for vocational training. As repair is highly labour intensive, it has been calculated that expanding the repair sector would create more local jobs than the recycling sectors (Ribeiro-Broomhead und Tangri 2021) and could offer skill development opportunities for people excluded from the labour market (Rogers et al 2021). Advertisements for repair activities could also be supported, while limiting ad materials on driving consumption (Piringer et al 2022), and it must be prohibited to block independent repair services from advertising on large digital platforms (iFixit 2019). In addition, technical information must be openly accessible, for instance, by lowering legal burdens for using additive manufacturing for spare parts, which then could stimulate not just independent repair shops, but also community repair initiatives. Repairing can constitute a 'creative transgression' (Reno 2016: 102) in capitalist markets, repair cafés offer a way for people to participate in the circular economy (Van der Velden 2021), and they make repair visible in the public space (Jaeger-Erben und Sabine Hielscher 2022). Moreover, repair cafés do not create any competition against independent repair shops, in fact, as an interview partner highlighted, devices unrepairable at repair cafés often get referred to independent repair shops, thus generating extra marketing for their services.

## Conclusion / Discussion

This paper gave an overview of the main obstacles to independent repair businesses for electronics and highlighted some policy measures that could potentially intensify the demand for their services, based on a rapid literature review and conducted interviews. As repair can play an important role in resource efficiency, local job creation and in enhancing more sustainable consumption practices, it is vital for the European and national authorities to promote repair activities. To avoid a monopoly of OEMs over the sector, that could obstruct innovation and could limit price competition, it is crucial to put more focus on independent repair shops in policy measures. It must be highlighted that more research is needed on the implementation success rate of current polices to give evidence for the most effective measures, however, it can be said that there is no silver bullet to create a favourable legal, market and social environment for independent repair businesses, as repair has to be reintroduced as an essential part to our economies and everyday practices. Policies must be a mix of soft and hard measures covering legal, economic, social aspects. A transformative change from a linear to a circular economy, with repair as its focal point, requires that the current production and consumption patterns are challenged. It is not enough to encourage more repairable products on the market with the ecodesign measures. Non-durable devices should be banned, externalisation of true production costs should be blocked, the repair of devices should be made accessible and affordable, and repair as practice must be popularised. However, exclusively top-down measures cannot bring a societal change, thus bottom-up initiatives, such as repair cafés should also be supported. By relearning to appreciate repairing, we might be able to fix our broken world.

## Acknowledgments

This work is funded by the German Federal Environmental Foundation (Deutsche Bundesstiftung Umwelt). I would like to thank all my interview partners for helping this project.

# Understating the Processing Challenges of Biobased, Biodegradable Polymers used for Packaging Applications

**Anindita Mondol[(a)], Farhad Ein-Mozaffari[(a)], Ehsan Behzadfar[(a,b)]**

a) Chemical Engineering Department, Toronto Metropolitan University (Ryerson University), Toronto, ON, Canada M5B 2K3

b) Sustainable Packaging Lab, School of Graphic Communications Management, Toronto Metropolitan University (Ryerson University), Toronto, ON, Canada M5B 2K3

**Keywords**: Sustainable packaging; Biobased polymers; biodegradable polymers; Innovative packaging; Plastic waste.

**Abstract**: Over the last few decades, sustainable development has become one of the major global initiatives in food packaging, which produces great amounts of non-degradable plastic waste. Polyhydroxyalkanoates (PHAs) are bio-based, biodegradable polymers that have the most potential to replace conventional polymers used in food packaging. To meet the packaging needs for foods, PHAs must be designed to achieve low production costs and better performance, e.g., tunable mechanical properties, crystallinity, surface properties, and degradation rate. The most common members of this class are poly (3-hydroxybutyrate) (PHB) produced by bacteria and its copolymers with 3-hydroxy valerate, which are semicrystalline thermoplastic polymers. In this study, the processing challenges of PHB in industrial settings are examined. Differential scanning calorimetry (DSC) was used to monitor the thermal behavior of PHB and PHBV (featuring 2% valerate content) at a wide range of cooling rates of 5 °C/min, 10 °C/min, and 50 °C/min. The experimental results showed that PHB and PHBV have different thermal responses as the cooling rate changes. When the processing conditions change, the crystallization behavior of both PHB and PHBV change, influencing their ductility, transparency and barrier prosperities. The difference in thermophysical behavior highlights the properties of these bio-sourced and biodegradable polymers that must be improved to tolerate the industrial processes and serve the application requirements.

## Introduction

Plastic has been extensively employed in packaging, transportation, and pharmaceuticals. It is a successful innovation with several excellent qualities, including thermal insulation, electrical insulation, and thermal properties (Lambert & Wagner, 2017) [1]. Traditional plastics derived from petroleum are extensively utilized because of their great strength, long lifespan, stability, and sophisticated manufacturing techniques (Chen et al. 2017) [2]. From 1950 to 2015, an estimated 8.3 billion tons of plastics were manufactured, of which 9% were recycled, 12% were burnt, and 79% remained in landfills or nature (Geyer et al. 2017)[3]. Decomposition is challenging with petroleum-based plastics due to their inherent hydrophobicity, high molecular weight, and additives like antioxidants and stabilizers (Chen at al. 2017) [4]. It takes hundreds of years for most plastics to disintegrate totally in the environment. When non-biodegradable plastics are discharged into the environment, they cause major environmental pollution that is harmful to the ecosystem and eventually threatens human health (D. K. A. Barnes et al. 2009; S. J. Barnes 2019; Lin et al. 2018; Zhao et al. 2018) [5].

Polymer compounds that naturally degrade, such as polybutylene succinate (PBS), polyhydroxyalkanoates (PHA), and polylactic acid (PLA), have been explored as awareness of these threats and the need for environmental protection has grown (Chen at al. 2017) [6]. The family of polyhydroxyalkanoates (PHA) is one of these bio-sourced and biodegradable polymers that has recently received more attention (Rai et al. 2011; Sudesh et al. 2000; Vroman & Tighzert 2009) [7]. Numerous bacteria manufacture PHA as intracellular carbon or energy stores in the natural environment (Chardron et al. 2010; Dufresne & Samain 1998) [8]. They are considered entirely biosynthetic, biodegradable, and recyclable into organic waste with no hazardous materials. Additionally, they are widely known for having strong biocompatibility, which makes them desirable as biomaterials. Because many soil-based microorganisms can produce PHA depolymerases, which hydrolyze the polymer ester bonds, PHA is effectively broken down in the environment. The breakdown products are subsequently converted by microorganisms into the water and carbon dioxide (Sridewi et al. 2006; Volova et al. 2010) [9]. With more than 150 types of monomer composition, PHAs are one of the most interesting and significant categories of bio-polyesters and produce polymers with adjustable characteristics and possible uses. However, there are only a few PHAs that are commercially accessible. The industrially manufactured PHAs include polyhydroxy butyrate (PHB), poly (3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV), and poly(3-hydroxybutyrate-co-3-hydroxyhexanoate) (PHBH) (Chanprateep 2010) [10]. The most common members of this class are poly(3-hydroxybutyrate) (PHB) and its copolymers with 3-hydroxyvalerate (PHBV) (Kai et al. 2005) [11]. These PHAs are semicrystalline polyesters that can undergo crystallization in different processing conditions. PHBV copolymers show the unique characteristic of cocrystallization despite the variations in repeat unit size. In other words, the crystalline unit cell contains both HV units and HB units (Reinsch & Kelley 1997) [12]. Given this fact, PHAs have certain disadvantages, most notably a high price and limited productivity, as well as a relatively slow crystallization rate due to the unusual chain arrangement (Wang et al. 2022) [13]. Poor mechanical qualities are caused by large spherulite size and secondary crystallization, which restricts the use of PHAs. Therefore, enhancing PHB and PHBV's crystalline characteristics has significant scientific and commercial implications (Wang et al. 2022) [14]. Although PHB and PHBV's structure, nucleation characteristics, thermal properties and processing have been covered in various studies (Sato et al. 2004; Sorrentino et al. 2007; Xu et al. 2018) [15], it is still required to investigate PHB and PHBV's crystallization in order to enhance processing capabilities and speed up the application.

In this work, the crystallization behaviour of PHB and PHBV (featuring 2% valerate content) was investigated at different cooling rates to evaluate the effect of cooling rate on the degree of crystallinity of PHAs. A differential scanning calorimeter (DSC) was used in this study to examine the crystallization behaviour of PHB and PHBV. The Avrami equation was used to characterize the dependency of the relative degree of crystallization on time during nonisothermal crystallization.

## Experimental Section

*Materials*

In this work, two commercial PHAs, namely PHB (Y3000P) and PHBV (Y1000P), were investigated. PHB and PHBV pellets containing 2 % valerate content were purchased from Helian Polymers BV, Netherlands.

*Methodology*

During nonisothermal crystallization from the melt, a DSC Q20 V24.11 Build 124 differential scanning calorimeter (DSC) was used to record the heat transfer rate from the sample and detect temperature changes. The sample weight was kept within the 5–18 mg range. The PHB and PHBV samples were heated from room temperature to 190 °C at a heating rate of 20 °C/min and then cooled the samples to -70 °C at three different cooling rate ranges from 5 °C/min -50 °C/min and again heated to 190 °C. For another processing condition, PHB and PHBV, samples were heated from room temperature to 200 °C and held for 3 min at a heating rate of 20 °C/min and then cooled the samples to -70 °C at three different cooling rate ranges from 5 °C/min -50 °C/min and again heated to 200 °C and hold for 3 min.

## Results and Discussion

Figure 1 shows the crystallization exotherms for PHB and PHBV at three cooling rates and two different processing conditions. It is clear that as the cooling rates are increased, exothermic peaks broaden and move to lower temperatures for both processing conditions. This demonstrates that at slow cooling rates, nuclei can be activated at higher temperatures because they can get enough time, but with higher cooling rates, nuclei can be activated at lower temperatures. When cooling occurs slowly, polymers have more time to crystallize and form large crystals, but when cooling occurs quickly, crystal defects cause some empty space to appear in the crystal. In general, all systems under investigation support this finding. The characteristic information of PHB and PHBV at two processing conditions is gathered in

, together with the degrees of crystallinity, $X_c$, and crystallization temperatures (the temperature at the greatest crystallization peak). It was observed that when the rate of cooling increased, the crystallization temperatures of PHB and PHBV dropped. Additionally, the degree of crystallinity of PHB decreased by 13.39 %, and the degree of crystallinity of PHBV decreased by 16.97% when the cooling rate was increased from 5 °C/min to 50 °C/min and when heated up to 190 °C. Also, the degree of crystallinity of PHB decreased by 15.39 %, and the degree of crystallinity of PHBV decreased by 14.40 % when the cooling rate was increased from 5 °C/min to 50 °C/min and when heated up to 200 °C and hold for 3 min. The presence of 3-hydroxy valerate in PHBV also affects its thermal stability and influences its degree of crystallinity, which could explain the lower decrease in the degree of crystallinity compared to PHB. This highlights the importance of controlling the cooling rate during the processing of these polymers to ensure the desired degree of crystallinity is achieved.

*Degree of Crystallinity*

The heat of crystallization, $\Delta H_c$, divided by the heat of crystallization of a theoretically perfect crystal, $\Delta H_m^0$ of the same substance gives the degree of crystallinity, $X_c$, which is measured during crystallization. The heat of the crystallization of a perfect PHB crystal was calculated using a value of 130 J/g (Scandola et al. 1992) [16], and the heat of the crystallization of a perfect PHBV crystal was calculated using a value of 146.6 J/g (Shan et al. 2011) [17].

*Nonisothermal crystallization kinetics*

The plot of relative crystallinity versus temperature curves for PHB and PHBV are shown in Figure 2, and the relative crystallinity versus time curves for PHB and PHBV are shown in Figure 3 for both processing conditions. From the earliest phases of crystallization to extremely high relative crystallinity values, the linearity of these dependencies is maintained.

## Conclusion

In this study, the physicochemical characteristics of commercial PHAs have been described. Neat PHB and PHBV both exhibit a shift in the crystallization peak to a lower temperature with an increased cooling rate. Moreover, it was found that PHBV has less crystallinity than PHB, which is a result of the structure's valerate content. Due to the introduction of more flexible segments into the polymer chain, a higher valerate content often results in a decrease in the degree of crystallinity, which might hinder the orderly packing of the polymer chains during crystallization. This may lead to lower crystallinity and a more disordered crystal structure.

# Strategy models for upcycling. How to create a systemic change through practice potentialities

**R. Nastasi[a], G. Proietti[a], C. Marino[a], C. Remondino[a]**
a) Politecnico di Torino, Turin, Italy

**Keywords**: Upcycling models, Fashion system, Systemic Innovation Design, Sustainability.

**Abstract**: Upcycling has accelerated considerably during the pandemic, where excess inventories for the spring/summer 2020 collection exceeded 140 billion and are increasingly being explored worldwide (Chan, 2020). The practice involves recycling waste materials of various kinds, intending to make products that are not only sustainable but that, through an appropriate design process, acquire added value compared to the source materials. Applying a specific forma mentis - systemic design - the contribution explores new realities explicitly shaped to be part of the re-fashion sector, established companies that have started in their attempts to reconvert even a part of their system, and aims to define a framework starting from waste to levels of integration of the latter in parallel supply chains. In this case, the Systemic Innovation Design approach represents a methodological approach (Barbero & Tamborrini, 2015) and a sustainable design practice to apply knowledge to systemic problems with the aims of co-designing products, systems and business models for sustainable services (Jones, 2014). Cases of this kind were collected and analyzed to capture and return the salient aspects of each upcycling process. A tripartite form was drawn up with three criteria: sustainability, communication and the intrinsic emotions that the brand wants to convey to the consumer in its upcycling model. The research shows that although upcycling does not yet have a precise connotation (Cassidy & Han, 2015), it is a widespread phenomenon continuously being experimented with by both individual consumers and brands. The contribution attempts to offer a critical overview of some of the realities currently on the market and to highlight how, from the same practice, completely different business models can emerge.

## Introduction

The fashion industry is a large-scale economic sector. McKinsey's report estimates that comparing this industry's revenue to the single countries' GDPs, it would be ranked as the seventh-world economic power (McKinsey, 2016). Such a big industry indeed has a great environmental impact. It is, in fact, reported that in 2015 the fashion industry consumed 79 billion cubic meters of water, has emitted 1715 tons of $CO_2$ and 92 million tons of waste of various kinds. It has been estimated that, at this rate of growth, these figures are going to double by 2030 (European report, 2019).

Before 2020 the industry's total revenue was between 1,7 and 2,5 trillion dollars. (McKinsey, 2020). The Covid 19 pandemic forced the world to stop and rethink how to approach goods production. This new scenario can be described with the term New Normal, meaning a situation where routines are disrupted, and the extraordinary becomes ordinary (Sacchi, 2020). This global change indeed touched the fashion industry. It has been estimated that the "excess inventory from spring/summer 2020 collections were more than double the average", with a total value between €140 billion to €160 billion (Chan, 2020). This deadstock provided the opportunity to experiment with sustainable ways of doing business.

In recent years entrepreneurs are reflecting on the "excessive speed that has not translated into positive change or evolution" (Sacchi, 2020); it follows that the new requirement for goods is high durability. In the fashion field, words such as seasonless, timeless and carry-over appear (Sacchi, 2020). New studies have also shown that buyers are gradually more aware of their actions and choices. They can now be defined as active subjects, overturning the most important economic theories of the last century (Sacchi, 2020).

In addition to the challenges brought by the pandemic, the industry is now facing the consequences of geopolitical instability and inflation. Therefore, the general expectations are pessimistic despite the recovery in 2021 and part of 2022. Two-thirds of the executives are considering nearshoring to mitigate the effects of inflation and the possibility of disruptions in the supply chain. In addition, 75% of executives want to reduce their inventory, and 16% think implementing sustainability represents a significant market opportunity (McKinsey, 2022).

All the previous premises suggest that it could be the right time to work on alternative ways of conceiving businesses. A profitable direction could be a business model based on tackling the massive amount of waste the industry produces, slowing manufacturing processes, considering the consumers' newfound critical voice and resisting geopolitical fluctuations. The upcycling technique, "to treat an item that has already been used in such a way that you make something of greater quality or value than the original" (Oxford Advanced Learner's Dictionary), could be an effective way to satisfy all the previous requirements.

This contribution intends to provide general guidelines for creating a sustainable upcycling strategy in the fashion field. After a detailed analysis of the fashion scenario and the post-pandemic tendencies, the research focuses on finding a theoretical foundation for sustainable upcycling businesses by defining three main criteria: sustainability, communication and emotions. Lastly, in addition to the guidelines, the paper outlines a general system as a base for constructing a sustainable upcycling model.

## Methodology

Upcycling has had considerable experience in the fashion industry, so it was necessary to analyse what has already been done in this field. Firstly, it was essential to define a suitable method for collecting data, outlining companies' systems and identifying their strengths and weaknesses.

### *Definition of parameters*

Considering the scenario, it is necessary to pay attention to the sustainability of companies and the proper development of communication. However, we also wanted to analyse the human dimension during this work. Indeed, emotions constitute an immutable constant that evolves but does not disappear throughout people's lives.

**Sustainability** is not only about the environment. Designing a production system "means meeting our needs without compromising the ability of future generations to meet their own needs" (UN Brundtland Commission, 1987); therefore, social rights and economic development are crucial aspects to consider.

**Communication** encompasses what a brand decides to tell about itself. Through the tone of voice, a company uses for its storytelling and the choice of verbal or iconic language, it is possible to generate specific imagery and successfully engage the right target audience.
Finally, **emotions** are the most underestimated criterion yet the most crucial element in creating consumer affection.

### *How parameters work*

Parameters are meant to work together symbiotically with the right balance. Each element must exist apart from the other but must be present and structural. In our analysis, Sustainability, Communication, and Emotions are equally important (Figure 1).

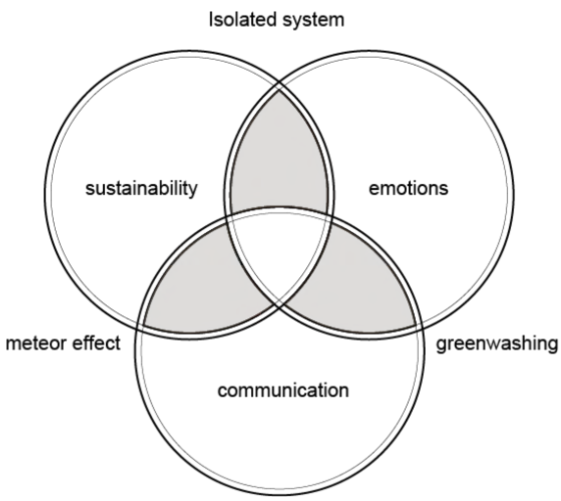

**Figure 1. Functioning of parameters and intersections.**

When sustainability is not involved, businesses tend to incur "behaviour or activities that make people believe that a company is doing more to protect the environment than it is" (Cambridge Advanced Learner's Dictionary & Thesaurus, n.d.). This phenomenon is known as Greenwashing: the user is hooked by a well-crafted communication strategy based on sustainability. However, as soon as the fraud arises, his affection will undoubtedly become outraged.

When Communication is missing, a business cannot reach out to the masses despite noble intentions. Therefore it is destined to create an isolated system and be confined to a small niche.

When Emotions are excluded, Communication and Sustainability must engage more with the consumer, and the business will be able to stand out among its competitors.

*Case studies' analysis*

These parameters constitute the structure for the case studies analysis, which explores brands' systems, focusing on every element involved in reaching success in the upcycled fashion industry.

Every case study is introduced by a text providing basic information (who founded the brand, when and where, the category of items it sells, and the mission). Then, a radar scheme reports the influence of each parameter (Figure 2). It uses three axes, one for each variable: it is assigned a score of 0 to 5 to each value, assuming 0 as "not at all" and five as "completely": thus, assigning an objective rate based on deep analysis; it generates a triangle, through whose shape it is possible to summarize the trend of the brand.

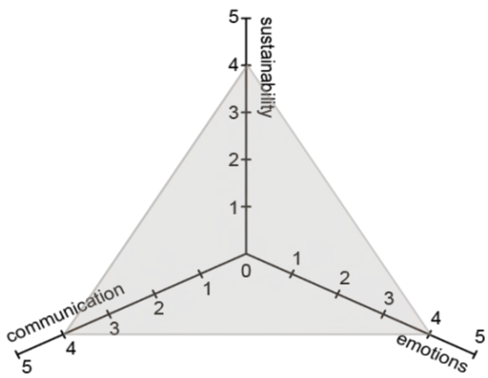

**Figure 2. Radar scheme (with an hypothesis of the triangle generated after the evaluation).**

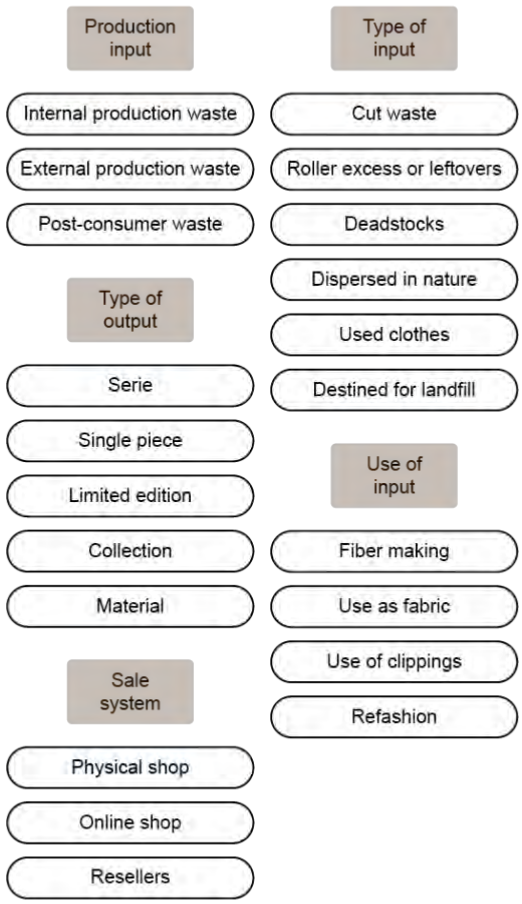

**Figure 3. Evaluation tags for Sustainability.**

The sustainability part uses tags to define the inputs adopted and the outputs produced (Figure 3). The central part is the visual reproduction of the business' system (from sourcing raw material to selling the final product and, where possible, to post-consumption or disposal).

**Figure 4. Evaluation tags for Communication.**

The Communication part reclaims tone of voice parameters studied by Valentina Falcinelli in "Testi che parlano" (Falcinelli, 2018), and again, thanks to simple tags, it defines both visual and verbal languages adopted (Figure 4).

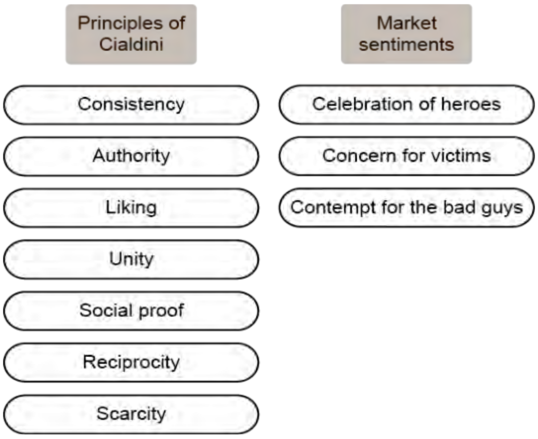

**Figure 5. Evaluation tags for Emotions.**

**Figure 6. Emotions' evaluator from Plutchick's Wheel of Emotions.**

Finally, emotions are described by the Market Sentiments, the Principles of Persuasion by Roberto Cialdini (Cialdini,2007) (Figure 5) and an evaluator inspired by Plutchick's Wheel of Emotions (Plutchick, 1991) (Figure 6). In this case, businesses must be studied on two levels: the first analyzes the feelings the brand is trying to recall, and the second one tries to understand what final users receive.

The review of each brand must consider the target too. For that, it has been used a division based on generations (Figure 7).

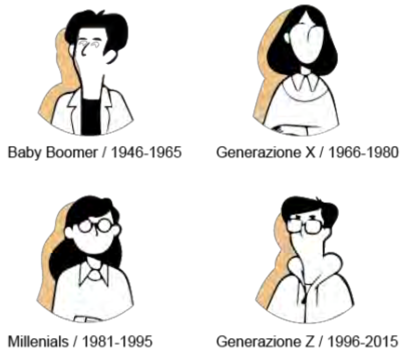

**Figure 7. Division based on generations.**

Many recent sociological studies have shown that distinctive features developed in relation to the historical period in which one grew up that unite groups of people belonging to the same generation. It cannot precisely describe the target of the brand; anyhow, it allows us to identify the age range of the final users and their vision of the world (Istat, 2016

## Findings

As a result of deep research in upcycled fashion, 34 businesses have been selected and analyzed. Most of the cases adopt the upcycling model as the primary production system (Figure 8), which can differ by the type of inputs (Figure 11) and outputs (Figure 9) and the type of production (Figure 10).
All the cases are actual functioning companies from all over the world (Figure 14).

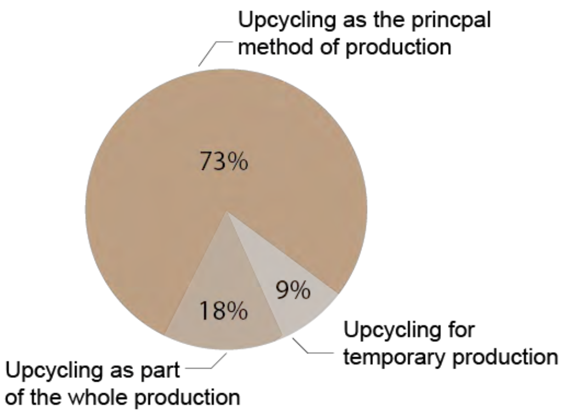

**Figure 8. Upcycling as the main core business versus upcycling for exceptions (referred to the 34 cases).**

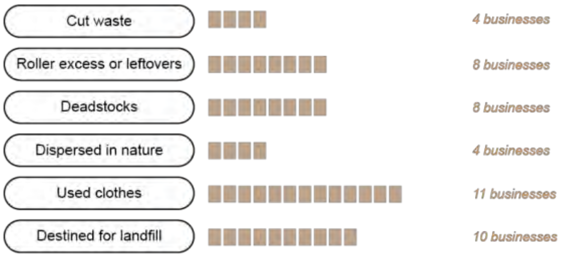

**Figure 9. Inputs the 34 businesses adopt.**

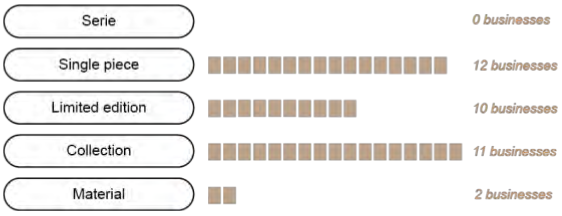

**Figure 10. Outputs the 34 businesses produce.**

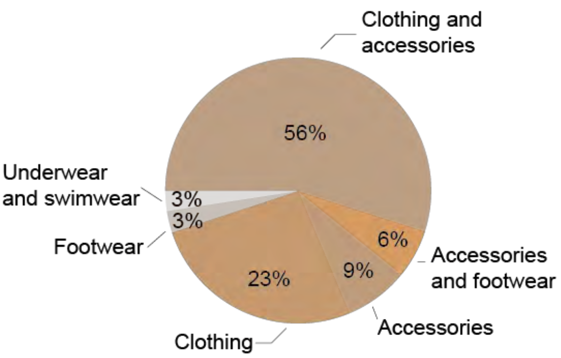

**Figure 11. Type of production of the 34 cases analyzed.**

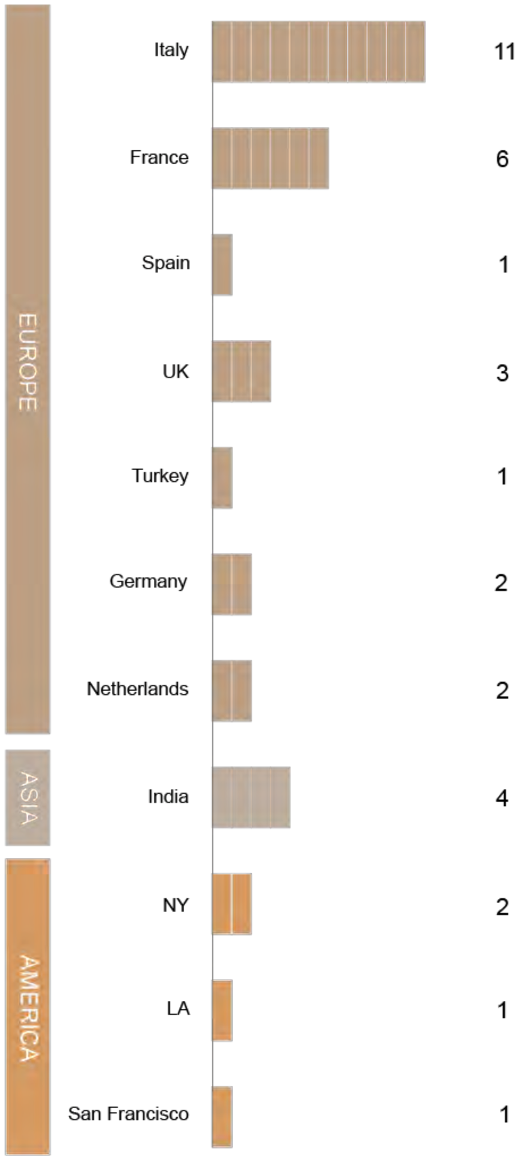

**Figure 12. Cases analyzed (referred to the 34 cases).**

**Figure 13. Cases analyzed by dimension (referred to the 34 cases).**

The analysis shows that only a small percentage is balanced (or semi-balanced) according to the tripartite scheme. In particular, this percentage is composed of medium-small companies (Figure 15) with a clear target and strongly independent from the fashion market trends. All the other brands considered, on the contrary, manifest a strong imbalance towards one of the parameters (Figure 16).

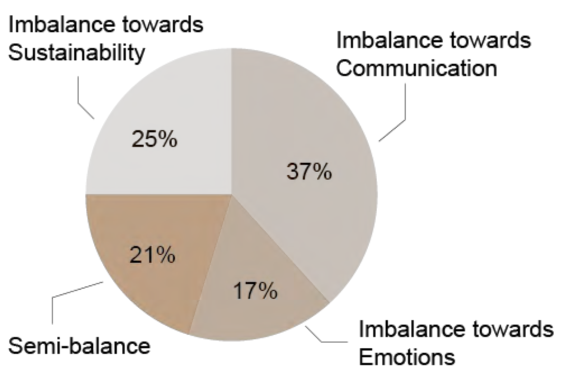

**Figure 14. Analysis of businesses' results.**

Thus, a categorization based on the weight of a specific parameter guides the identification of four groups.

*Imbalance towards Sustainability*

Cases included are niche businesses with highly-specialized productions, with a defined type of inputs and outputs. Moreover, they refer to a defined target, apparently not contemplating enlargements because of undeveloped communication strategies (Table 1).

| % of the category | Properties and characteristics |
|---|---|
| 28,6 | Very high level of sustainability<br>Absence of balance on the triangle<br>Niche businesses |
| 64,3 | High level of sustainability<br>Imbalance on the triangle<br>Niche businesses: strong specialization of the production |
| 7,1 | Medium level of sustainability<br>2 parameters balanced on the triangle<br>Niche businesses: poor communication |

**Table 1. Imbalance towards Sustainability's data.**

*Imbalance towards Communication*

Cases included involve some of the most famous brands in the fashion industry: whether it is a coincidence or not, it is always about limited editions or temporary collaborations. Furthermore, data confirm that these actions mainly aim at trends and market needs (Table 2).

| % of the category | Properties and characteristics |
|---|---|
| 50,0 | Very high level of communication<br>Significant absence of balance on the triangle<br>Limited edition / temporary collection |
| 50,0 | High level of communication<br>Imbalance of the triangle<br>Limited edition |

**Table 2. Imbalance towards Communication's data.**

*Imbalance towards Emotions*

Cases included are little-known niche business realities. This group involves brands with a very defined production, mainly based on the uniqueness of the items. It is mostly about one-piece outputs attributable to luxury or high fashion (Table 3).

| % of the category | Properties and characteristics |
|---|---|
| 33,3 | High level of emotions<br>Significant absence of balance on the triangle<br>Niche businesses: strong specialization of the production |
| 33,4 | High level of emotions<br>Imbalance on the triangle<br>Niche businesses: on piece |
| 33,3 | Medium level of emotions<br>Imbalance on the triangle<br>Niche businesses: little or unknown brands |

**Table 3. Imbalance towards Emotions' data.**

*Semi-balance*
Cases include primarily designers' actions, who work in their atelier with strong motivations leading to courageous choices in fashion panorama. Also, there is particular care at every step of the system. Each reality has strong specialized production, is constantly improvable, and is transparent in every stage of creation. (Table 4).

| % of the category | Properties and characteristics |
|---|---|
| 30,0 | Balance on the triangle<br>Very defined target<br>Growing businesses |
| 70,0 | Unsignificant imbalance<br>Very defined target<br>Businesses with great chances to grow and improve. |

**Table 4. Semi-balance's data.**

## Guidelines
Despite the existence of a small percentage of successful businesses, not many realities are worthy of becoming a model for aspiring to. Unfortunately, upcycled fashion businesses remain niches known exclusively by some conscious consumers.

A significant problem nowadays is that sustainable business models must consider circularity in their systems. Focusing on inputs and outputs is not enough. Creating raw materials (inputs) and disposing of final objects (outputs) are both very expensive and impactful. Upcycling allows them to downsize their impact, relocate their role inside a production system and, more importantly, convert them into connection points. These stages generate empowering relations among different systems instead of just being the initial and the final phases of a potentially unsustainable process.

*Structural guidelines*
Starting from the criteria covered previously, the research will now focus on defining general guidelines (Table 5) that a sustainable fashion brand that chooses the upcycling technique should follow.

| Guidelines | Description |
|---|---|
| Enhance the history | In order to create real affection with the product, its communication should be created around the waste's history. |
| Phigital district | A sustainable brand should be part of a more complex system, where one business' outputs can become anothers' inputs. These connections should be implemented through digital means. |
| Local supply chain | To maximize sustainability, the supply chain and the production should be limited to a small area. |
| Shared knowhow | A sustainable brand should provide platforms to share knowledge. This way businesses, and ordinary people as well, can be empowered and generate positive impact. |
| High quality's raw material | A sustainable brand should use only high quality's material, so that garments can have a long life cycle |
| Designed end-of-life | To create a circular system, a sustainable brand should design the last part of their products' life, reintroducing them to their system or making sure they are going to enter in others. |

**Table 5. Description of guidelines.**

*System's guidelines*
After defining the guidelines, it is possible to draw a generic system with the fundamental components for a sustainable upcycling brand and its relations. This could represent a base point for more complex business models (Figure 15).

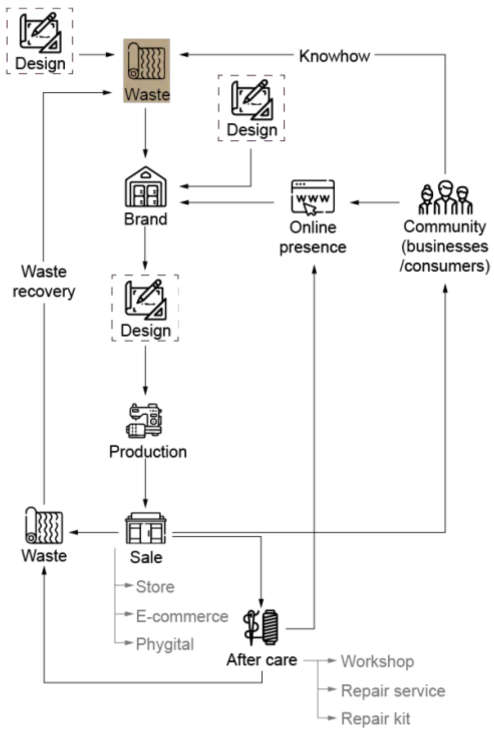

**Figure 15. Processes of general system.**

The process originates from the section "waste," a general definition of the system's inputs. These inputs can be various; the only requirement is that they must not be of new production. The brand then collects the waste.
The "design process" needs special mention. It is possible to see that it is positioned in more than one place because, depending on the brand's business model, this process can occur at different times.

The next step is production, followed by sale, which can be managed physically, digitally or, more effectively, in both ways. Finally, the brand needs an online presence to interact with the community and share and collect know-how.

The final part of the system covers the post-consumer phase. According to the previous guidelines, the products' end-of-life must be designed, and a sustainable brand should predict at least two ways to do so. The first is allowing the consumer to repair or modify the garment to postpone disposal. The second one is designing the path the waste will follow, ensuring it will be reintroduced as an input in a productive system.

## Conclusions
As specified at the beginning of the research, the paper aims to provide strategies and best practices to businesses that aim to be sustainable. The three parameters represent a dual resource for designers, giving them both a structural direction and a toolkit to draw from for innovation.

According to the scenario outlined, times are favourable for introducing new sustainable production models, and upcycling is an optimal solution. Adopting the practice as the primary production strategy would allow businesses to think from a systemic perspective and to find opportunities in what now is seen as a waste. To achieve higher levels of sustainability, companies should no longer perceive themselves as separate entities from the surrounding environment, but they should aim to connect their systems to existing ones. Implementing the right connections is crucial.

This research's findings report that this mindset is already present in many businesses but is too often confined to the input phase. There are, in fact, multiple examples of the different ways a business can source leftover fabrics, but not many models suggest how to tackle the post-production and post-consumer waste generated by their systems. This unexplored area could be a breeding ground for innovation for designers looking for effective and unprecedented solutions to "close the circle".

*Research's limits and future goals*
This research takes a systemic design perspective; its aim is not to provide detailed production techniques but to analyse and suggest flow management strategies and provide insights to innovate the fashion industry.

The three parameters result from an analysis that places humans at the centre before any other element; however, it is, of course, just one of the many possible ways to provide an innovative and sustainable point of view.

Furthermore, the cataloguing based on these parameters uses evaluation tools supported by literature or, in some cases, based on qualitative criteria. The goal is to refine the method to implement the analysis's objectivity, involving the analyser's subjective aspect as little as possible.

Finally, although, at the moment, this research is only theoretical, the next step would be to apply the system and guidelines and test them empirically.

# Wearer-clothing Relationships as a System (and where to intervene)

**Neto, Ana**[(a)]
a) CIAUD, Research Centre for Architecture, Urbanism and Design, Lisbon School of Architecture, Universidade de Lisboa, Rua Sá Nogueira, Polo Universitário do Alto da Ajuda, 1349-063 Lisboa, Portugal

**Keywords**: Wearer-clothing relationships; Systems thinking; Fashion sustainability; Clothing consumption; Use phase.

**Abstract**: This paper introduces wearer-clothing relationships as a system, to understand how their longevity (and thus, the longevity of garments) interrelates with larger systems such as the wardrobe and clothing consumption. Keeping clothes in use for longer contributes to reducing their carbon footprint and constitutes one of the pathways needed to align clothing consumption with climate neutrality goals. What drives wearers to do so is difficult to generalize, as their relationship with clothes is complex, emotional, and idiosyncratic. It is therefore imperative to understand the intricacies that make-or-break these relationships. In previous research, I explored what happens between wearers and their clothes in the light of theories on love and interpersonal relationships. Now, I revisit those findings in the light of Donella Meadows' "Thinking in Systems" (2008) and present a systemic view of wearer-clothing relationships, to better understand and explain what makes them last.

The map presented in this paper highlights that intervention in this system should aim at nurturing resilience mechanisms, which absorb and adapt to the shock of conflict and contribute to relationship longevity. Additionally, it draws attention to the importance of reducing or delaying conflict, to buy the system time to develop resilience. Further to this point, the systemic view of wearer-clothing relationships allows us to understand how different business models promoting clothing circulation can undermine the context for relationship building and nurturing. Due to its potential for slowing down wardrobe inflows and outflows, wearer-clothing relationships should be carefully considered in initiatives intended to counteract clothing overconsumption and waste.

## Introduction

Garment overproduction and fashion media stimulus are indisputably associated with more clothes being bought, used less, and discarded prematurely, in a scale of overconsumption which constitutes a real environmental threat; people need to use their clothes for longer to reduce their carbon footprint and contribute to align fashion consumption with climate neutrality goals (Ellen MacArthur Foundation, 2017; House of Commons Environmental Audit Committee, 2019; Niinimäki et al., 2020; Denisova, 2021; Coscieme et al., 2022).

In this scenario, circular consumption models are being offered as a way to capture the monetary value of underutilized clothes: as such, rental and resale shine as business opportunities to keep clothes in circulation, attractively offering flexibility and choice (Ellen MacArthur Foundation, 2017; WRAP, 2020), hyped on the freedom of consumers to enjoy new(-to-them) clothes more frequently. However, the resulting speed of circulation disrupts the very nature of the bonds between wearers and clothes (Choufan, 2021). Several wardrobe studies bear witness to wearers' will and ability to keep wearing their clothes for a long time (e.g., Woodward, 2007; Niinimäki & Koskinen, 2011; Fletcher, 2016; Burcikova, 2019; Laitala & Klepp, 2020), even though the amount of factors at play – related to owner, garment and context – makes it difficult to generalize on what drives them to do so; people's relationship with clothes is complex, emotional, and idiosyncratic. Ezio Manzini explains that while we cannot design relationships, we can design for relationships, which is to design for a context that affords relationship building and nurturing (Fayard, 2023). It is therefore imperative to understand the intricacies that make-or-break wearer-clothing relationships.

In previous research, I explored what happens between wearers and their clothes in the light of theories on love and interpersonal relationships. I have argued that love – that is, the passion, intimacy, and commitment the wearer feels towards the garment – is foundational for these relationships and develops through positive experiences of wear and care; moreover, love takes time to develop, and negative experiences (conflict situations) can gradually or abruptly deteriorate a relationship (Neto & Ferreira, 2020). After all, love involves vulnerability; loving, caring and valuing something implies being susceptible to its distress, harm, loss, or damage. And the greater these feelings, the greater the vulnerability (Tsai, 2016).

And yet, I have also observed that conflict does not necessarily result in relationship deterioration or garment disposal: it is the will and skill of the wearer to overcome conflict that is paramount to relationship longevity (Neto & Ferreira, 2021). Wearing and caring, appreciating and constantly learning about the garment generates the buffers the relationship needs to successfully survive conflict. In a resilient relationship, the building of memories (meaning) and reliance can contribute to an emotional durability which does not compromise continuous wear and care (Neto & Ferreira, 2023).

In this exploratory paper, I revisit those findings in the light of Donella Meadows' "Thinking in Systems" (2008) and present a systemic view of wearer-clothing relationships, to understand how their longevity (and thus, the longevity of garments) interrelates with larger systems such as the wardrobe and clothing consumption.

## Theoretical Framework

Systems thinker Donella Meadows defines a system as "an interconnected set of elements that is coherently organized in a way that achieves something" (2008, p.11). As such, elements interconnect to respond to a purpose, which is the most important determinant of a system's behaviour. To understand their behaviour over time, systems are mapped through their structure: the stock (the system's foundation) and inflows and outflows which regulate said stock. Stocks change in response to flows, which in turn change in response to stocks or external elements. This is because no system lives in a vacuum and the connection with other systems makes it susceptible to external forces. As such, mapping a system helps to clarify its resilience mechanisms, that is, the diverse ways it finds to survive and persist through external shock. However, it also implies defining artificial boundaries (i.e., when mapping through a diagram) that best fit the purpose of the discussion.

Systems thinking "is a way of thinking that gives us the freedom to identify root causes of problems and see new opportunities" (Meadows, 2008, p.2); it allows us to find areas where we can intervene to make the system do more of one thing and/or less of another without undermining its capacity to maintain itself.

The use of systems thinking related to clothing use is not new. Maldini and Stappers (2019), for example, contributed to understanding the dynamics of clothing consumption by mapping the wardrobe as a system, which is admittedly challenging to control; noting that inflows and outflows of clothing in the wardrobe can occur independently, they explain that each item in the wardrobe responds to "very specific sets of purposes, which can change over time and in relation to other items" (p.20), and that the discrepancy between the purposes of the wardrobe and the purposes of the clothes influence the inflow and outflow of items.

In this paper, the systems perspective is used to better understand and explain wearer-clothing relationships, where love is the foundational product (or stock) of the interactions between wearers and their garments. The feeling of love for clothes goes frequently unrecognized by wearers, and although its presence is acknowledged in research, it has remained underexplored. Love is intangible and hard to measure, but I follow Meadows' advice to mind what is important, and not only what is quantifiable: "if systems aren't designed to produce [values such as love], if we don't speak about them and point toward their presence, they will cease to exist" (2008, p.177). It is by considering the crucial role of love that we shift the understanding of a wearer-clothing relationship of dominance (consumption) to a relationship of care (Ehrenfeld & Hoffman, 2013).

## Wearer-clothing relationships as a System

In wearer-clothing relationships, wearer and garment are interconnected through experiences of wear and care. Each positive interaction results in the build-up of love. In turn, love reinforces the willingness to go on wearing and caring.

The purposes in these relationships are not absolute, but rather perceived by the individual. A wearer's purpose of building an identity and feeling ready for each occasion (e.g., warm, comfortable, confident, strong, young, free, safe) demands from the garment more than its function of being worn. Designers can imprint functions in garments through physical attributes (e.g., padded shoulders to provide a formal look, a generous cleavage to facilitate nursing), but the wearer's purpose for that garment can challenge all that and ultimately influence the course and endurance of the relationship.

Alice, a respondent from previous research, had a T-shirt that she was rarely using due to fear of ruining it, as it had become a memory of an event she and her brother enjoyed together. Notice how the event transformed the relationship between wearer and garment into one between a memory holder (person) and memory trigger (t-shirt). An external factor altered the purposes of each element of the relationship and their interactions, now hindering the wearer-clothing relationship: Alice now had one less T-shirt available in her wardrobe.

The fateful event illustrates one of the plethora of ways in which external factors trigger, drive, hinder and constrain the interactions between wearer and garment: consider the impact of fashion businesses and social media, family and friends, laundry facilities and daily circumstances, and even newer garments in the wardrobe. The vulnerability that comes with one's love for a garment gives way to conflicting external forces, which arise from the interaction of many other systems with wearer-clothing relationships.

Conflict can have a double effect on the relationship: a negative experience can make the wearer less passionate about, intimate with or committed to the garment (and thus trigger the loss of love), and therefore make the wearer less willing to interact further with the item (and thus hinder future practices of wear and care). The fear of a negative experience can have a similarly conflicting effect, as in the case of Alice and her T-shirt above.

In Figure 1 we can see love has the power to reinforce wear and care for the garment (dashed arrow marked with an R), whereas conflict has the power to generate a double impact (dashed arrows marked with a B). This explains the stronger weight of negative experiences over positive ones. The little clouds mark the borders of the mapping proposed in this paper.

Conflict can gradually deteriorate a relationship, or quickly deplete the love in it (Neto & Ferreira, 2020), but that is not always the case (Neto & Ferreira, 2021). It turns out, wearer-clothing relationships can, too, be resilient systems.

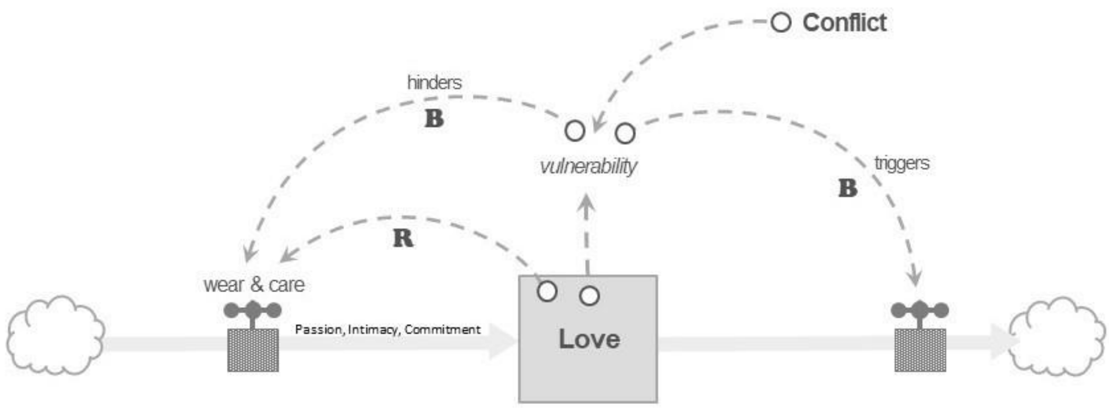

**Figure 1. Understanding love and conflict in wearer-clothing relationships.**

In wearer-clothing relationships, resilience develops as a capacity to mitigate the impact of shock and adapt to its consequences.

Firstly, the relationship can benefit from two buffers (Figure 2).

1) Positive Perspective, when the wearer can see the garment in a good light during mishaps, which overrides the negative feelings of the conflict (Neto & Ferreira, 2023). Therefore, developing a positive perspective enables the relationship to withstand the shock of conflict.

2) Love Maps, when the wearer knows and keeps learning how to wear and care of their garment (Neto & Ferreira, 2023), which provides the wisdom and resourcefulness to mitigate and cope with conflicts. Knowledge here is not limited to how to mend, but where to get the right mending supplies or where to get it mended; it is not limited to wear in tried-and-true conditions, but also coming up with a different outfit to wear for an unexpected context); not limited to knowing, but knowing where to turn to know, developing the skill to figure it out. Keeping a love map of the garment makes the relationship adaptable to the change that results from conflicts.

Both buffers (positive perspective and love maps) build from wear and care, but we understand how they can develop additionally, through the ability and habit of the wearer to appreciate the garment and their relationship (to see), and to keep learning about the garment beyond physical interaction (to learn). These buffers constitute the shock-absorbing mechanism of the relationship and mitigate the impact of conflict. Further, they contribute to the will and skill to successfully manage conflict, which works as the emergency-response mechanism of this system. The positive perspective contributes to the willingness to overcome it, while love maps (knowing how to wear and care) contribute to the skill to manage conflict. Moreover, these buffers promote further engagement between wearer and garment – a beneficial redundancy to stimulate wear and care, as multiplying ways to nurture and strengthen love builds resilience to conflict.

Notice that, in this resilient environment, two other “side effects” of love can flourish and be sustained: meaning and reliance. These effects, in turn, invite further wear and care for the garment. Here, the wearer can garner memories of lived experiences with the item, and count on it as an ally for future adventures.

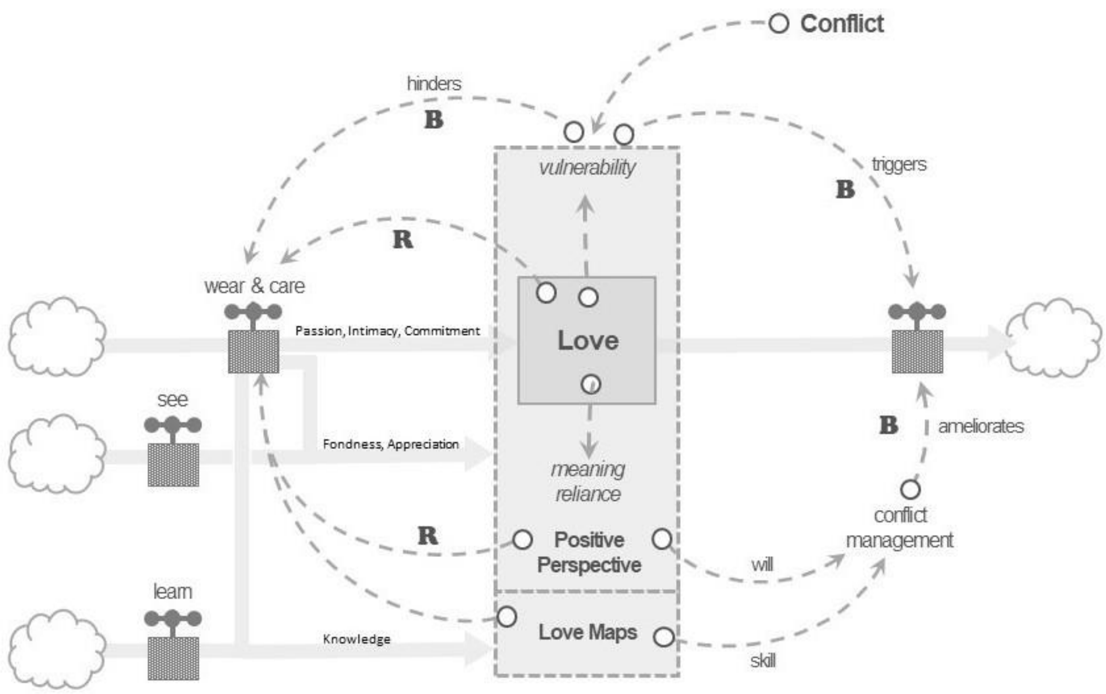

**Figure 2. A systemic map of wearer-clothing relationships.**

Additionally, such environment promotes flexibility in the purposes the wearer bestows upon their garment (frequently perceived as high versatility in clothing), which can contribute to bridge the gap between the purposes of each item in the wardrobe, and the purposes of the wardrobe at large.

To stimulate love and resilience in wearer-clothing relationships, intervention should concern promoting wear and care, but also nudging the wearer into exercising appreciation and keeping updated on the garment. Bear in mind that interventions are relationship-specific: appreciating the wardrobe differs from appreciating each garment; general laundering or mending advice varies from specific support on caring for a specific garment before or after trouble. Little by little, interventions can strengthen specific wearer-clothing relationships and enhance their self-sustaining abilities, and additionally nurture a caring mindset to spread throughout wearers' general approach to clothing.

## Discussion

Understanding wearer-clothing relationships as relationships of love enables us to discern a system that supports fashion activity beyond the boundaries of consumption.

Systemic mapping can reveal crucial aspects of these relationships. For instance, the love that develops from people's experience with their clothes entails vulnerability; and conflict can deteriorate a wearer-clothing relationship or have little effect if the relationship is resilient. But if wearer-clothing relationships can develop resilience, why are there so many failed relationships turned to textile waste?

Resilience, like love, takes time to develop. If conflict happens before the system is able to deal with it, the relationship faces a severe impact and likely ends. While we cannot eradicate conflict, we can consider ways to mitigate or postpone it. Consider the design of garments for physical durability: it could seem like a waste of energy, as no garment is indestructible – conflict will occur, and a single occurrence can end a relationship. However, quality garments can decrease the chances of premature conflict. While the map presented in this paper highlights that intervention in the system should aim at nurturing resilience mechanisms – which absorb and adapt to the shock of conflict and contribute to relationship longevity – it also points to the importance of reducing or delaying conflict, to buy the system time to build love and the buffers which are paramount to develop resilience.

Accordingly, the significance of reducing production volumes and limiting fashion advertising to mitigate and delay conflict between wearers and their clothes is clear: abundantly available unexpensive fashion, together with advertising and media discourse, stimulate the craving for new clothes at the expense of already owned items, as frequent purchases conflict with the wearer's relationship with other items in the wardrobe by hindering their use and triggering disposal.

Through the systemic view of wearer-clothing relationships, we notice how other business models promoting clothing circulation can similarly destabilize the context for relationship building and nurturing: For example, online platforms facilitating peer-to-peer trade of used clothes contribute to keeping textiles out of the waste stream; however, if they drive quicker turnovers in the wardrobe, they are contributing to the fleetingness of wearer-clothing relationships and the de-skilling of wearers on how to nurture a relationship with their clothes. In addition, rental services keep clothing in circulation by facilitating "no-strings attached" relationships with clothes; while these may not be conflict-free, such services provide an easy way out, which rids the wearer of the vulnerability and effort that come with a relationship with clothing. When these consumption alternatives exploit the desire for frequent outfit changes, they are encouraging a careless mindset of using up and letting go rather than a mindful engagement with clothing. Therefore, any clothing-related initiative (product, service, education or policy-based) should consider its impact on individual wearer-clothing relationships – whether they strengthen or undermine the resilience of these relationships.

While clothing retention does not necessarily stop future purchases, stronger relationships with clothes enable the flexibility of purposes of each item. As such, the gap between each item's purpose and the wardrobe's purpose can be shaped into affinity, and a reduced

discrepancy in purposes can slowdown wardrobe inflow.
In sum, current efforts to halt clothing overconsumption and waste can benefit from taking heed to love in wearer-clothing relationships.

## Acknowledgments

I would like to thank João Ferreira and Irene Maldini, for their valuable comments and editing suggestions on earlier versions of this paper.

# Transforming sustainable business as usual: A tool encouraging businesses to go further

**Niessen, Laura[(a)], Bocken, Nancy[(a,b)]**
a) Maastricht Sustainability Institute, Maastricht University, P.O. Box 616, 6200, MD, Maastricht, the Netherlands
b) International Institute for Industrial Environmental Economics (IIIEE), Lund University, Tegnérplatsen 4, Lund, Sweden

**Keywords**: Sustainable business; Business tools; Serious games; Flourishing.

**Abstract**: Through our systems of production and consumption, we have already surpassed several planetary boundaries. Therefore, far-reaching transformations are required to ensure that human activity returns into the limits of planetary carrying capacity. For business, these transformations imply moving beyond the status quo and reorienting business activities by fully integrating environmental and social concerns. Business (model) tools can drive business innovation towards such integrated sustainability. While tools for sustainable value creation and circularity exist, they do not yet stimulate companies to look beyond and are missing a vision towards which businesses should be working. Therefore, we developed a prototype for The Road Ahead, a business tool in the form of a board game that aims to encourage advanced sustainability actions. Based on a diagram showing the hierarchy of Sustainable Business Models, the game takes players through to the next steps, moving from business action on efficiency, over net zero, circularity and sufficiency, towards regeneration and flourishing. The interactive quiz nature of the board game is intended to provide information at the same time as questioning players' assumptions by showing what more can be done. The tool is developed to be of short duration and combinable with existing tools, to provide a goal post in business innovation sessions to measure current and future sustainability ambitions. In the next steps, will be reviewed and tested to ensure that it meets this objective.

## Introduction

Humanity is living in the age of the Anthropocene (Crutzen & Stoermer, 2000), where patterns of production and consumption directly impact planetary systems. Through current lifestyles, we have surpassed six of the nine planetary boundaries into a zone of uncertainty, including climate change, biodiversity and land system change (Persson et al., 2022; Steffen et al., 2015; Wang-Erlandsson et al., 2022), with implications that we cannot yet ascertain. Far-reaching transformations are required to limit resource extraction and mitigate climate change. While many businesses are working towards more sustainable operations, most focus on efficiency improvements or 'low-hanging fruits', such as supporting the lower levels of the waste hierarchy (Kirchherr et al., 2017). The far-reaching transformations that are required, however, mean that businesses need to move beyond the status quo towards a circular economy that integrates sufficiency, regeneration and flourishing (Bocken et al., 2022). While indispensable for future sustainability, the circular economy is not yet implemented in a way that guarantees sustainability (Velenturf & Purnell, 2021) and concepts going beyond circularity still hold a niche character in the business community.

Business innovation towards sustainability can be promoted by business model (BM) innovation tools. These can take different forms and are supporting materials to help ideate and change business practices. Perhaps the best known tool, the Business Model Canvas (BMC) (Osterwalder & Pigneur, 2010), has been adapted by researchers to include sustainability considerations (Bocken et al., 2013; Jones & Upward, 2014; Joyce & Paquin, 2016). Other tools for sustainable business model development have taken the form of archetypes (Bocken et al., 2014) or typologies (Luedeke-Freund et al., 2019), and tools have been developed to support experimenting with and implementing circular business models (Konietzko et al., 2020). Yet, while these tools provide concrete support for BM innovation, they do not yet provide a vision for business to go beyond circularity and do not explicitly integrate fundamental concepts, such as sufficiency and regeneration (Bocken et al., 2022). Existing tools largely encourage incorporating sustainable value in a business model, but the larger vision of what far-reaching transformations are needed, is missing. Therefore, we asked the question: *How can advanced business sustainability transformations be encouraged with the help of tools?*

Realizing that there is a need not just for more radical tools (e.g., on sufficiency or regenerative business), but also for an overall vision of what lies ahead, we developed an introductory tool that can be combined with others. 'The Road Ahead' is a short-duration tool offering an introductory, low effort way for participants to think beyond their existing understanding of sustainability. Building on the work around serious games, 'The Road Ahead' was realized in the form of a board game, enabling play that transmits serious content in a playful and engaging manner, supporting learning and challenging existing sustainability ambitions. Ultimately, the tool's aim is to create a vision of business sustainability and to showcase to businesses that they can (and should) aim higher on the ladder of sustainability. It is based on the Hierarchy of SBM archetypes visual from Bocken and Short (2021) that identifies flourishing as the intended sustainability outcome, in line with work by Ehrenfeld and Hoffman (2013). Designed as a modular add-on or introduction to a session, it can be easily combined with existing tools and used as an introductory exercise or in-between sessions to review sustainability ambitions.

## Background

While many businesses are working towards sustainability, efforts are often limited to efficiency and productivity improvements, installing renewable energy sources or clean production technologies (Kirchherr et al., 2017). While these can be sustainable business model and are represented in the SBM archetypes (Bocken et al., 2014), these archetypes were intended as complementary and were presented by Bocken and Short (2021) in a hierarchy of archetypes moving towards stronger sustainability: from efficiency over net zero, circularity, sufficiency, net positive towards flourishing. The authors suggest that business and policymakers should "set ambitions to ultimately target solutions at the top of the diagram" (Bocken & Short, 2021, p. 11).

One means of helping businesses innovate and change towards sustainability are business model tools. Tools are used to "support understanding, assessment, creativity and/or change on particular practices" (Velter et al., 2021, p. 3) and have been designed to support the business transformation to circular and sustainable business models. Tools to incorporate sustainability in business models have attempted to include the environment and society as stakeholders or focus on value creation beyond financial profit (e.g., Bocken et al., 2013; Jones & Upward, 2014; Joyce & Paquin, 2016). As discussed, these tools support the ideation and implementation of sustainable business models but do not provide a more advanced understanding of the road ahead towards transformative change. Recently, the Doughnut Design for Business tool was developed, which helps companies review their main structures and identify levers towards a regenerative and distributive economy (Sahan et al., 2022). While this tool provides an overarching vision of business within 'the Doughnut' of planetary boundaries and social well-being (Raworth, 2017), it does not easily work with business model innovation, as it revises business governance, purpose, networks, finance and ownership in a 4-5 hour workshop. Thus, despite encouraging businesses to look at the underlying factors and transform towards strong sustainability, it might be less appealing to business, being time-consuming, less intuitive and not easily combined with BM innovation. Furthermore, it does not yet stimulate companies to question overconsumption and reconsider the need for high resource throughput and does not present concrete business model action towards strong sustainability. Therefore, we decided to develop a games-based tool to combine with what is already there and fill this gap.

Game-based approaches can be useful for collaborative ideation, for instance by "reframing problems from multiple perspectives" and "offer[ing] frameworks for visualizing problems and solutions" (Peters et al., 2020, p. 2). Serious games are stand-alone activities to educate and raise information. They have also been used by organizations in building sustainable operations and can support sustainable product or business model innovation (Whalen & Kijne, 2019). Examples include the Risk&RACE tool (Whalen, 2017; Manshoven & Gillabel, 2021) to support circular economy business model innovation or the Play it forward game to implement sustainability in the design process (Dewulf, 2010). As pointed out by Ouariachi et al. (2018): "The use of serious games […] has proven to have potential as a way of inspiring awareness, acquiring understanding, and obtaining high participation rates in a broad audience who might, otherwise, not be motivated to care about climate change or carbon reduction, energy efficiency, and sustainability" (p. 4). We therefore hoped that relaying serious content and questioning assumptions through a game format might more easily reach a potentially less interested audience.

## Methods

As recommended by research on business tool development, the initial tool was developed based on knowledge from research and practice (Bocken et al., 2019). A tool prototype was developed in the form of a board game. The board game was developed to be played in-person to encourage group activities but there is also potential to create an online version of it. It is specifically meant to be combined with other tools and used as an introductory exercise to an ideation session or in-between sessions to review ambitions. It is designed to be used by businesses but should also prove useful for groups of students (particularly in business-related disciplines), for policy makers and academics. The low barrier, short duration character of the game (intended at around 30 minutes) should facilitate use in diverse settings. While a debrief after the game with a facilitator is intended, the game is self-guided and requires only a short instruction manual. The debrief would include discussing where the participants saw their own and their company's action before playing the game and then discussing where they think they should aim on the board. Some requirements that led the development process for the game are detailed in Table 1 with the resulting design decisions.

| The tool should | Design decision |
| --- | --- |
| … provide a vision of business sustainability that goes beyond the common strategies, to more sustainable actions. | The Hierarchy of SBM archetypes framework from Bocken & Short (2021) was adapted for the board to symbolize the 'ladder' structure of progress towards flourishing and the need to move beyond simple actions. |
| … be combinable with other tools. | The game is of short duration and broadly applicable, with a high-level vision and varied business examples to inspire across sectors. |
| … provide information on different levels of business sustainability and challenge existing assumptions. | Each level has an 'entry card'. The first player/team to cross into the level is asked to read the 'entry card' aloud, introducing the terms (e.g., circularity, sufficiency). Question cards contain multiple-choice questions related to the level, with a brief explanation for the correct answer. |
| … be based on sound information. | All questions and statements in the game are based on research and real-life cases. Every card has a disclaimer with sources so players can look up more information. |
| … inspire. | Cards include real-life business cases with sustainable business models and cases of bad business sustainability performance (e.g., greenwashing). Each real-life case is named and a source is provided. |
| … be fun. | The game is of short duration and involves a race character, so might increase competitiveness, but can also be played in teams and promote collaboration. 'Risk' cards are added to increase the unpredictability of the game, while providing information. There is a choice in the final level to take a shorter path with more 'Risk' fields, thereby offering variety. |

**Table 1. Design choices for The Road Ahead tool.**

Taking the Hierarchy of SBM archetypes as a starting point, several potential ways of designing the game were considered. Different prototypes were developed and reviewed with colleagues. The current (but not final) version of the game is presented in the results.

## Results

The Road Ahead is a board game for up to four players or groups of players. It is self-guided but should ideally include a debrief with a facilitator. Players take up the role of a fictional business and move across the board with six different levels, each representing an SBM archetype from efficiency to flourishing. Players start in the efficiency level and work towards flourishing. Each level (usually) has four steps and to move forward a step, the player or team must answer a question card from that level. Each level also holds one 'risk field' where a risk card is drawn. They hold brief descriptions of good or bad business sustainability performance (e.g., design for repair is good, greenwashing is bad) and the players move back- or forwards accordingly. Every card is read aloud, with another player posing the question and its multiple-choice options and then the correct answer and explanation after the answer attempt. Players can answer one question, then it is the next player's turn to keep up a fast pace and high engagement. If a question is answered correctly, the player moves forward. If the answer is incorrect, the player must stay on their position.

Each time a new level is entered, the first person to enter can turn over and read out lout the 'level entry card', a short introduction to the concept. Figures 1-4 show the game board, exemplary question cards, an exemplary risk card and a 'level entry card' for circularity.

## Discussion and Conclusion

In the next step, the tool will be reviewed by subject experts and tested with students, academics and, finally, companies to ensure that it fits company needs and expectations (Bocken et al., 2019). Since many serious games tools lack scientifically accurate assessments (Stanitsas et al., 2019), trial rounds will include data collection on the efficacy of the tool in achieving its learning objectives: understanding and encouraging more advanced sustainability actions. Participants will be asked about their knowledge of the different sustainability levels in advance and after the game. They furthermore will be asked about how ambitious they think their company is before and after the game. A survey will be developed to that end and short interviews might be integrated for more in-depth qualitative insights.

This research adds to existing work on serious games for business sustainability innovations. It provides a practical tool that complements and advances existing tools by challenging assumptions, setting a vision and demanding transformational action in a playful and engaging manner. We also gained research insights into the process of tool development that will facilitate future tool creation and might help improve existing tools. Future research into the impact of the tool will additionally provide knowledge into the ideal (revised) set-up of this tool and to what extent such a tool can promote learning for advanced sustainability actions in business model innovation.

# Nostalgia, gift, or nice to have – an analysis of unused products in Swedish households

**Karin Nilsson[a], Helena Strömberg[a], Oskar Rexfelt[a], Elin Ljungberg[a], Sandra Sköld[a]**
a) Chalmers University of Technology, Göteborg, Sweden

**Keywords**: Product attributes; Product Retention; Reuse: Design; Divestment.

**Abstract**: Ensuring the reuse of products once they have fulfilled their purpose at their first owner is one way of extending product lifetimes and a central part of circular economy. In Sweden unused products tend to be retained instead of recirculated, 72% of Swedes use half or less of what is stored in their households (Myrorna, 2018). This paper maps unused yet retained products to understand what causes retention, as well as explores barriers for reuse and the products' reuse potential. Responses from a diary study (n=45), capturing consumption and divestment behaviour were analysed using thematic analysis. Hassenzahl's (2003) concept of apparent product character was used as a framework to structure insights regarding unused products in households. Almost all participants retained multiple unused products. Analysis revealed three main types; products retained due to emotional value, products perceived as useful in the future, and products to dispose, consecutively mapping into SELF, ACT, and Unwanted character. Barriers to divestment for products of SELF and ACT character relate to their strong hedonic or pragmatic attributes as products embody memories, social relations, and identity, or a potential future utility. Divestment of these product types require detachment from the product. Products with weak hedonic and pragmatic attributes were also retained, but due to challenging disposition processes. This breadth of unused yet retained products indicates a complex relation between attachment, use, and disposition, where reuse potential varies. The discussion reveals that some product groups are suitable for recirculation outside of the household, while others hold potential for reactivation within the household instead.

## Introduction

Ensuring reuse of products once they have fulfilled their purpose at their first owner is one way of extending product lifetimes and central to circular economy. However, many unused products are retained in people's homes instead of recirculated (Gregson et al., 2007), and this amount is increasing (Maycroft, 2009). Sweden is no exception – according to a report from Myrorna (2018), a Swedish second-hand chain, 83% of Swedes had one or more unused products in their households and 72% had used half or less of what they keep in their storages within the last year. There seems to be an abundance of unused products stored in Swedish households, but why are they retained and what is their potential to be used again?

The decision to retain a product is described as one of the potential outcomes of a consumer's disposition process (Jacoby et al., 1977; Dommer and Winterich, 2021). For certain products retention is however not an intentional action, as unused products find their way into purgatories where they are kept in a liminal zone between use and disposition (Suarez et al., 2016). Poppelaars et al. (2020) call this phase of the consumption cycle 'divestment' and identify two subprocesses: disposition, the physical disposal of products, and detachment, the emotional and mental separation from the product. Thus, indicating the role product attachment, "the strength of the emotional bond a consumer experiences with a specific product" (Schifferstein et al., 2004, p.327), plays in product retention. While attachment can increase the longevity of a product (Mugge, 2005), it also risks increasing the retention of unused products (Dommer & Winterich, 2021) by making an already demanding product divestment process (Poppelaars et al., 2020) more challenging due to the relationship between person and product. Therefore, to understand which unused products are retained in Swedish household and why, this paper explores the relationship between persons and their unused yet retained products, as well as discusses the reuse potential of these products.

## Method

This paper uses data from a diary study conducted as part of a master's thesis (Ljungberg & Sköld, 2021). 45 participants completed a diary over four weeks capturing their retention and divestment behaviours and experiences. Participants were recruited through internet forums on several different topics. The 45 participants were spread across Sweden with most participants living in the southern part of Sweden, around its three largest cities. A majority (84%) of participants were women, aged between 22 and 68. There was an equal mix of single households, couples, and families with children.

**Figure 1. Diary pages with prompts of *five unused things* and *the black hole*.**

Diary studies allow participants to share and express details about their life and specific events through a guiding artifact; the diary (Hanington & Martin, 2012). The diary here (Figure 1) consisted of 10 pages with prompts for reflection (see more in Ljungberg & Sköld, 2021). The prompts focused on consumption and divestment patterns and frequency, and unused and unwanted yet retained products in the household.

For this paper, diary responses regarding unused or less frequently used products were analysed. Specifically, responses to two prompts were selected:

***"Five things you don't use, but still retain"*** where participants indicated five retained but unused products. The product descriptions and motivations of their retention in the responses provide a deeper understanding of which products are kept and why.

***"The black hole"*** where participants identified five products in their home that if they could, they would like to throw into a black hole to make them disappear without having to deal with them. In the motivations barriers to divestment can be identified.

The responses were coded and grouped into themes following a thematic analysis structure (Braun & Clarke, 2006) to find patterns in why the products had been retained within the home, resulting in eleven product groups. To deepen the analysis into the relationship between person and product, Hassenzahl's (2003) concept of 'apparent product character' was used. According to Hassenzahl, people construct the apparent product character based on the product's features and their own expectations; it describes their own personal experience of a product. It underlies emotions and behaviours connected to the product and the judgement of its appeal. The character consists of combinations of pragmatic, the product's perceived ability to help fulfil the user's behavioural goals, and hedonic attributes, emphasizing the individuals' psychological well-being, by providing "stimulation, communicating identity, and provoking valued memories" (p. 5). Further, peoples' perception of attributes can be either weak or strong and combining them creates four types of product characters: Unwanted, SELF, Desired, ACT (Figure 2).

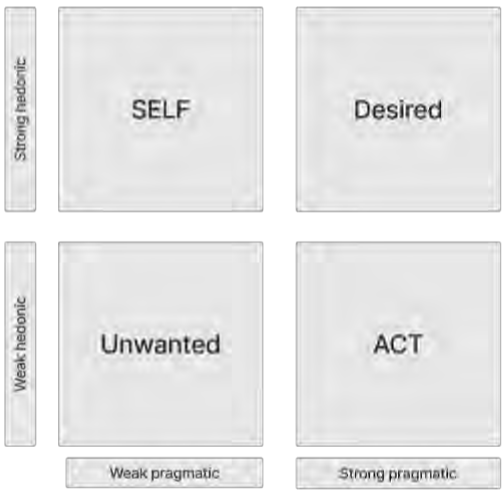

**Figure 2. Representation of apparent product character model, adapted from Hassenzahl (2003).**

The eleven product groups from the thematic analysis were mapped to their apparent product character type, based on the motivations in the responses, providing insight into how the owners perceive and value unused products in their households. This mapping was then used to discuss the products' reuse potential, as the owner's appraisal of the product is believed to impact retention.

## Results

The participants appear to retain unused products that fall within three of Hassenzahl's product character types, as seen in Figure 3. Most of the identified product groups map on a diagonal from being perceived as strong hedonic but weak pragmatic to strong pragmatic but weak hedonic, and thus fall within the SELF and ACT product character types. In relation to retention, the analysis shows that participants perceive some attributes that make the products valuable enough to retain, but they are also missing something to keep them in use. Two product groups fall in the Unwanted product character, revealing other reasons for retention of unused products. The product groups within each product character type are explained more in detail below.

### *Products within the ACT character type*

The retained but unused products interpreted in the analysis as having strong pragmatic and weak hedonic attributes in the participants' perception map under the ACT product

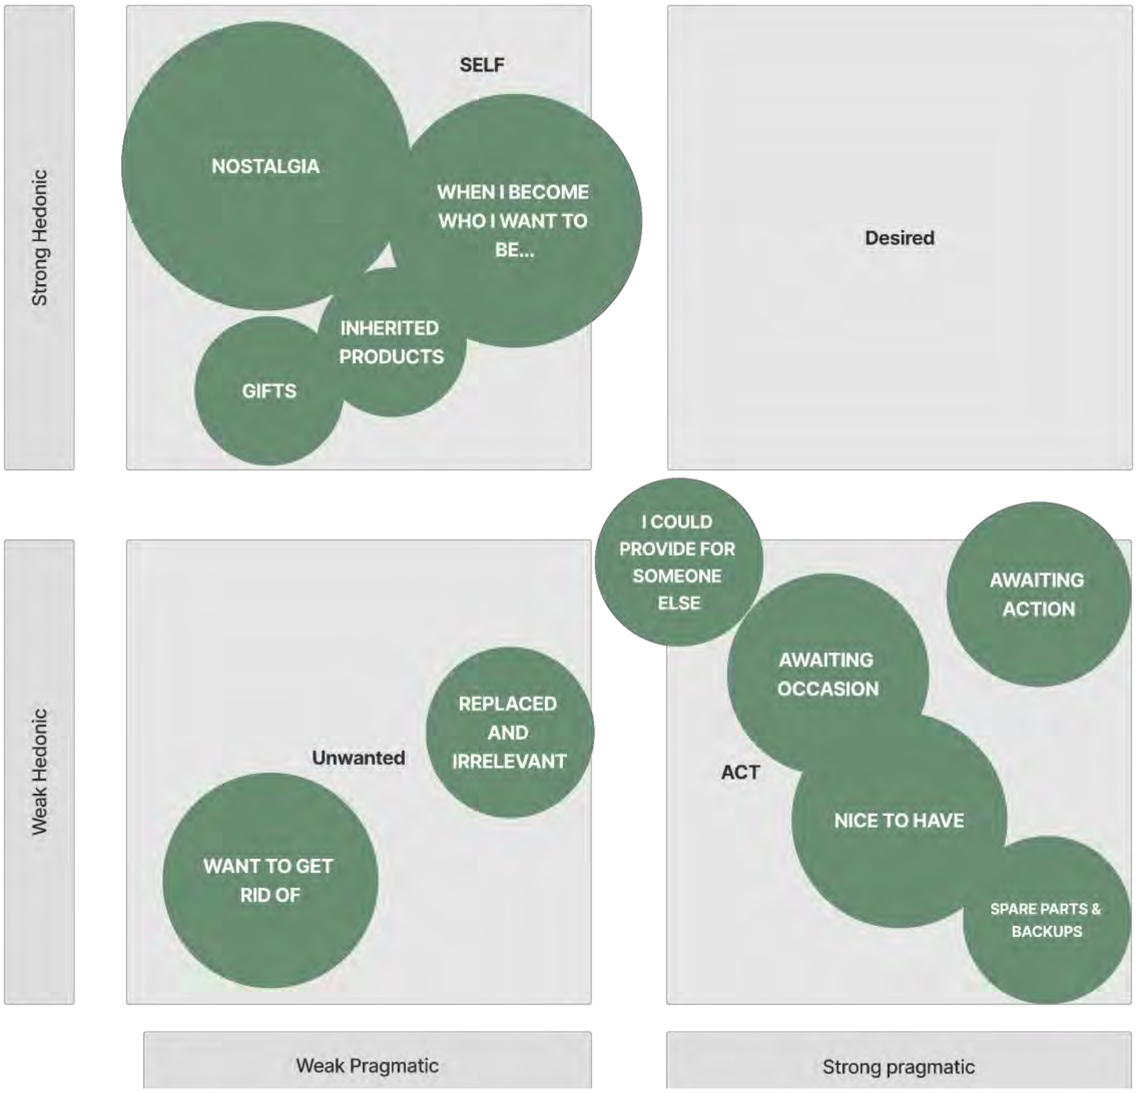

**Figure 3. Mapping of product groups in product character model.**

character type. These products are not in active use currently but hold a *potential future utility*. There are five product groups here.

Participants mention products that once supported behavioural goals in their lives, but currently do not match their situation, even if they could be useful again. Some are ***awaiting occasion*** when they will become used again, like *"Cast-iron candlesticks – the kids are too wild to have lit candles now. Will use in the future, love them!"*. The products in the group ***I could provide for someone else*** are instead retained to meet the needs of others, as exemplified by: *"Toaster. I don't eat bread anymore, but I might get a visitor who wants to toast"*. These products show a level of care and desire to be a good host, which is why they mapped with medium hedonic attributes as well.

Participants also mentioned products with a vague potential utility for their household. Many participants motivated keeping products due to their ***nice-to-have*** potential, foreseeing situations where the product could be useful: *"A saw. In case I need to saw something (has not happened yet)"*. However unlikely the future use, it still led to a hesitance to divest the product. Some participants tended to retain products for the purpose of having ***back-ups and spares***: *"old mobile phones, as soon as I get rid of them my new phone will break…"* or to ensure that resources were available for specific situations. More examples include left-over material like tiles and wallpaper that could be used to fix damages, or unused extra tools or appliances considered useful if the main one broke.

The final group in this character type are products ***awaiting action***. These products have a planned use in the household but require action, like a TV waiting to be hung on the wall. In contrast to the other four groups, these products were associated with concrete plans for use.

### *Products within the SELF character type*

Unused products interpreted in the analysis as having strong hedonic but weak pragmatic attributes map into the SELF product character type. In common for these products are that they carry value for their owner by representing memories, social connections, or ideas about the self.

The diaries showed that many unused products of a seemingly pragmatic character had been kept for a more hedonic reason. These products are kept for ***when I become who I want to be***, representing an ideal future life, different from their current. This category includes products the owner hopes to start using, like materials for hobbies and creative pursuits when they get time, or more mundane like the *"clothes iron – I live in the delusion that I will start using it more in my everyday life"*, as well as products they would like to use again like nice clothes of the wrong size. In keeping these products, the participants maintain the opportunity of living this life while also being aware that it will likely not happen.

Another strong driver for keeping unused products is ***nostalgia***. These products represent memories, and the participants often have strong attachments to these products, like *"Old tapes, nostalgia, so much effort and time went into recording them. Marks time"*. Typical products include toys, childhood memorabilia, and products representing life events, such as a wedding dress. ***Gifts*** and ***inherited products*** also come with strong attachments as they represent relationships of great value to the participants: *"coffee cups that were a graduation gift from my grandpa. Very pretty but too small to drink coffee out of"*. These products were typically kitchenware or furniture. They embody social connections with friends and family but remain unused as they rarely match the behavioural goals of their owner.

### *Products within the Unwanted character type*

Finally, the analysis revealed two products groups that map into the Unwanted character type; ***want to get rid of*** and ***replaced and irrelevant***. These were mostly products participants wanted to divest, but had not gotten around to, like *"clothes – waiting for the next flea market or the energy to sell them online"* or did not know how *"old electronics, difficult to sort, clean, and get rid of. Recycle vs. give to charity vs. sell?!"*. It also included products that had become irrelevant to the household as the behavioural goal they fulfil had been removed or fulfilled by a new product, rendering the product obsolete, but the divestment process had yet to begin – *"Kitchen Aid, when we moved in together, we suddenly had two. I really like it, but we really don't need one each?"*.

## Discussion

The analysis reveals a wide range of retained, unused products and a variety of reasons for their retention. Participants have kept both products they wish to keep and those they wish to get rid of, indicating a complex relationship between attachment, usage, and divestment. Furthermore, participants attach different meanings to the retention of certain products, suggesting that the reasons for keeping or divesting products are multifaceted.

The reuse potential of the identified product groups varies. For a product to be recirculated to a new household, it needs to be both divested from its current household and welcomed by a new one. However, some product groups, such as ***nostalgia*** and ***spare parts***, located at the endpoints of the SELF/ACT diagonal (Figure 4), have a low potential to be recirculated this way. The participants expressed a strong desire to hold onto these products, often viewing them as irreplaceable (cf. Schifferstein & Zwartkruis-Pelgrim, 2008; Kowalski & Yoon, 2022). For nostalgic products, the specific product specimen is valued as it is that specific instance which holds the memories of experiences or people (Mugge, 2017), while for the spare parts it would be difficult to find and replace the specific part when needed. Furthermore, it is unlikely that another household could experience the same values associated with these product groups.

However, while much literature on reuse (e.g., Poppelaars et al., 2020; Selvefors et al., 2019) focuses on reuse outside of the household, the diaries suggest another option: the products could be "reactivated" and reused within the same household (cf. Jacoby et al., 1977). Participants clearly see a potential future use or even a current value in many of their unused products.

For the other product groups, the potential for reuse in other households is believed to be higher (indicated by the pink area in Figure 4). Products with weaker pragmatic and hedonic attributes, such as ***gifts***, products ***awaiting occasion***, and ***nice to have*** products, are better suited for reuse outside the household because the owner's attachment to these products is not too strong, while the products could still be functionally and culturally relevant

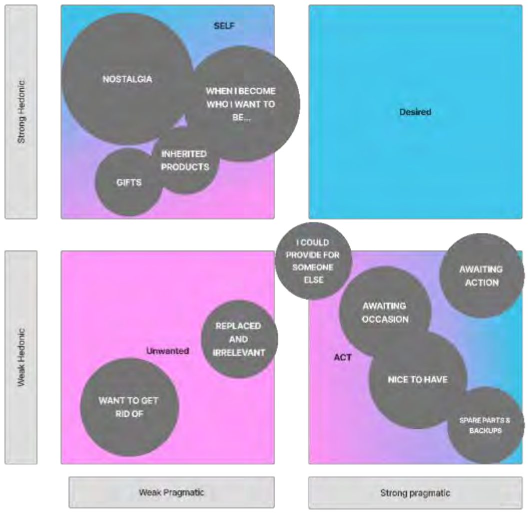

**Figure 4. Mapping of product character indicating the reuse potential within (blue) and outside of (pink) the household.**

to a new user. However, for these products, the divestment process is still challenging both in terms of detachment and the practical act of disposing of them. The Unwanted products from which the owner has already detached are even more suitable for reuse in other households because the practical disposition is the only remaining barrier.

Products with a stronger combination of hedonic and pragmatic attributes, such as products ***awaiting action*** and ***when I become who I want to be***, might be valuable for other households but still seem to hold the greatest reuse potential within their current households (thus positioned in the bluer area of figure 4). The owners' attachment to these products is high, and owners see specific scenarios of future use, indicating that the barriers for reuse within the households might be surmountable in many cases.

As previously mentioned, the relationship between attachment, usage, and divestment is complex. Our analysis reveals that many products are deemed meaningful to keep not only because of their potential to actively be used again but also because their mere presence in the household fulfills a certain need, prompting us to contemplate the concept of "unused". Furthermore, our findings demonstrate that attachment to products can be both beneficial and problematic, depending on where the product is most likely to be utilized, consistent with the results reported by Kowalski and Yoon (2022).

It must be emphasized that while the reuse potential of each product group is discussed on a general level, this does not indicate what each owner should do with a product from a certain group. For example, some of retained ***nice-to-have*** products will undoubtedly prove to be useful eventually, while others would be better off in someone else's household. Nevertheless, the general discussion about the reuse potential of products within the groups gives clues about the different challenges associated with them, which can be fruitful for anyone aiming to reduce the redundant product consumption that is manifested in the storages of people's homes. Current design efforts to keep products in use (e.g. Mugge, 2005, Chapman, 2009) are important in addressing this challenge. But, looking forward, we propose further research and design initiatives aimed at getting unutilized products out of people's storages and back into use – within or outside the household.

# A proposal for an exnovation process to 'design away' unsustainable practices in sustainability transitions

**Esther Noëth**[(a)], **Stine Moons**[(a)],
a) University of Antwerp, Antwerp, Belgium

**Keywords**: Sustainability transitions; Transition design; Exnovation; Design strategies; Systemic design.

**Abstract**: In the context of sustainability transitions, the literature has extensively covered the value of designers to envision desired futures and their ability to apply the necessary methodologies to innovate towards these futures. However, potential design strategies to take the other route and destabilize the reproduced and reinforced societal patterns of socio-technical regimes, remain largely unexplored. As transition theory states (Geels & Schot, 2007; Sharpe et al., 2016; Loorbach et al., 2017), both the scaling of niche initiatives and the dismantling of regime patterns are necessary in a transition process. The persistence of those existing patterns can slow down a sustainability transition substantially. By solely focussing on empowering and institutionalizing niche actors, the stature of regime actors, the ones that built and maintained the unsustainable practices, is kept in place. This research looks into the ways design strategies can be used to 'design the end'. Apart from defining the essential features of the old system that need to be maintained, as is already described in the three horizons framework (Sharpe et al., 2016), we looked into additional approaches to 'design away' the established practices. A proposal for an exnovation process consisting of different design strategies is presented, taking into account the characteristics of socio-technical transitions and the specificities of Horizon 1. Firstly, a literature review on transition theory and exnovation was executed, which resulted in a first draft of essential aspects of exnovation strategies. Secondly, a workshop with (transition) designers was organized to combine existing design practices and the concept of exnovation. In this workshop, the theoretical concepts of transition research were adapted to be applicable on an organizational level, thus readjusting the boundaries of the system from socio-technical level to organizational and ecosystem level. The exnovation process proposed in this paper exists of four main stages, i.e. (i) diagnosing the system and evaluating the status quo, (ii) visualising an empty future, (iii) designing the destabilization, (iv) designing (for) the end. For each stage, varying roles to guide different exnovation strategies are suggested. Lastly, the explorative framework resulting from the workshop was validated a first time with a transition design researcher. Further research should exist of additional validations and iterations of the framework and applying it in the context of an organization in transition to test its usability. As a final discussion, the critical question if designers actually have a central role in guiding exnovation processes and in depowering regimes is raised, asking for a more humble and nuanced approach of design strategies for exnovation.

## Introduction

In the domain of sustainability transitions, the body of knowledge dealing with the identification of desirable futures, viable business models, and necessary innovations for achieving sustainability goals is expanding rapidly. In contrast, little scholarly attention has been devoted to exploring the notion of breaking down unsustainable practices. From a transition perspective, understanding and applying this practice of breaking down is equally relevant. Transition research provides insights into the interesting dynamics between an upward innovation horizon towards desirable futures and a downward phasing-out horizon which is making space for a new future to emerge. This is captured in visualizations such as the X-curve (Hebinck et al., 2022) and the Three Horizons (Sharpe et al., 2016). The first steps towards defining phases in this breaking-down process are taken (Hebinck et al., 2022; Avelino, 2021), but actionable strategies are missing.

Although the conscious act of eliminating undesirable practices is slowly gaining more attention, the terminology used for describing this concept is still scattered throughout literature. Different descriptions can be found in several research domains apart from transition management, such as design, innovation and governance. The term 'exnovation' for example was first used by Kimberly in 1981, defining it as "that process whereby an organization decides to divest itself of an innovation that it had previously adopted" (Kimberly & Evanisko, 1981). More recently, the notion of exnovation was picked up in the design field, albeit using different terms like 'undesign' (Pierce, 2012) and 'designing away' or 'ways to kill a design in use' (Tonkinwise, 2013). These perspectives on exnovation focus on the role and the responsibility of the designer in breaking down previously established innovations on product, service and system level, but give little attention to the transition dynamics that are inherent to these practices of destabilization.

The literature on governance and exnovation gives us a better idea of this impact and how to manage these exnovations in sustainability transitions on a socio-technical level (Heyen et al., 2017; David, 2017; Graaf et al., 2021; Van Oers et al., 2021; Novalia et al., 2022; Onrust, 2021; Stegmaier et al., 2021). Here, the characteristics of sustainability transitions are translated to governance measures and policy mixes. This links directly to the economic perspective where concepts of 'degrowth' (Hickel, 2020) are gaining more momentum as an answer to current neoliberal, capitalistic narratives.

In the previous paragraphs it becomes clear that the building blocks for exnovation are available, but scattered throughout the literature and in different fields of research. In this paper, the argument for exnovation from a design point of view and on organizational or ecosystem level will be made. Design strategies, transition characteristics and organizational development practices will be combined in an explorative framework that makes exnovation on organization level actionable.

Based on the aforementioned literature, several key frameworks on exnovation were assembled and used in a workshop with design researchers and practitioners. The workshop led to an exnovation framework with four phases: (i) diagnosing the system and evaluating the status quo, (ii) visualizing an empty future, (iii) designing the destabilization and (iv) designing (for) the end. In each phase of exnovation, a collection of design strategies is proposed in order to enable a translation to actionable interventions related to systemic design principles.

The process of developing this framework was guided by three fundamental questions:

- Who should be doing this exnovation and who should have decision-making power in this process?
- Starting from an organizational perspective, on which level can and should we intervene to make exnovation possible and impactful?
- How can the actors of the system be prepared for the inevitable phase of chaos?

These questions will be discussed further in the results section of this paper. The following paragraphs report on the workshop that led to the first iteration of the explorative framework. In the results section, the framework is formulated in detail, zooming in on the different phases and their respective strategies, followed by a first validation of the framework with a transition expert. The paper concludes with several suggestions for further research by iterating on the framework and applying it in the context of an organization in transition.

## Methods

Due to the novelty of the exnovation concept and the underexposure of this dynamic in transition processes and management research, an explorative and iterative approach was chosen in selecting the appropriate research methods. A mix of (i) a literature review, (ii) a workshop with design experts and academic researchers in transitions, and (iii) a validation of the resulting framework by a transition design expert deemed as a good combination to address the research questions and come to a first understanding of what the design strategies for an exnovation process could consist of.

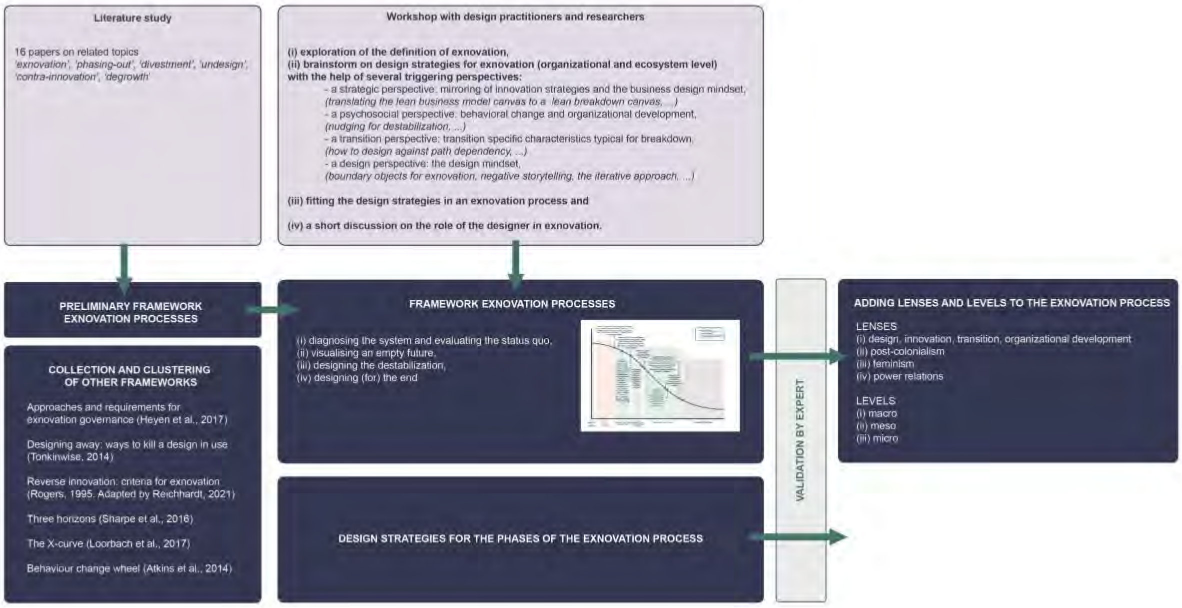

**Figure 1. Overview of applied research methods and outcome.**

First and foremost, a literature review was conducted to navigate the different definitions and perspectives that are emerging around the topic. As there is no consensus yet on the meaning of exnovation or its difference or similarity with other concepts such as 'phasing-out', 'divestment', 'undesign' and 'contra-innovation', they were all included in the review in an attempt to unify them in a common language. This resulted in a scoping of 16 papers. Definitions of what exnovation is or could be were filtered to come to one overarching definition that could serve as a basis to work with in the subsequent methods of this research project. After thorough analysis of the provided literature, a synthesis was executed existing of (i) a preliminary framework for exnovation processes and (ii) the collection and clustering of other frameworks relevant for the topic.

Subsequently, a workshop with both design practitioners and design researchers was prepared. Due to the short timeframe of this research project, the personal network of the researchers was activated in order to find participants. An invite was sent out to 13 people, of which 8 filled out the Doodle and 7 in the end attended the workshop. An overview of the participants and their relevant characteristics is given in Table 1.

| Participant nr. | Design expertise | Organization |
|---|---|---|
| 1 | research in systemic design and conflict driven design | university, department of product development |
| 2 | research in design for behaviour change and ecodesign | university, department of product development |
| 3 | research in systemic design and PSS design | university, department of product development |
| 4 | systemic design | systemic & human centered design agency |
| 5 | business model design, strategic design | strategic consultancy for sustainable businesses |
| 6 | research in sustainability transition design | university, department of product development |
| 7 | research in sustainability transition design | university, department of product development |

**Table 1. Overview of workshop participants and relevant characteristics.**

Because of the explorative character of this research, a diverse set of brainstorm techniques was involved. An overview of the detailed workshop is presented in Figure 1. The data of the workshop were captured by a combination of an audio recording, video recording and pictures of the written brainstorm outputs.

In a first attempt to validate the output of the workshop, the exnovation process and related design strategies were synthesized in a framework that was presented to a design researcher of a distinctive university, working on the topic of the role of design in transitions.

## Results

### *Defining exnovation*

To initiate the workshop and as a first warm-up exercise, participants were asked to shortly define what 'exnovation' means to them, if and how they have encountered it in their professional lives and what associations they make with the word. This led to several first insights, both complementary and contradictory to the definitions found in the literature.

*should undesign them."* (refering to Perera & Fry, 2022)

*"To break certain current strategies or interventions down instead of building them up, because they are not how we want to go forward."*

In order to establish a common language for the continuation of the workshop, the researchers proposed an overarching definition of the concept. Exnovation was defined as: "*a set of interconnected design strategies to phase out or design away unsustainable practices on an organizational level and ecosystem level. This can involve intervening in the content, the strategy, the governance or management, but also the company culture".*

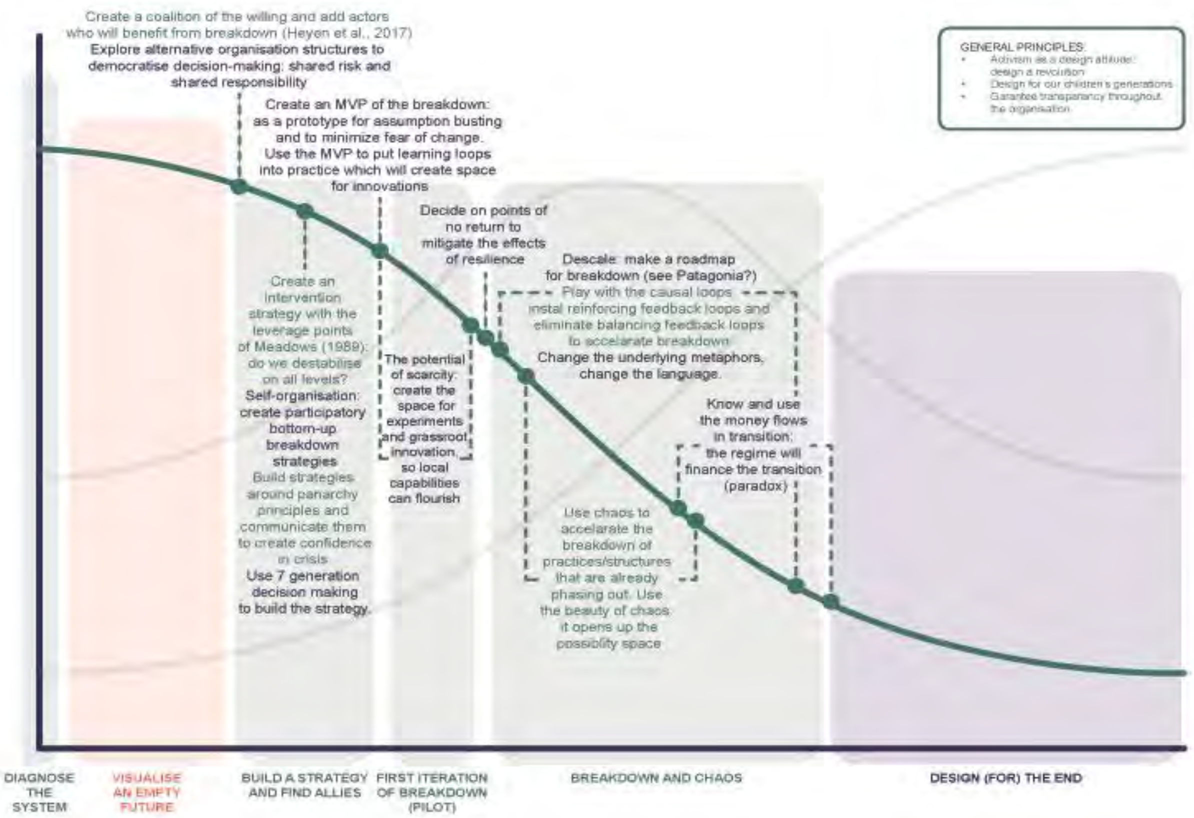

**Figure 2. Overview of the exnovation framework.**

*"Like Tony Fry said: the future is already filled with plenty of design things of the past, and we*

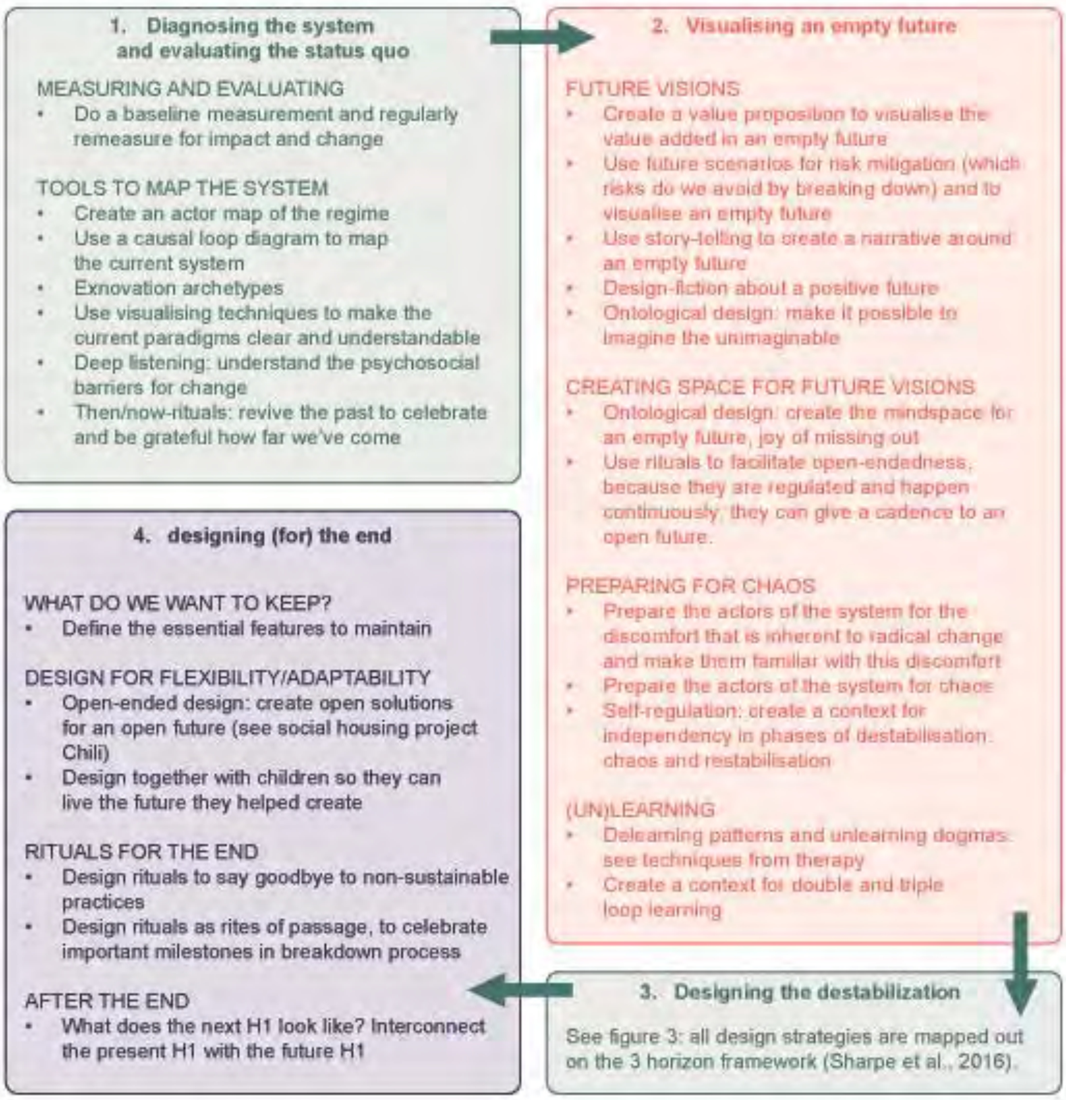

**Figure 3. Overview of design strategies for exnovation.**

*Building the framework*
As a second exercise, a brainstorm on design strategies for exnovation on both organizational and ecosystem level was executed.

The participants were asked to frame ‘design strategies’ as open as possible for themselves, thus including tools, methods, frameworks, practices and skills. Building on this output, an attempt to restructure these design strategies into the phases of the exnovation framework was made. As this framework (Figure 2) is based on transition frameworks such as the X-curve (Hebinck et al., 2022) and Three Horizons (Sharpe et al., 2016), the exercise started from the perspective that different design strategies are relevant and needed during the various ‘phases’ of the transition process.

*Detailed overview of the framework*
An overview of the structured design strategies can be found in Figure 3. The first phase is an evaluation phase: the system is mapped out and ‘diagnosed’ as it is. Deep listening techniques, actor mapping and causal loop diagrams (Jones & Van Ael, 2022) can be used to get an idea of the structures and patterns that need to be broken down. During the workshop,

the concept of 'exnovation archetypes' was discussed.

This concept could be developed in more detail when there is more evidence from exnovation cases available, making it possible to see 'break-down patterns' that will help organizations to foresee what is to come. After mapping, a first bridge is made towards the last phase (4. designing (for) the end), by deciding which essential features of the system need to be maintained, but also by designing rituals that revive the past, to celebrate and be grateful about how far the organization has come.

Lastly, some efforts need to go to measuring certain system indicators and evaluating them, making it possible to compare this baseline measurement with later monitoring efforts in order to estimate the impact of breakdown practices.

The first phase (1. diagnosing the system and evaluating the status quo) is followed by a phase 2.) visualizing an empty future. In this phase, the attention needs to go to visioning techniques and creating the (mental) space for organization members to interact with those future visions and the following destabilization phase. By creating these images of what a future could be without de established structures of the organization and the space it could create to be filled in by innovations and novel practices, the exnovation becomes worth working for. Techniques and strategies that can be used are future scenario thinking, story-telling, design-fiction and a 'reverse' value proposition (which value do we create by breaking down certain practices and structures?). As mentioned above, creating the context to interact with the concept of an empty future is essential for a meaningful exnovation. To create this context, delearning techniques from decolonization practices, education studies and organizational management (Azoulay, 2019; Kimmerer, 2015; Korteweg & Fiddler, 2018; Cegarra-Navarro & Wensley, 2019) can be used, complemented with strategies to create double and triple loop learning (Senge, 1990) in the organization. In this phase, the actors in the organization also need to prepare for the unavoidable chaos phase in the breakdown. Methods and exercises to become familiar with this chaos and the corresponding discomfort, and to create a degree of self-regulation and independence of actors and actor groups, can be useful.

In phase 3.) designing the destabilization, the actual breakdown of existing structures and practices happens. This phase can be subdivided in 3 parts: (i) building a strategy and finding allies, (ii) first iteration of breakdown or pilot, and (iii) breakdown and chaos. In part (i), the coalition of the willing for breakdown is built. Heyen et al. (2017) provide more detail about this coalition and the necessary preconditions it entails in their classification of exnovation techniques on governance level: this coalition is preferably a diverse group of actors from both the organization and its ecosystem, and can be supplemented by actors with goals and motives beyond the transition of the organization (Heyen et al., 2017). Apart from building a coalition, questions of decision-making and shared responsibility need to be answered in this part, possibly entailing a change in the organizational structure. With this coalition, a strategy for breakdown can be developed. Possible tools can be Meadows' intervention strategy (1997), the panarchy principles (Holling, 2001), seventh generation decision-making (inspired by acient Haudenosaunee philosophy) or self-organization tools to create participatory bottom-up breakdown strategies. In part (ii), a pilot version of the breakdown can be put in motion. This pilot could help to mitigate fear of change, bust assumptions and create a first learning loop. By working with a pilot of breakdown, the potential of scarcity can be explored, creating the space for experiments and grassroot innovation. After a successful pilot, a last step needs to be taken before diving into the actual breakdown: the organizations' decision-makers need to define certain milestones or 'points of no return' in the time to come. When these points in time are passed, going back to the system as it was is no longer an option. These points of no return are essential to mitigate the effect of the systems' inherent resilience and its tendency to stabilize into the status quo. In part (iii), the breakdown starts. The degree of control goes down in this part, and apart from a dynamic roadmap, the best strategies involve 'dancing with the system': the destabilization can be accelerated by creating new reinforcing feedback loops or taking away balancing feedback loops, chaos can be used to open up the possibility space. In this part, the moment has come to start changing the language of the organization and its underlying metaphors (Inayatullah, 2017). To conclude phase 3, it is important for the exnovation coalition to understand and use the money flows in transition: during and after the chaos, the resources that financed the established structures, will be relocated to finance the scaling of innovations. Timing this right will boost innovations and truly transform an organization.

After the tumultuous phase 3, the exnovation process comes to a conclusion in phase 4.) designing (for) the end. Strategies that are developed in the previous phase, need to be brought to a close with an open end, creating space for flexibility and adaptability of the organization in transition. It could also be interesting to start looking for a connection between the newly established structures after breakdown and a new horizon 1. Finally, this phase holds a great opportunity for designing rituals that help the actors in an organization to say goodbye to non-sustainable practices and to celebrate important milestones in the breakdown process. Providing space to mourn what is broken down can be a meaningful practice that provides peace of mind for all involved and affected actors.

### *The role of the designer*

A last part of the workshop focussed on the role of designers in exnovation interventions. It quickly became clear that the complexity of these kinds of interventions, certainly on an ecosystem level, require the involvement of several practitioners with different expertises in the form of a transdisciplinary team.

*"The team must have a mix of power, legitimacy, knowledge, dynamism, interest and urgency."*

The designer can participate in this team in different ways. Possible roles were debated on, such as the devil's advocate, the process facilitator or the sensemaker who makes a complex process tangible and actionable.

*"(…) In terms of transitions, you design a context in which you enable people to design stuff, but whatever they design is restricted by (the) constraints you've put in your (…) facilitating process. (…) You are very much the catalyst of designing the outcome."*

The workshop ended with the consensus that designers can have a role in an exnovation process, but they need to be careful to not overestimate that role and that transdisciplinarity is essential to be able to tackle the complexity of transition in an impactful way.

### *Validation*

As a first validation, the output of the workshop was presented to a transition design researcher. She framed the exnovation framework as very promising, capturing the potential for multiple research projects zooming in on the different phases and the design strategies within. Several guiding questions for further discussion were formulated:

- How do we balance the linearity of the visualization with the need for a dynamic, iterative, cyclical process? How are these phases intertwined in a transition process?
- How is the exnovation process nested in the bigger picture of transition? How does it interact with the dynamics of Horizon I and III (Sharpe et al., 2016)?
- Here the lenses of design, innovation management, transition and organizational development were used. What other perspectives might enrich the exnovation process?

After the discussion, a collective proposal was formulated to elaborate further on this concept of exnovation and look into the possibility of framing it in a matrix to tackle multiple levels (macro, meso, micro) and different phases. The matrix could outline the playing field for different lenses to be applied, e.g. a feminist, post-colonial, governance or power lens.

Lastly, the opportunity to gather an interdisciplinary community of researchers around this emerging research field adding unique lenses from different research disciplines, was formulated.

## Discussion & conclusion

The concept of exnovation is still new in transition design research. A first, explorative framework is presented in this research, making the process more actionable from a design point of view. The framework consists of four phases: (i) diagnosing the system and evaluating the status quo, (ii) visualizing an empty future, (iii) designing the destabilization and (iv) designing (for) the end. In each phase, multiple design strategies, methods and tools are provided to facilitate the process of breaking down the established, unsustainable structures and practices in an organization and its ecosystem. To reap the benefits of this framework, it needs to be validated by empirical research in multiple environments, iterating on the phases and their respective design strategies. Additionally, every defined design strategy, method and tool opens up a new research space to gain more insights into their further detailing, applicability and effectiveness in the exnovation process. Furthermore, the question of who will facilitate this process is still unanswered: suggestions were made during the workshop, but additional research on the specificities of a transdisciplinary team and their relation to the system in transition needs to be elaborated further.

Lastly, it should be emphasized that, although exnovation in itself constitutes an exciting new field of research, it is always nested in a bigger transition process, thus existing in relation to both horizon I and horizon 3. Connecting new research on exnovation (horizon 1) and existing research on the role of innovation in sustainability transitions (horizon 3) might lead to new insights on this topic: both exnovation and innovation interventions are an entangled part of a dynamic intervention model to bridge multiple transition horizon perspectives and steer systems towards more regenerative futures.

# Circular business models and supporting policies for reusing of photovoltaic modules in the EU

**Nyffenegger, R.**[a,c], **Baldassarre, B.**[b], **Bocken, N.**[c]
a) Bern University of Applied Science, Bern, Switzerland
b) Joint Research Centre of the European Commission, Sevilla, Spain
c) Maastricht Sustainability Institute, Maastricht, The Netherlands

**Keywords**: Reuse, solar industry, photovoltaics, circular business model, regulatory framework, value chain resilience.

**Abstract**:
Renewable solar energy is essential to achieve the Paris climate agreement. The EU faces two main challenges. First, the increased photovoltaic (PV) capacity installed today will result in enormous amounts of waste at the end-of-life of PV modules. Second, the EU is currently dependent on the imports of PV modules, manufactured outside the EU using fossil fuel sources and critical raw materials. Circular strategies (i.e., reduce, reuse, recycle) may help address these challenges. Here, we focus on reuse, which according to the EU waste framework directive should be prioritized over recycling. Based on a review of academic and industry literature and exploratory interviews with industry stakeholders and policymakers, we shed light on the reuse business models of PV modules, and the EU policy context. Four main reuse business model archetypes were determined: (1) opportunity-driven diversifier; (2) socially-driven orchestrator, (3) turnover-oriented trader, and (4) state-appointed collector. All reuse business models are shaped by the EU policy landscape. This landscape includes the upcoming Ecodesign requirements for new PV modules placed on the market; the directive on Waste from Electrical and Electronic Equipment (WEEE) determining end-of-life requirements; and in between a regulatory gap related to enforcing potential reuse activities. The identified circular business model archetypes and EU policies are finally discussed to inform potential future research, business, and policy actions to make the European PV industry more circular and resilient.

## Introduction

The deployment of renewable energy sources has been growing significantly in recent years (IRENA, 2022). As one of the most important renewable technologies, solar photovoltaic (PV) power is experiencing a remarkable acceleration reaching 209 gigawatts (GW) of installed capacity by 2022 in Europe (SolarPower Europe, 2022). At this rate, the predicted 891 GW by 2050 may be overtaken (IRENA, 2019; SolarPower Europe, 2022).

This boost in PV deployment entails two key challenges. The first challenge relates to finding adequate solutions for the waste generated by end-of-life PV modules. Projections estimate up to 33 million tons of end-of-life PV modules by 2050 in Europe alone (Czajkowski et al., 2022). Second, the demand for PV creates import dependencies for raw materials as well as PV modules and therefore supply vulnerabilities (Carrara et al., 2020; European Commission, 2022a).

To address both challenges, circular economy (CE) strategies become a key driver. Reduce, reuse, and recycle (3R) are most relevant in the PV industry (Komoto & Lee, 2018; Rabaia et al., 2022). Reduce includes all activities related to material savings through increased resource efficiency, or avoidance of (especially hazardous) materials (Weckend et al., 2016). Reduction activities are either economically motivated (Fraunhofer ISE, 2023) or regulatory motivated, if e.g. hazardous substances have to be disclosed (European Commission, 2020; European Environment Agency, 2021). Reuse includes all activities related to the preparation for reuse as second-hand modules, including PV module collection, transport, storage, cleaning, quality testing as well as simple repair operations like bypass diode(s) or cable connector replacements (Tsanakas et al., 2020; van der Heide et al., 2022). Reuse activities are so far practiced only in niche areas and are not yet considered profitable on a large scale, but are expected to increase significantly in the future (Deutsche Umwelthilfe, 2021; van der

Heide et al., 2022). Finally, recycling includes all activities related to disassembly and delamination of PV modules, as well as material sorting and extraction (Deng et al., 2022). Since the majority of PV module recycling practiced today is downcycling, the recycling of PV modules is still in its infancy, with both technical and non-technical hurdles (Czajkowski et al., 2022; Salim et al., 2019). The legal frame for recycling is provided by the Waste from Electrical and Electronic Equipment (WEEE) directive, which sets targets for collection, recovery, and recycling of PV modules (Chowdhury et al., 2020).

Research on PV end-of-life management is predominantly focused on recycling despite this being the least preferred option in the waste hierarchy (Komoto et al., 2022; Salim et al., 2019). In contrast, little research focuses on PV reuse because of insufficient economic incentives and an unknown legal design framework (Komoto & Lee, 2018; van der Heide et al., 2022). However, estimates suggest that up to 50% of the PV waste modules are suitable for reuse. Thereof, a considerable part are PV modules that have defects upon production or transportation, which therefore have never been installed, and PV modules with infantile failures over the first four operational years (Tsanakas et al., 2020). A substantial amount of those PV modules suitable for reuse is, however, expected to be bypassed by the collection systems as the total amount of collected PV modules in the European Union reported to WEEE is still low compared to the expected amounts (Deutsche Umwelthilfe, 2021; van der Heide et al., 2022). This significantly reduces the volumes for reuse and recycling as PV modules are exported to non-European countries as first reports on emerging illegal trade and disposal of PV modules indicate (INTERPOL, 2020).

This paper aims to contribute to the PV module reuse research stream by mapping current reuse business models against the relevant policy context. Since the preferred end-of-life management of PV modules is closely interlinked with regulatory interventions a holistic approach analysing the current state of reuse activities from a business model and policy perspective is chosen. Specifically, we show which business models prevail and which policies are in place or planned that affect reuse activities.

## Method

To map current reuse business models against a policy context and analyse the current state of PV module reuse we applied an exploratory research design. Exploratory research consists of a broad-ranging, purposive, and systematic attempt to discover something new, and leads to an understanding or description of an area (Stebbins, 2001). We chose a multi-method research design to explore immature concepts that need to be described (Creswell, 2014; Morse, 1991). We first conducted desk research, followed by expert interviews.

For the desk research we analysed the emerging research landscape around CE in the PV industry, especially concerning the end-of-life management of PV modules. Besides the academic literature also non-academic literature such as company documents, industry reports, policy documents or

whitepapers were considered. For the expert interviews we conducted semi-structured interviews with PV experts and stakeholders from industry and policymaking. A total of 12 expert interviews lasting about 1 hour on average were conducted in 2022 and 2023. Table 1 shows an overview of the interviewees. The collected data was analysed by first familiarizing with the recordings and interview notes, followed by coding the data into initial segments, searching for broader themes, reviewing those themes, and naming those themes (Braun & Clarke, 2021). The steps were conducted individually by the authors and discussed periodically.

## Results

### *Reuse business models in Europe*

Business models offering reuse, repair and refurbishment activities in the PV industry are gaining momentum. Although these business models, which are mainly carried out by organizations that have no connection to the original manufacturers, are currently seen as rather informal (European Commission, 2020), first business model types are emerging. Our results distinguish four reuse business model archetypes, which are shown in Figure 1.

<u>Opportunity-driven diversifier</u>

Opportunity-driven diversifiers generate value by providing PV system owners an alternative to recycling, which is in line with CE principles of slowing the loop and – more importantly – reduces disposal cost (interviewee 3). This alternative is reuse: by feeding back some of the decommissioned PV modules into reuse, the opportunity-driven diversifier reduces recycling fees for the system owner and opens a new business opportunity for him/herself (interviewees 7, 12).

<u>Socially driven orchestrator</u>

The value proposition of the socially driven orchestrator is to allocate written-off PV modules from commercial companies to social projects through the orchestration of a vast network of partners. On the one hand, this allows commercial companies to present themselves as socially and ecologically responsible without making a financial commitment (interviewee 9). And on the other hand, social projects profit from fully tested, circular reuse PV modules at a reduced price compared to new modules (interviewee 9).

<u>Turnover-oriented trader</u>

The turnover-oriented trader offers PV system owners hassle-free disposal of their PV modules at the end of their service life, while also avoiding the recycling fee. The value proposition is largely profit-oriented without positive impact on people and planet (interviewees 3, 7). Value is created by shipping the PV modules to non-European countries, often without testing all PV modules or testing at all (interviewees 7, 8, 9, 11).

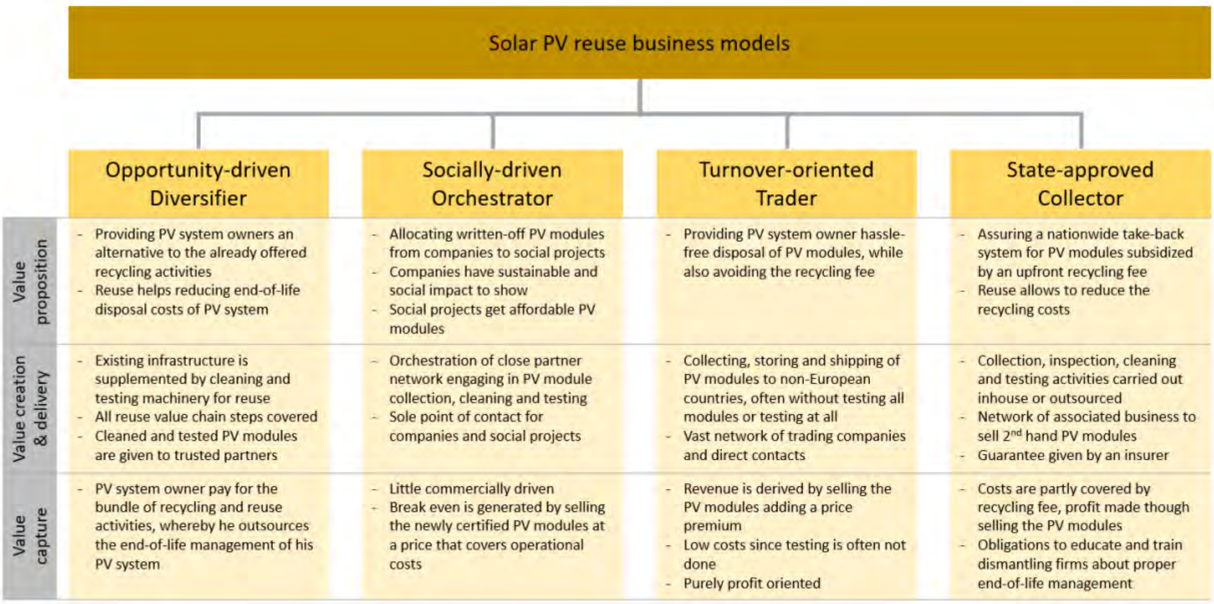

**Figure 1. PV reuse business models.**

State-appointed collector

The value proposition of the state-appointed collector is rather directed at the state then other stakeholders, as he ensures a nationwide take-back system for PV modules, which is subsidized by an upfront recycling fee (interviewee 6). Out of the PV modules coming into the collection streams a certain amount is foreseen for reuse (interviewees 3, 6).

Overall, reuse business models for PV modules are accelerating across Europe. Different business model archetypes emerge, which are often also shaped by the respective regulatory environment. As waste streams increase, reuse business models will continue to evolve and adapt.

### *Policy context for reuse in Europe*

The emergence of CE business models for PV reuse is influenced by the policy and regulatory context. For PV reuse the regulatory context primarily includes upcoming Ecodesign requirements for new PV modules placed on the market and the WEEE directive determining end-of-life requirements. The interviews allowed to crystallize the understanding of policy and regulatory context.

Ecodesign regulation

When new PV modules are placed on the market, the EU envisages new regulations under the name of Ecodesign, which are now being developed (interviewees 8, 11, 12). According to a preparatory study (European Commission, 2020) and a discussion paper (European Commission, 2021), the Ecodesign regulation for PV modules aims: (1) to foster long-term energy yield based on information requirements and a quantitative threshold; (2) to introduce stringent quality and durability tests to withstand prolonged exposure in open-air climate; (3) to set the basis for a unified long-term performance degradation calculation by setting definitions, calculation boundaries and disclosure requirements; (4) to ensure potential repairability of PV modules through a reporting requirement of how to access and replace bypass diodes or the whole junction box; (5) to enable higher recyclability by setting reporting requirements on the dismantlability of certain product components and the material disclosure of selected raw materials: (6) to establish a standardized basis of the ecological profile of PV modules based on a life cycle assessment approach focusing mainly on the global warming potential, also referred to as the carbon footprint. Going forward towards legally binding actions for PV modules, emphasis is expected to be placed on: (1) resource efficiency requirements; (2) carbon footprint requirements; (3) and information requirements (interviewees 9, 10, 11).

Directive on Waste from Electrical and Electronic Equipment

The WEEE directive introduced by the European Commission in 2012 comes into play at the time the PV modules are withdrawn from the market (interviewees 1, 11). The purpose of the WEEE directive is to contribute to sustainable production and consumption through avoidance, reuse, recycling, or other forms of recovery of such waste (European Union, 2012). PV modules fall under the category four and therefore have a minimum target of 85% recovery rate, whereof 80% shall be reused and recycled (European Union, 2012). Even though PV modules are covered

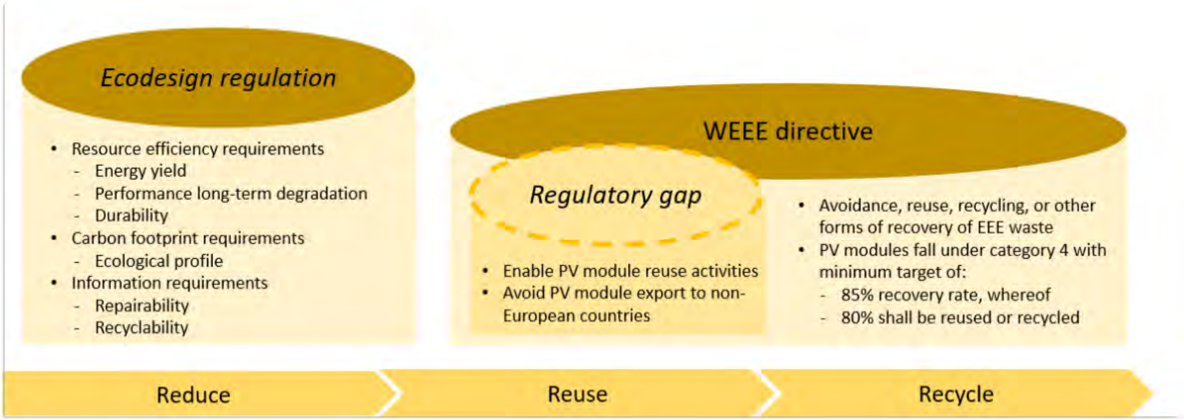

**Figure 2. Policy context of CE activities (reduce, reuse, recycle).**

by the WEEE directive, the regulation is not directly and specifically focused on PV modules (interviewees 4, 8). Only by 2019 PV modules are foreseen to be reported as a separate category as laid down in an implementing decision (European Union, 2019).

Regulatory gap related to enforcing potential reuse activities

Figure 2 shows the different policies elaborated in the context of CE activities (reduce, reuse, recycle).

Neither the upcoming Ecodesign regulation nor the WEEE directive address the enforcement of reuse activities directly (interviewees 8, 10, 12). The resource efficiency requirements within the Ecodesign regulation might foster the durability of PV modules and therefore more potential usage cycles. Additionally, the information requirements on repairability of PV modules might foster reuse activities (interviewees 2, 8, 10). However, the information requirements are not linked with specific mandatory reuse actions and PV modules are seen as difficult to repair comprehensively in practice (interviewees 5, 7). The WEEE directive on the other side, includes reuse as an option to deal with electrical and electronic equipment (EEE), but foresees no distinguishment between the final end-of-life strategy, meaning between reuse and recycling (European Union, 2012). As a result, adequate data on reuse activities are not yet available, which makes a quantification of reuse activities in Europe nearly impossible (interviewees 3, 5). Since reuse is not statistically reported, nor mandated by the WEEE Directive and generally not considered financially viable, most PV modules are steered towards recycling (interviewees 3, 6, 8, 11).

It can therefore be stated that there is, to date, no mandatory legislation to enforce reuse of PV modules (interviewees 8, 9, 11). As a result, PV modules in today's PV industry still circulate very little as second-hand modules as envisaged in the CE (interviewees 2, 6, 10). This comes in combination with different challenges: (1) PV module reuse business models are currently still niche and therefore policy awareness is low; (2) outflow of PV modules is high due to extensive trade with non-European countries; and (3) reuse and recycling players compete for volume to make their business models profitable (interviewees 4, 5, 7, 8, 9). From a CE perspective this is problematic, as no regulatory incentives are given to reuse activities, which generally are prioritized over recycling according to the EU waste framework directive. From the point of view of businesses operating in the field of reuse, there are uncertainties regarding the legal spheres of operation of their business models.

Overall, the regulatory context for PV module reuse business models is tenuous and current policies might not allow scaling up on the industry side. To promote activities that are considered preferable to recycling from a CE perspective, appropriate regulatory frameworks might be needed going forward (Figure 2).

## Discussion and Conclusion

The aim of this paper is to investigate circular economy models based on reuse in the PV industry against the background of EU policy. Despite the drain of a significant amount of PV modules suitable for reuse to non-European countries, reuse business models in Europe are gaining some momentum. Four main reuse business models have been identified, namely the opportunity-driven diversifier, the socially-driven orchestrator, the turnover-oriented trader, and the state-approved collector.

All four business model archetypes are expected to accelerate as PV module waste grows considerably in the upcoming years. However, the relevance of the CE regulatory context, current and foreseen legislative measures might not yet directly support the emergence of reuse business models. Neither the upcoming Ecodesign regulation, which sets rules for placing new PV modules on the market, nor the existing WEEE directive, which determines end-of-life requirements for EEE, contain mandatory measures to catalyse the emergence and scaling of PV reuse business models, to date.

This regulatory gap could be problematic for three reasons. First, it might lead to an indirect prioritization of recycling over reuse through the WEEE directive, which is conceptually in contrast with the EU waste hierarchy framework. Second, the inherent circularity potential might not be fully realized, which could have a negative impact on strategic dependencies. Relatedly, the export of PV modules to non-European countries leads to the export of valuable materials (e.g., aluminium) that are then not available as input factors, again aggravating import dependencies, but also shifts the waste problem to countries that do not have the infrastructure to adequately deal with this waste. The understanding of the identified reuse business model archetypes is therefore of upmost importance to develop reasonable regulatory interventions, which support those business models that are in line with the overall CE aims of the EU. Figure 3 shows the elaborated relationships and dependencies.

This paper has implications for different stakeholders. Business practitioners will learn four business model patterns for value generation in reuse and best practices to better assess their own stage of development. Policy makers can gain insight into the effective activities and challenges in the reuse business that can be included when considering new regulations or adapting existing ones. To research in the renewable energy field, the paper contributes by analysing emergent circular business models simultaneously against their policy background, by using PV as a case study.

This paper comes with limitations, mainly regarding to its exploratory approach and restricted scope. Further research is needed to examine the business models and corresponding policy context of reuse activities around PV modules in Europe. First, the estimated material flows indicated in Figure 3 should be quantified to get a better understanding of the underlying business models and accurate policy measurements. Second, further research should focus on impeding aspects that complicate the activities of reuse business models, namely issues of product safety, the lapse of warranties, the question of future liabilities, the influence of feed-in tariff agreements, and the importance of the cost of balance-of-systems components. In doing so, research should, thirdly, assess reuse business models from a more holistic perspective, assessing the reuse potential of PV modules also from a demand perspective.

# Understanding long lasting design through tangible tokens

**Ayşegül Özçelik[a], Markus Löchtefeld[a] & Christian Tollestrup, [a]**
a) Aalborg University, Aalborg, Denmark

**Keywords**: Design for longevity; Research methods; Tangible tools.

**Abstract**: This paper presents the development of new interview tools to conduct interviews by incorporating physical tokens embedded with concepts related to product longevity. The objective is to augment the depth and quality of qualitative interview data in the field of longevity and sustainability studies.

## Subtitle/ Introduction

Longevity is one of the prevalent concepts among many in the design for sustainability literature (Ceschin & Gaziulusoy, 2016). It claims that keeping the product in use may decrease the need for new production, thereby decreasing the environmental impact. The concept of circular economy (Ellen MacArthur Foundation, 2013) argues to protect the product's value until its end of life and create several loops before the product goes out of the cycle. When aiming for longevity, we focus on the product's use, maintenance, repair, exchange, recycling and disposal phases and related concepts.

When products involve integrated digital technologies, the longevity of the product becomes a more complicated issue. Discussing longevity and going beyond the surface level, particularly when gathering data regarding lifetime and sustainability of products, can be difficult when working with industry informants due to their wish for a positive perception of their products. Furthermore, while some of the academic longevity concepts are widely used in the industry with increasing interest in long-lasting and sustainable products, the terminology might differ.

In our work, we focus particularly on connected products (Raff et al., 2020), which are known for having a high use and disposal rate. We conducted semi-structured interviews with design practitioners from industry to understand how they approach longevity in their work. To support these semi-structured interviews, we designed a simple toolkit including tangible tokens that served as prompts and triggers for discussion with participants. The design of the toolkit began with a grounding in previous literature review studies. We developed a set of physical tokens with shapes according to key themes and inscriptions from key concepts in the sustainable ICT and design for sustainability literature.

We present the reflections of interviews with 12 participants and highlight the advantages and disadvantages of utilizing tangible tokens during semi-structured interviews.

### *Tangible tools*

Donald Schon gives a familiar example from daily life to exemplify the knowing-in-action: *“a touch-typist, who cannot say offhand just where all the letters are located on the keyboard, can begin to type, even on an imaginary keyboard, and thereby find the "T" just underneath the second finger of the left hand, the "L" just underneath the fourth finger of the right hand, and so on”* (Schon, 1983, pp54) He proposes that design knowledge can be exposed in doing (Schon, 1983). In line with this perspective, tangible tools initiate actions; therefore, participants may reflect on meanings, assumptions, and new solutions, which can enrich qualitative data during interviews (Buur, 2018). Supporting conversations with such tangible tools can help researchers gain deeper insights into the implicit level (Sanders & Strappers, 2012) of understanding of the interviewee.

In participatory design, one of the key aspects is that the researcher takes on the role of a facilitator, assisting the participant in articulating and expressing their experiences while minimizing bias as much as possible. There are three main approaches to elicit information and obtain creative data in participatory design practices such as probes, generative toolkits and prototypes. While probes (Sanders & Strappers, 2014) are used to elicit a response, they help participants reflect on their ideas, feelings, and experiences. Similarly, generative toolkits are commonly utilized in facilitated collaborative activities and can be used to make artifacts to explore the problem or imagine the future (Sanders & Strappers, 2014). Furthermore, the resulting products and descriptions can be examined to get an understanding and empathize with the user (Sanders & Strappers, 2014). Prototypes are used to represent ideas and concepts to receive feedback about the emerging design (Sanders & Strappers, 2014). In this paper, we follow up on these ideas and extend them to gather data in qualitative semi-structured interviews. For this, we introduce a toolkit developed based on longevity concepts derived from a literature review study.

## Methodology

After multiple iterations, the tangible tokens have been tested in 12 semi-structured interviews with designers and sustainability experts of audio companies that produce connected speakers, headphones, and earbuds. The method is utilized in the last third of a 90-minute semi-structured interview. The interviews were recorded and partly transcribed. The researcher's observations and reflections after the interview sessions were the main information source.

**Figure 1. Tangible tokens.**

The first author of the study created the tangible tokens based on the framework presented in a previous study (Özcelik et al., 2022) that outlines existing concepts of product longevity in literature. In an initial test interview, we used paper mock-ups of the tangible tokens together with a drawing of one of the company's products to assess how well the participant grasped the concepts. After asking all initial questions, we showed three groups of codes and asked the participants which codes were related to their approach and how they impacted their work with examples. However, it became clear that the paper material and the drawings of the product did not work as we had hoped. The participants preferred to answer and discuss based on the real product rather than pictures of it or its components. However, the different longevity concepts broadened the discussions, and the participant brought more examples and insights having the stimulation of the tangible codes. For the final version we decided to produce codes on tokens made from MDF using a laser cutter (as can be seen in Figure 1). The longevity concepts are grouped into three main categories: design-related codes, software-related codes, and hardware-related codes and additionally another minor category: others. For each of these we used a different shape, the complete list of all used codes can be found in the table in the Appendix. Overall, the main objective was to present a range of concepts and to engage the participants as much as possible. These where then used in 12 semi-structured interviews. We present reflections based on these interviews below.

## Findings

### *Discussing the complexity*

Smart products have complex characteristics, particularly when viewed through the lens of longevity. They consist of identical components that are codependent on each other, requiring different approaches to ensure longevity. Discussing this complexity with participants can be challenging, but the use of tangible tokens has proven helpful in managing it. By presenting each category in the order of software, hardware, and product design, we were able to discuss the three layers of the product on equal footing.

In the interview conducted with the product designer from Company A, a medium-sized company, extensive discussions revolved around the product design-related codes, as the expertise of another individual who could address the software and hardware aspects was not included in the interview.

Consequently, the participant provided fewer details concerning the software and hardware elements compared to the product design-related codes. Conversely, in the case of Company B, a small-scale company, the interviewed participant held the dual roles of designer and company owner. Thus, being involved in design, software, and hardware matters, the participant was capable of presenting multiple examples and providing comprehensive explanations regarding all elements.

Having three main categories simplified the discussions. During the study, we noticed that discussing codes related to product design provided more insights compared to other categories. The relevance of this observation depended on the characteristics of the company and the level of responsibility of the participant.

***Stimulating the minds of participant***

Giving the material and using them as an elicitation technique, is described as “giving the pen to the participant” which releases some of the control over data (Sorensen et al., 2022). By giving participants more control over the data, researchers can increase the richness of the data and create a space for hands-on interaction with abstract concepts, leading to deeper reflections (Conrad, 2015).

Similarly, opening the conversations up and stimulating the participant to think was needed. Creating tangible tokens helped to stimulate participants to provide more specific and concrete examples regarding the various longevity concepts in three categories. In the interviews, we observed that more examples were brought forward by the participants during the tangible token part. As some participants preferred online interviews, we created a digital version of the tool in Miro. However, based on the researcher's observations, the physical version worked better and stimulated more reflections. In future studies, more space for the participant could also be created by providing empty tokens that they could fill themselves.

***Clarifying the framework of the study***

Even though longevity is a broad framework, there is a tendency to focus solely on particular longevity concepts, such as durability, quality, and robustness, and some sustainability concepts, such as recycled material, recycling, and carbon emission. Transferring the high variety of the concepts derived from the literature to the interviews helped researchers broaden the discussions and clarify the framework. Since our physical tokens are derived from the longevity literature, they might also in the future help researchers to compare academic and industry knowledge. It might allow us to go into detail about how companies apply academic concepts. Most significantly, it shows the line between academy and industry.

***Flexibility of the meanings***

Understanding the participant's point of view better reduces the researcher's bias and creates an opportunity to check how the concepts are used in an industry context. Tangible tokens, similar to card sorting activities (see Conrad, 2015), can be used in the semi-structured interview to increase shared understanding and reduce researcher bias, thereby decreasing misunderstandings.
Use of terminology was the biggest concern before starting the study, as longevity, sustainability, and circular economy are popular topics that can often be used with different meanings than those found in literature. We provided the longevity concepts to the participants without explanations and left the codes open to interpretation. The researcher only intervened if the participants asked about the codes' meaning. This approach made the participants' perceptions, meanings, and values explicit. Sometimes the concept was perceived differently than in the literature, but we did not interrupt the participants unless they asked for clarification, allowing them to attribute meaning. The following interview excerpt shows how researchers answered to the participant with the concern of impacting the participant.

Participant: *"Product, service and system, what could it be?” [participant takes the code and asks]*
Researcher: *“You have the product and a service around it.”*
Participant: *“Oh, we do not have that.”*

Furthermore, while showing the concepts, we did not provide any structure. Some participants preferred to have more structured keywords rather than the concepts themselves. *“Optimal lifetime [one of the code] is this aim or feature…its nice game you have it should have* *been more clear with the structure just as a recommendation and we say this is what we are this are not we are These are what we do or not I was confused some of the card or some of them not we don't but I have something to say about."*

All in all, although the lack of structure is addressed as an issue, tangible tokens helped the researchers to decrease the possibility of misunderstanding between the researcher and the participants.

## Conclusions

This paper introduced tangible tokens as a suggestion to collect data about the longevity of smart products and present the researchers' reflections.

Using tokens creates a vehicle for dealing with fluid terminology and subject complexity. The overall function of the approach was to be a framework that embodies, supports, and facilitates the identification of complexity and interdependencies of this inherently complex problem of longevity. Further, the method engages participants, allowing and promoting links between abstract concepts and concrete examples, thus facilitating a richer, more detailed, and operational outcome. It enables participants to become more explicit, clear, and reflective.

In conclusion, this paper highlights the potential benefits of using longevity-related codes in research. However, further development of the codes through a follow-up survey is recommended, and keywords have been provided for this purpose. The list of codes is accessible through the provided link and can be applied by design students in various contexts.

# A Review of Repurposing Lithium-ion Batteries for Household Applications

**Leander Pantelatos[(a)], Casper Boks[(a)], Elli Verhulst[(b)]**
a) Department of design, Norwegian University of Science and Technology (NTNU), Trondheim, Norway
b) Department of Industrial Economics and Technology Management, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

**Keywords**: Repurposing EV batteries; Second life batteries, Household applications; Lithium-ion batteries; User perspective.

**Abstract**: As global sales of electric vehicles are rising rapidly; vast amounts of end-of-life batteries are expected to need treatment in foreseeable future. Using second life batteries in lower demanding applications, could prolong the life of Lithium-ion batteries (LiBs), and in turn provide economic and environmental benefits. The household context is seen as a potentially huge market for second life batteries. This study tries to better understand the current state of repurposing batteries for household applications, by investigating 1) proposals for household applications, as well as their current market availability, 2) what are considered the main barriers for further commercial repurposing of EV LiB batteries, and 3) how design can contribute to extend the lifetime of EV batteries within household contexts. Findings indicate that repurposing LiBs for household applications proves to be technically feasible, provides environmental benefits. Several market offerings have been identified. Through the literature analysed, it is found that repurposing LiBs for household applications has mostly been investigated from a technical, economic, and business model perspective. Contributions addressing the end-user perspective remains a paucity – an important stakeholder within the household context.

## Introduction

Global Sales of Electric Vehicles (EVs) have risen exponentially in the past years (IEA, n.d.). As the Lithium-ion-batteries (LiBs) are usually abounded when the capacity has dropped below 80%, vast amounts of End-of-Life batteries (EoL) are expected to need treatment in foreseeable future. Current recycling processes are mature enough to be implemented in large scale, but still unable to recover all critical materials present in LiBs (Börner et al., 2022; Chen et al., 2019). As part of a circular loop, repurposing EoL batteries for less demanding applications presents itself as an attractive step in order to exploit the maximum economic value, whilst at the same time minimize the environmental impact of lithium-ion batteries (Harper et al., 2019).

Stationary Energy Storage Systems (ESS) has been proposed as such a suitable application Second-Life-Batteries (SLB), in both larger industrial scale systems and smaller residential applications (Hossain et al., 2019). As a shift towards a decarbonized future, the recent rise of renewable energy systems in the household sector, is foreseen to create a huge demand on energy storage solutions (Fernández Bandera et al., 2023). A task which repurposed LiBs could technically fulfil (Börner et al., 2022; Martín et al., 2022). The market is seen to be potentially huge (Cready et al., 2003; Zhao et al., 2021), and has the advantage of smaller to handle systems compared to their industrial scale siblings. Coming-of-age market examples within this context are Xstorage by Eaton, and the BeeBattery Home by Beeplanet factory.

Besides technical and economic aspects the end-user plays an important role in the adoption of new business models, which in the given context would be a homeowner or resident. Within the field of design, innovation and well-designed products – central elements in a business model - come from the intersection between economic viability, technical feasibility and desirability incorporating human aspects. Interdisciplinary design methodologies such as described by Buijs (2003), or design thinking (Brown & Katz, 2011), emphasises human aspects such as needs, context, values, problems and behaviours.

A fair body of literature addressing various aspects of repurposing LiBs has started to emerge (Hossain et al., 2019; Hu et al., 2022; Shahjalal et al., 2022). This study tries to better understand the current state of repurposing EV batteries for household applications, and how design can contribute to a further market upscaling. The goal of this paper is to determine the state-of-the-art scientific knowledge concerning 1) proposals for household applications, as well as their current market availability, 2) what are considered the main barriers for further commercial repurposing of EV LiB batteries, and 3) how design can contribute to extend the lifetime of EV batteries within household contexts.

## Method

The study is conducted as a literature review, including scientific and grey literature. A combination of relevant key words such as repurposing, remanufacturing, refurbishing, reuse, second life, batteries, household and residential were used. After an initial screening and removal of duplicates a total of 191 conference and journal articles were found. Using the inclusion criterion that articles had to address the second life of LiBs in household or residential applications, a set of 15 most relevant and recent articles were selected for the final analysis. Emphasis was put on household applications within the European context. Snowballing from the selected articles led to another 7 papers. The database Scopus was used for the analysis, because of general excellence coverage of industrial design, engineering, and technology research. Market offerings presented in Table 2 were found through the analysed literature and further searching on the internet.

## Background

### *From EV use to SLB*

Through charge/discharge cycles and operation condition of EVs, different ageing mechanisms are introduced inside an EV battery. A typical ageing trajectory is depicted in Figure 1. The trajectory is near to linear in the first stage, passing EoL at 80%. In the second stage, a non-linear degradation is introduced after reaching the knee point. Due to safety concerns such as thermal runway leading to explosions and fires, all utilization of the battery should cease when the knee-point is reached (Hu et al., 2022). As indicated in Figure 1, a substantial number of cycles are still possible after EoL, before reaching the knee point (Hu et al., 2022). The total number of cycles before the knee point is also dependent on factors such as operating conditions in the first life, and battery chemistry (Hu et al., 2022; Martinez-Laserna et al., 2018).

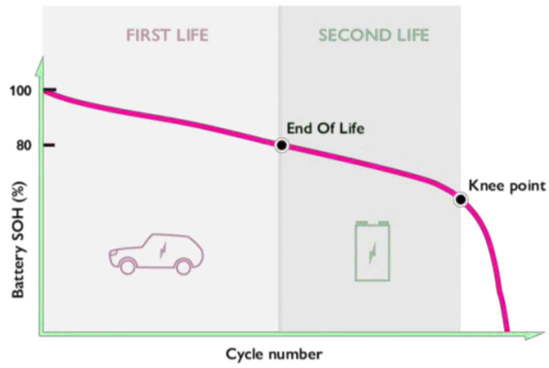

**Figure 1. Ageing trajectory of LiBs. Adapted from Hu et al., (2022).**

At the EoL stage, LiBs are inspected and tested. Then a decision is made whether the battery pack should be reused, remanufactured, repurposed or recycled (Börner et al., 2022), based on SoH and lifetime expectancies. In the process of repurposing, the depth of disassembly (whole pack, module or cells) would impact cost, efficiency and safety (Hu et al., 2022). In a lower degree of disassembly, several components could also be reused, such as housing, busbars, battery management system (BMS) etc. (Montes et al., 2022). Direct repurposing of whole battery pack, being the most economically favourable option, would on the other hand provide uncertainty about the state of the modules and cells inside, which might lead to a shorter second life and cause safety concerns (Hu et al., 2022).

There are several uncertainties within the process of an EV battery emerging into a second life application. Montes et al. (2022) have developed a framework for battery assessment after first life which includes three stages (1) battery state evaluation, (2) evaluation of the technical viability of different solutions and (3) economic evaluation. Ideally one would seek for applications with a lower cycles rate and less power demands, which for example an ESS in a household context would represent.

## Findings

*Applications in research*

This section presents applications studied and described in literature. In the context of household applications, it is found that repurposing LiBs as stationary storage for energy-time-shift strategies can help to reduce energy costs and relieve the electricity grid. According to the studies included in this work, the most promising solution seems to be a combination of ESS systems with photovoltaic (PV), as this allows households to maximise self-consumption. Table 1 gives an overview of relevant studies on ESS applications, mostly within the European context.

All studies analysed in this paper, investigated repurposed libs as energy storage within the household/residential context. Heymans et al., (2014) finds that a single ESS can shift the total energy consumption of 2-3 hours and calculates the benefits of peak-shaving on household level to be huge in grid scale. Repurposed libs as ESS are found to be technically feasible through several studies. Philippot et al. (2022) finds that an EoL of NMC-LTO chemistry can be used as an ESS for another 10 years, while Thakur et al. (2022) finds the extended lifetime to be 3-5 years in different combinations of vehicle to grid, PV and feed-in-tariffs. On the economical side, using repurposed ESS solely for load-shifting is found to be marginally profitable, and would to a large degree rely on governmental incentives in a Canadian context studied by Heymans et al. (2014). Repurposed batteries along with PV is found to have economic benefits for the homeowner, according to Assunção et al., (2016); Thakur et al., (2022). Nevertheless, there are notable discrepancies in cost calculations for the repurposing process of SLBs (Montes et al., 2022) and profitability (Martinez-Laserna et al., 2018). On an environmental note, Philippot et al. (2022) finds the second life duration, share of qualified batteries and the carbon footprint of the electricity mix to be important factors when considering reuse in EV vs repurposing. The repurposed ESS capability of household peak shaving and thereby reducing the use of gas-based peak-power is highlighted by Heymans et al., (2014); Martinez-Laserna et al., (2018) and Thakur et al., (2022) as another environmental benefit.

*Applications in practice: examples of relevant market offerings*

Several offerings based on repurposed batteries for the household context, are identified. Table 2 gives a non-exhaustive overview over examples of relevant business cases. Some of the cases have been identified through literature, but in order to provide an updated list, the list has been revised and expanded through resorting grey literature and the web. In line with the applications in research, most of the offerings are proposed for the ESS use case. One case is specifically targeting the Norwegian cabin market, which often are off-grid and relying on electricity by PV. An interesting concept is betterPack by Betteries, which provides a modular solution that can be used to power a variety of applications, such as electric vehicles, boats and replace generators in outdoor contexts. The case is not specifically targeting private households, but the offering is seen to be conceptually relevant. The company Hagal does not specifically address the household market but is included because of their new technology monitoring individual cells for better performance and safety (Bjørheim, 2022) which is seen to be relevant to the context of households.

Kielland & Skibstad (2022) interviewed manufacturers of SLBs in Norway, many offering solutions for the household context. It is found that the actors seemingly have managed to establish a customer base for their solutions. The main barriers pointed out in a Norwegian context, are the lack of market structure and national regulatory standards. Some of the actors also shares that they made a strategic choice to maintain a low price in order to get acquainted with the market and to attract customers. A low price whilst maintaining R&D activities, is made possible either by or in combination of public support systems, investors, and having other profitable branches (Kielland & Skibstad, 2022)

| Relevant Use Case | Authors | EV Battery and Size | Method | Relevant findings | Region |
|---|---|---|---|---|---|
| Two scenarios for EOL LiBs investigated through LCA assessment: (1) SLB storage with PV in a Belgian Household and (2) reuse in EVs. | (Philippot et al., 2022) | Fiat 500x<br><br>7,6 kWh | Ageing test of NMC-LTO cells and empirical studies to model battery behaviour. ### *Barriers and challenges*

In the literature analysed, several barriers to a further market upscaling of repurposing LiBs for the household context have been identified (Table 3). The barriers and challenges are categorized into four levels from a household perspective: legislative, technological, market, and user.

On a legislative level, a lack of standards and regulations are seen to be an important barrier (Hossain et al., 2019; Hu et al., 2022; Jiao & Evans, 2018; Martinez-Laserna et al., 2018). This is also evident on a technological level, where a huge variety of types, forms, chemistries, and proprietary systems and information makes it difficult to achieve an efficient repurposing process according to Börner et al., (2022); Hossain et al., (2019); Reid & Julve, (2016). Several authors highlight the challenge of accurate Remaining Useful lifetime (RUL) predictions (Hu et al., 2022; Martinez-Laserna et al., 2018; Shahjalal et al., 2022), as this is seen to be vital ensuring safe and reliable operation of an SLB. Ineffective RUL predictions does also limit warranties and challenges liability (Börner et al., 2022; Bräuer, 2016). On a market level, repurposing costs are seen as an important barrier (Kielland & Skibstad, 2022; Montes et al., 2022). These are found related to a high degree of manual labour (Börner et al., 2022; Hu et al., 2022), and huge transportation costs due to the hazardous nature of Libs (Hossain et al., 2019; Jiao & Evans, 2018), amongst others. Safety is found to be another critical barrier as the high safety requirements for the operation in an EV would not change in second life operation within the household context (Börner et al., 2022), which is costly to ensure. Furthermore, (Shahjalal et al., 2022) underlines the availability of EoL batteries in need to be sufficient, and that an efficient production line and business models must be in place for a further upscaling of the repurposed LiB market.

The price fall of fresh batteries is indicated to become a potential barrier on a market level (Henze, 2022; Hossain et al., 2019), but is also seen to become a possible barrier at the user end. Shahjalal et al. (2022) argues that customers would rather choose new batteries when neglecting the environmental benefits of repurposed LiBs. According to Börner et al., (2022); Bräuer, (2016), a reduction in price must be given to the end-user for the disadvantage of reduced energy density and service life compared to new ones. Related to the safety aspect above, Börner et al. (2022) also exemplifies the consequences of a battery failure by referring to the Samsung Galaxy Note 7 case. The smartphone model had a battery design error that for some devices led to fire during charging. The product was taken of the market, and damaged customer trust.

| Categories | Barrier description | Sources |
|---|---|---|
| Legislative | Lack of regulations and standards. | (Hu et al., 2022; Jiao & Evans, 2018; Martinez-Laserna et al., 2018) |
| Technological | Variable battery design, chemistry, and management system.<br>Lack of design for disassembly.<br>Lack of technology to perform automated repurpose process.<br>High optimization for first life leads to mismatch for second life requirements.<br>Unclear remaining useful lifetime, after EOL. | (Hossain et al., 2019; Martinez-Laserna et al., 2018; Montes et al., 2022)<br>(Börner et al., 2022; Jiao & Evans, 2018)<br>(Hu et al., 2022). |
| Market / SLB Repurposer | Battery availability.<br>Price reduction of the new batteries.<br>Transportation costs.<br>Disassembly and repackaging costs.<br>Liability.<br>Limited data sharing between OEMs and repurposers. | (Shahjalal et al., 2022)<br>(Hossain et al., 2019)<br>(Montes et al., 2022; Zhao et al., 2021)<br>(Börner et al., 2022; Jiao & Evans, 2018) |
| User | Safety and reliability uncertainty.<br>Lack of awareness and information.<br>Scepticism towards “used products”.<br>No incentives for using repurposed batteries, as is the case for other domestic green technology solutions (example from Norway). | (Börner et al., 2022; Hu et al., 2022)<br>(Elkind, 2014; Shahjalal et al., 2022)<br>(Jiao & Evans, 2018)<br>(Kielland & Skibstad, 2022) |

**Table 3. Barriers for second life in household applications.**

Consequently, the recall and lower sales figures led to Samsung loosing operating profits by 96% in the mobile division 2016 and shocked the whole mobile phone branch by reduced sales of 15% in 2016 (Edwards, n.d.). The case exemplifies that hazardous events can have severe negative impacts on stakeholders and highlights the effect of perceived trust. On a general note, Bräuer,(2016) calls for research addressing the challenges on the customer related to SLBs in the household context.

## Potential solutions

A variety of potential solutions to the barriers above have been proposed in the analysed literature. Proposals such as the New EU regulatory framework for batteries (Halleux, 2021), which would require information on specification, and current state of the individual LiB to be easily accessible, is seen to have potential on the legislative level. On the technological level., cloud-based data gathering methods for RUL estimations as proposed by Li et al., (2021), and automated disassembly Zang & Wang (2022), could make the repurposing process more efficient, which also would benefit the market by reduced costs. Investigations of different business models is also found in i.e. Jiao & Evans (2018). These solutions would also address many of the barriers stated on the user level, nevertheless no material directly addressing the user is found in the analysed literature.

## Discussion and Conclusions

Through the literature analysed, the household market is presented as potentially big, and a technically feasible way to locate EoL LiBs after an initial life in an EV, whilst providing environmental benefits before moving further to recycling. From a technical perspective, several studies have shown the feasibility of energy time shift and enhancing electricity self-consumption. From an economical perspective, studies i.e. (Assunção et al., 2016; Thakur et al., 2022) show that a combination with PV could provide savings for the homeowner. However, there is still uncertainty on the economic feasibility. Several examples of offerings have been identified, but these are arguably still to be seen as emerging.

Several challenges are recognized in literature on four different levels: legislative, technological, market and user (Table 3). Simultaneously literature also describes possible solutions, mostly on the technological and market level. Acknowledging that work is also being done on the legislative level, comparatively little research and insights can currently be found on the user level.

The success of business models concerning repurposed LiBs in a household context will largely depend on user acceptance, both objective and subjective perceptions taken into account. This comes forward in the current literature to the extent where only the lack of contributions on the user side in the development of a product-service system for repurposed electric vehicle batteries is mentioned (Bräuer, 2016). In the research studies analysed in this paper, the user is arguably seen as a consumer only considering the most profitable option in a specific context. But there are several aspects to consumer behaviour which are not addressed, as for instance needs, habits perceived benefits and perceived risks etc. Design research offers to investigate such perceptions and can inform business models to steer and focus offerings towards specific applications and user groups. The market example of Betteries would suggest that there are further applications than SLBESS for extended self-consumption, peak shaving and load levelling. The perceived safety aspect as indicated by (Börner et al., 2022), exemplifies the need for subjective factors to be taken into account. Furthermore, user research can investigate intrinsic and extrinsic motivations in order to raise awareness and desirability for SLB products, highlighted as important by Elkind (2014). By investigating the user perspective, business models can be informed to develop repurposed lithium-ion battery offerings that meet the specific needs and expectations of household users while ensuring safety and performance. This can lead to a more successful adoption of repurposed batteries in the household context, benefiting users, markets, and the environment.

## Acknowledgements

This research is funded by HoLe-LiB project (Developing a Holistic Ecosystem for Sustainable Repurposing and/or Recycling of Lithium-ion Batteries (LIBs) in Norway and EU) at the Norwegian University of Technology and Science (NTNU).

# Young Danes dressing the part: A heedless or mindful use phase?

**Morten Krogh Petersen**
Design School Kolding, Kolding, Denmark

**Keywords**: Material-semiotic approaches; Use; Everyday Life; Practice; Sustainability; Fashion and Clothing.

**Abstract**: This paper provides an analytical contribution to the research field of sustainable fashion consumption by outlining a material-semiotic approach. This material-semiotic approach is contrasted with the presiding behavioral approaches through two analytical moves: 1. from individual choice to everyday practices, and 2. from implications for design to practice-oriented design. The two analytical moves are illustrated through two teaching-based research collaborations, which both sought to understand better how design research might come to influence the development of more sustainable practices of dressing the part over space and time.

## Introduction

As an analytical contribution to the research field of sustainable fashion consumption, this paper sketches out a material-semiotic approach to the so-called use phase of clothing and fashion items. Material-semiotic approaches prompt us to understand “everything in the social and natural worlds as a continuously generated effect of the webs of relations within which they are located. It assumes that nothing has reality or form outside the enactment of those relations” (Law 2009: 141). In our case, this entails the following proposition: Neither clothing and fashion users nor clothing and fashion items have any stable identities outside of the situated socio-material practices in which they are enacted (see also Capelan Köhler 2017). Reality, in other words, “does not precede the mundane practices in which we interact with it, but is rather shaped within these practices” (Mol 1999: 75, see also Mol 2002). Material-semiotic approaches, thus, enable analytical inquiries into the making and unmaking of sustainable fashion consumption in and through socio-material and collaborative everyday practices.

## Dressing the part

The notion of ‘dressing the part’ is an attempt at bringing the field of sustainable fashion research into dialogue with such material-semiotic approaches. First, ‘dressing the part’ – rather than, for instance, ‘getting dressed’ – stresses that how we as humans get dressed is never purely a matter of a human individual making an individual choice. We suggest, instead, that how human individuals dress the part is, for instance, formed by and forming socio-materially enacted conventions, including specific ideas of comfort and cleanliness (Shove 2003). Dressing the part is accomplished in and with various other everyday practices and materialities, which dis- and enable specific ways of dressing the part. Everyday practices should, thus, not be understood as individual unconscious habits, as behavioral approaches might suggest, but as semi-conscious (Dryfus 2017) and socio-materially enabled routines, experiments, and events (Petersen 2022). Second, engaging with the use phase with material-semiotic approaches leads not to straightforward “implications for design” (Dourish 2006), as this would exactly imply the existence of stable human, social, and material identities (see also Latour 1994). Material-semiotic approaches, instead, prompt sustainable fashion consumption research on how design researchers might come to connect themselves to and “amplify” (Manzini 2015) existing and ongoing mundane experiments in and tinkering with enacting more sustainable everyday practices of dressing the part.

We develop our argument in two parts: First, we discuss the move from individual choice to everyday practices. Second, we consider what kinds of sustainable fashion research are required to unleash the potential of material-semiotic approaches, suggesting practice-oriented design as a valuable avenue to explore further. The two analytical moves are both introduced through experiences gained in two studies conducted as teaching-based research collaborations (Damsholt & Sandberg 2018).

## From individual choice to everyday practices

It's early spring 2022. As part of a master's course in design methodologies for design master's students at the Design School Kolding (DSKD) and design management students at the University of Southern Denmark (SDU), we, the teachers, have partnered with Kolding Municipality's House of Sustainability. The House of Sustainability is a hub for all sustainability-oriented initiatives in the municipality.

In setting up the partnership, we, the teachers, tell representatives from the House of Sustainability that we would like to take everyday practices – different from the more commonly explored phenomenon of consumer behavior – as our unit of analysis and design. We do so, as there are already plenty of institutions developing recommendations on how individuals might behave greener. The impact of these recommendations is limited. We suspect that the reason is that these recommendations are not developed in and with everyday life (Damsholt & Jespersen 2014). Less is known, in other words, about how the everyday use of clothing unfolds and how such everyday use practices develop, are sustained, or wither away. We settle on three more aspects of our partnership: To focus on young Danish adults (16-30 years old), to complete an open design brief together, and to give the students the creative obstruction of manifesting their work in material artifacts, designed to spark conversations (Buur & Larsen 2010) on how sustainable clothing practices might come to be innovated and unfold in young Danes' everyday lives.

During the initial lectures and classes, preparing the students for their first encounters with their young interlocutors, we, the teachers, stress: When you engage with your young interlocutors, don't start by asking "why?" they dress as they do. Start by asking "how?" they get dressed. We do so, as we are less interested in our interlocutors' logical reasonings and convincing explanations of why they get dressed as they do, and more interested in the daily practicalities dressing the part (Becker 1998).

This methodological trick of asking "how?" instead of "why?" generated empirical materials depicting dressing the part as arduous work. Arduous, everyday work of buying new items while contemplating if the items are suitable for re-selling and at what price later on. Arduous work of noticing and learning, which kinds of materials hold up to laying on the couch at night and which definitely do not. Arduous work of enrolling a bathroom floor as a materiality upon which, at night, the outfit worn throughout the day can be laid out and decisions about what needs and doesn't need to be washed to the morning after. Arduous work of not being seduced by that influencer to buy that item – however tempting. This arduous work is not purely human and individual accomplishments but performed in and with a host of other kinds of actors, including smartphones and the easy access to projected re-selling prices that these provide, bathroom floors, influencers, and, not to forget, the fashion and clothing items and their vibrancy (Bennett 2010).

Material-semiotic approaches stress that the human individual is never alone. Therefore, material-semiotic approaches are well-suited to question some of the ontological and theoretical commitments of prevailing research into how one might come to 'sustainabilize' the consumption of fashion and clothing items (for two recent reviews, see Busalim et al. 2022 and Dabas & Whang 2022). This questioning is essential, as nothing indicates that research on sustainable fashion research has cracked the code of how to transition towards more responsible clothing consumption practices.

To understand everything as effects of the continuous relating of human and non-human actors in mundane everyday practices questions the dominant idea that if we wish to 'sustainabilize' fashion and textile consumption, we must understand better and devise ways of closing "the consumer attitude-behavior gap" (Busalim et al. 2022: 1814, see also Dabas & Whang 2022). The idea of this gap – which is also named the "'value-action gap'" (Shove 2010: 1276, see also Blake 1999) and the "knowledge-action gap" (Knutti 2019) – has utterly reductionist implications for how we might come to develop new and less resource-demanding ways of living with clothing. As sociologist Elizabeth Shove has argued, "framing the problem of climate change as a problem of human behavior," that is, the problem of misalignment between individual human attitudes and individual human behavior, "marginalizes and in many ways excludes serious engagement in other possible analyses" (Shove 2010: 1274).

What might these "other possible analyses" be, and what is their *modus operandi*? Let us begin to answer these questions through a second teaching-based research collaboration.

## Form implications for design to practice-oriented design

It's the beginning of autumn 2022. In a master's course in designerly practice and theory, part of the master's program in Design Management offered in collaboration between SDU and DSKD, we, the teachers, have partnered with the Danish men's fashion brand, NNO7, and the Danish software company, UpChannel. NN07 designs "responsibly made-to-last products with attention to the needs of today and tomorrow" (www.nn07.com, accessed 29 March 2023). UpChannel offers a blockchain-powered solution that enables companies and brands to deliver information about the climate and environmental production costs of their products by consumers scanning a QR code (www.upchannel.eu, accessed 2 April 2023). Both companies would like to know more about how much and what kind of information the consumers find valuable. UpChannel with a particular interest in how to get the consumers to scan the QR code, and NNO7 with a particular interest in how UpChannel's or similar solutions might enable the company to gain information about the use phase.

While the first partnership was methodologically primarily inspired by design anthropology (Clarke 2017, Miller 2017), we here operated a design methodology focusing on the dialectic between design experiments and programs, also known as programmatic design research (Brandt et al. 2011, Bang & Eriksen 2014). While much design anthropological work definitely seeks to go beyond utilizing qualitative research to provide some kind of business empiricism (Jespersen et al. 2012), it does risk, in practice, to be enacted as anthropology for design, upholding the linear idea that, first, we need to understand the world and, then, design for it (Gunn 2020, Murphy 2016). Programmatic design research more directly positions design practices and development "smack in the middle of everyday life itself" (Halse et al. 2010: 15), allowing for a more iterative approach.

Over the following weeks, the students' work is progressing quite nicely, we, the teachers, assess. But many of the students display a body language of wretchedness. Why? During their design experiments, their young interlocutors tell the students that they dislike discussing sustainable clothing and fashion. The young interlocutors argue that the notion of 'sustainability' is everywhere, leaving it somewhat meaningless to them. Clothing and fashion businesses promote their offerings as sustainable, but the young interlocutors perceive such promotions as the businesses' own business. The students tell us, their teachers, that their young interlocutors are less interested in what clothing and fashion businesses say they do in terms of sustainabilizing their offerings, as the young interlocutors expect this to be a matter of regulation by law. What interests them, however, is how they can actually and practically come to contribute to sustainable transitions in clothing and fashion consumption. The students' wretchedness, then, was an outcome of engaging with everyday practices, which rendered the partnering companies' wishes to provide more information on the production phase to the young consumers somewhat off the mark.

A group of students told us that what preoccupied their young interlocutors was not sustainability per se but the quality of their fashion and clothing items. We, the teachers, suggested to this group of students that they regard their interlocutors' mundane involvements in the quality of their fashion and clothing items as "accidentally sustainable" (Woodward 2014) innovations in their clothing practices, which they should explore further and find ways of amplifying. Further, we urged the students to explore how the quality of clothing and fashion items might enable new kinds of sustainabilizing "prehensions" (Haraway 2003: 6) between consumption and production. Such prehensions seemed possible and desirable, as quality is not only a "matter of concern" (Latour 2004) in the everyday life of their young interlocutors, but also in the daily operations of a fashion brand like NN07.

In this case, then, we did not aim to understand the young interlocutors' attitudes, behaviors, and choices regarding their consumption of clothing and fashion items, and to develop implications for design from such an understanding. Rather, we asked the students to engage in what sociologist Elizabeth Shove has termed practice-oriented design (Shove et al. 2007). Shove contrast this particular design strategy of practice-oriented design with product- and user-centered design strategies. She suggests that practice-oriented design "changes the relevant unit of analysis and enquiry: rather than persisting with user studies or with market research, designers and their clients might look for ways of understanding and influencing the evolution of practice over space and time. This is not as strange as it might sound, after all, effective product innovations are in any case almost certainly connected to innovations in practice (Shove and Pantzar 2005)" (Shove et al. 2007: 135). Relating this point to our discussions of quality: We were looking for ways of understanding and connecting the quality practices of consumers and producers, as this might help us all to influence and further the evolution of more sustainable practices of dressing the part over space and time.

## Concluding remarks

The global production and consumption of clothing and fashion items are still very much on the rise. On this bleak background, this paper has taken issue with the dominant behavioral approach to sustainable fashion consumption by introducing an alternative, material-semiotic approach. The reason for this endeavor is simple: if sustainable fashion consumption was simply a matter of individual consumer attitudes, behaviors, and choices, and if these attitudes, behaviors, and choices could simply be re-design by providing more information to the consumers, then we would not be in a situation where the global production and consumption of clothing is still very much on the rise. Material-semiotic approaches, by contrast, decenter the human individual and ask us instead to engage with how realities are enacted in collaborative and mundane socio-material practices. Using two teaching-based research collaborations as our empirical examples, we have shown how such a material-semiotic approach, first, is well-suited to understand the arduous and mindful work performed in the use phase, and, second, how it prompts us to develop more sustainable practices of dressing the part by connecting practices of consumption and production through shared matters of concern such as the quality of clothing and fashion items.

## Acknowledgments

I wish to thank our external collaborators: Kolding Municipality's House of Sustainability, NN07, and UpChannel for their engaged participation. And all of the students involved in the two studies, especially design management students Nina Bruun, Troels Torp, Natalie Bernberg Christensen, Manmohan Kaur Ghuman, and Kadja Hansen for their brilliant work on quality.

# Scope and relevance of circular economy indicators for the sustainable lifetime management of batteries for electric vehicles

**Aitor Picatoste[(a)], Dani Justel[(a)], Joan Manuel F. Mendoza[(a,b)]**
a) Mondragon Unibertsitatea, Faculty of Engineering, Mechanics and Industrial Production, Loramendi 4, Mondragon 20500 Gipuzkoa, Spain
b) Ikerbasque, The Basque Foundation for Science, Plaza Euskadi 5, Bilbao 48009 Bizkaia, Spain

**Keywords**: Circularity; Circular design; Electric mobility; Electric vehicle battery; Life cycle management.

**Abstract**: Circular economy (CE) is aimed at improving resource efficiency to reduce the environmental burden and other negative externalities of production and consumption systems. Focusing on batteries for electric vehicles (EV), various CE strategies can be applied to improve manufacturing efficiencies, develop long-lived products or facilitate life-extension, and enable material reuse and recycling at the end-of-life. However, product design methods not relying on the consideration of CE criteria and indicators could lead to insufficient resource efficiency improvements or undesired consequences, such as rebound effects. This is important because batteries can account for over 40% of the EVs´ life cycle environmental impacts. However, the literature analysing the applicability of CE indicators to EV battery design and management is scarce and limited in scope. This study evaluates 15 product-level CE indicators to determine its importance and viability to inform battery designers and manufacturers in the development of more sustainable products. An Excel-based matrix was built to provide a description of each CE indicator, including its applicability, scoring system and data requirements, and show their links to the hierarchy of CE strategies and life cycle stages. The suitability of the CE indicators to support decision-making was evaluated by ten industrial stakeholders (manufacturers of battery components). The results show that End of Life Indices (Favi et al., 2016) and the Product Circularity Indicator (Bracquené et al., 2020) are the most suitable indicators due to the quality of information provided. However, it is crucial to develop new battery-oriented circular design methods and indicators to support the development of sustainable EV batteries.

## Introduction

Electric vehicles (EV) are being deployed worldwide as a key technology solution to decarbonise urban mobility in cities and regions (European Commission, 2019). Nonetheless, EV contribute to multiple environmental impacts, especially due to the influence of the batteries (Xia & Li, 2022).

Resource consumption in battery manufacturing and the energy consumed during operation are important aspects contributing to the environmental impacts of the EVs (Picatoste et al., 2022b). Moreover, critical raw materials(European Commission, 2023) such as cobalt, copper, lithium, manganese, nickel or graphite are key elements for the production of EV batteries and their increased future demand of can stress further supply chain constraints (Carrara et al., 2023).
Therefore, the implementation of circular economy (CE) strategies, aimed at reducing resource use, prolonging and intensifying the use of products and recovering materials from waste streams (Bocken et al., 2016) is key to improve the environmental performance of EV batteries (Baars et al., 2020). The integration of CE in the circular design of EV batteries has been recently explored by Picatoste et al. (2022a) who highlights that design criteria are required to be implemented to improve the EV batteries lifetimes. However, suitable metrics are needed to avoid potential trade-offs as lowering recycling indices due to lifetime extension strategies or risking the durability of the EV battery by excessive lightweighting.

CE indicators are measuring instruments to specifically analyse the transition towards more circular practices (Saidani et al., 2019) and are aimed to support the design and management decision-making (EMF & Granta design, 2015). Scholars and industry experts emphasise the importance of using CE indicators to assess the sustainability performance of EV batteries´

supply chains (Gebhardt et al., 2022). Likewise, the analysis of product-level CE indicators for EV batteries is yet scarce in the scientific literature. This limits the knowledge of available standardised metrics for the assessment of circularity of EV batteries and to support design and management decision making.

Therefore, the objective of this article is to evaluate the perception of industrial stakeholders (designers and manufacturers of batteries for EVs) on the importance and viability of using CE indicators for the design and development of more resource-efficient EV batteries, and to ultimately identify the most suitable indicator(s) for consideration in circular design processes.

## Methodology

Figure 1 presents the four-step methodology applied for the selection, documentation and evaluation of CE indicators by the industrial stakeholders.

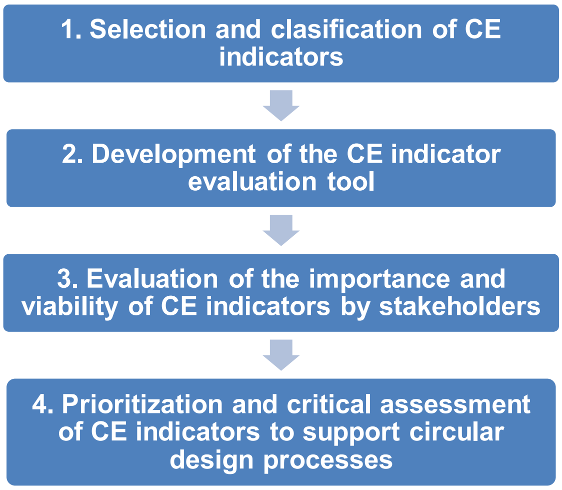

**Figure 1. Research methodology. Acronyms: CE (circular economy).**

### *Selection and classification of CE indicators*

A SCOPUS search was performed using the four search streams: CE, indicator, battery and electric vehicle and synonymous.

This search yielded 39 hits. However, only one of the articles explicitly proposed or applied CE indicators to analyze the circularity of EV batteries (Schulz-Mönninghoff et al. (2022) using Material Circularity Indicator (MCI) (EMF & Granta design, 2015)and Circularity Transition Indicators (WBCSD, 2021), although at the company- rather than the product-level.

To complement the literature search, six recent and highly cited literature reviews on CE indicators were analysed to identify suitable product-level indicators for the analysis of the circularity of EV batteries (Corona et al., 2019; de Oliveira et al., 2021; Jerome et al., 2022; Kristensen & Mosgaard, 2020; Lindgreen et al., 2022; Saidani et al., 2019).

Finally, the European battery regulation (European Commission, 2006; Halleux, 2022) and the PEFCR (European Commission, 2018) were also reviewed for possible CE indicators.

This resulted in the identification of 127 CE indicators. However, CE indicators for evaluation were selected by applying the following criteria:

- Only consider product-level indicators (micro or nano level).
- CE indicators non-applicable to lithium-ion EV batteries were discarded.
- If a CE indicator had an updated version, the previous one was discarded (e.g. Longevity indicator from Franklin-Johnson et al. (2016) vs Longevity and Circularity indicators from Figge et al. (2018)).
- CE indicators with a qualitative approach were discarded.
- CE indicators not directly available for the user were discarded (e.g., Circular economy indicator prototype (CEIP) (Cayzer et al., 2017), an excel spreadsheet that is provided by the authors after personal request).

Accordingly, 15 indicators were selected and classified according to the life cycle stage (Manfredi et al., 2012) and the CE strategy (Blomsma et al., 2019) as shown in Table 1.

| Name of indicator and reference | Life cycle stages | | | | | Circular Economy strategies | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Raw material | Manufacturing | Transportation | Use phase | End of life | Reduce | Upgrade | Repair | Reuse | Refurbish | Remanufacture | Repurpose | Recycle | Cascade | Recover |
| Product Circularity Indicator (PCI) (Bracquené et al., 2020) | x | x | | x | x | x | | x | x | x | x | | x | x | |
| Longevity and Circularity indicators (Figge et al., 2018) | x | | | x | x | x | | x | x | x | x | x | x | x | |
| Circularity Index (CI) (Cullen, 2017) | x | x | | | x | x | | | | | | | x | | x |
| Multidimensional Indicator Set (MIS) for WEEE (Nelen et al., 2014) | x | x | | | x | | | | | | | | x | | |
| End of Life indices (EoLi) (Favi et al., 2016) | x | x | x | | x | | | | x | x | x | x | x | x | x |
| Circular Economy Index (CEI) (Di Maio & Rem, 2015) | x | | | | x | | | | | | | | x | x | x |
| Product-Level Circularity Metric (PCM) (Linder et al., 2017) | x | x | x | | x | | | | x | x | x | x | x | x | x |
| Global Resource Indicator (GRI) for life cycle impact assessment (Adibi et al., 2017) | x | | | | x | x | | | | | | | x | | x |
| Reuse Potential Indicator (RPI) (Park & Chertow, 2014) | | | | x | x | | | | x | x | x | x | x | x | |
| Resource Efficiency Assessment of Products (REAPro) (Ardente & Mathieux, 2014) | x | | | | x | x | | | x | x | x | x | x | x | |
| Recycling Rates (Haupt et al., 2017) | | | | | x | | | | | | | | x | x | |
| Circular Product Index (CPI) (Saidani et al., 2019) | x | x | | x | x | x | | x | x | x | x | x | x | x | x |
| Net losses of metals (Söderman & André, 2019) | | | | x | x | | | | x | | | x | x | x | x |
| The Circular Footprint Formula (PEFCR) (European Commission, 2018) | x | x | | | x | x | | | | | | | x | x | x |
| The Circular Economy Performance Indicator (CPI) (Huysman et al., 2017) | x | | | | x | | | | | | | | x | x | x |

**Table 1. List of selected indicators, classified by the life cycle stages and circular economy strategies analysed.**

*Development of the CE indicator evaluation tool*
An Excel-based tool was built to list, describe and share the selected CE indicators for evaluation by the industrial stakeholders, following the approach provided by Picatoste et al. (2022a) for the evaluation of circular design criteria.

Each indicator was described, including applicability, score system and link to CE strategies and life cycle stages, and this information was used to ask the industrial stakeholders to evaluate the suitability of each indicator according to the following considerations:

i) Importance (0 to 9): how relevant the indicator is to support decision-making processes for the circular design and sustainable management of EV batteries.
ii) Technical viability (0 to 5): how easy is to gather the required data and perform the required calculations.

By multiplying the corresponding importance and viability scores, the resulting number was considered the suitability category (0 to 45) of the indicator to determine circularity performance of alternative battery design choices to support decision-making.

*Evaluation of the importance and viability of CE indicators by stakeholders*
European designers and manufacturers of batteries were contacted via e-mail and invited to participate in the evaluation and, upon agreement, the CE indicators evaluation tool was shared.

Instructions to fill the evaluation tool were included both in the e-mail and the evaluation tool itself. To complement this interaction, stakeholders were offered a 1-on-1 online meeting for further explanation (30') or a "guided evaluation" (90') in which the stakeholder was accompanied in the process of filling the tool by the authors of this paper who acted as facilitators.

In total, 10 stakeholders of the European EV battery industries, participated in the evaluation of the CE indicators, providing data and comments.

*Prioritization and critical assessment of CE indicators to support circular design processes*
After the interaction with stakeholders, results were gathered to obtain average scores for all three categories, and classified according to the percentage of the maximum score obtained for each category (9 for importance, 5 for viability and 45 for suitability)

The most and least important and viable CE indicators were found and the reasons for those scores explored, which lead to the analysis of pros and cons for each indicator and the key factors to improve and define the most suitable CE indicators for EV batteries.

## Results
Table 2 lists the average results regarding the evaluation of the CE indicators by the industrial stakeholders.

| Name of indicator and reference | Imp. | Viab. | Suit. |
|---|---|---|---|
| End of Life indices (EoLi) (Favi et al., 2016) | 61% | 44% | 22.4% |
| Product Circularity Indicator (PCI) (Bracquené et al., 2020) | 68% | 38% | 21.5% |
| Circularity Index (CI) (Cullen, 2017) | 51% | 48% | 20.4% |
| Circular Product Index (CPI) (Saidani et al., 2019) | 67% | 36% | 20.0% |
| Circular Economy Index (CEI) (Di Maio & Rem, 2015) | 44% | 52% | 19.3% |
| Longevity and Circularity indicators (Figge et al., 2018) | 54% | 38% | 17.2% |
| Recycling Rates (Haupt et al., 2017) | 48% | 42% | 16.7% |
| Product-Level Circularity Metric (PCM) (Linder et al., 2017) | 46% | 42% | 15.9% |
| Resource Efficiency Assessment of Products (REAPro) (Ardente & Mathieux, 2014) | 54% | 34% | 15.4% |
| Multidimensional Indicator Set (MIS) for WEEE (Nelen et al., 2014) | 56% | 32% | 14.8% |
| The Circular Footprint Formula (PEFCR) (European Commission, 2018) | 61% | 28% | 14.3% |
| Net losses of metals (Söderman & André, 2019) | 46% | 34% | 12.9% |
| The Circular Economy Performance Indicator (CPI) (Huysman et al., 2017) | 54% | 26% | 11.8% |
| Global Resource Indicator (GRI) for life cycle impact assessment (Adibi et al., 2017) | 39% | 32% | 10.4% |
| Reuse Potential Indicator (RPI) (Park & Chertow, 2014) | 26% | 36% | 7.7% |

**Table 2. Average scores per category for each CE indicator, as a percentage of the max. score.**

### *Importance of CE indicators*

Four CE indicators were considered of high importance (>60%): Product circularity indicator (PCI) (Bracquené et al., 2020), Circular Product Index (CPI) (Saidani et al., 2019), End of Life indices (EoLi) (Favi et al., 2016), The Circular Footprint Formula(European Commission, 2018).

The main reason for this high importance score was the completeness of the CE indicators, covering multiple life cycle stages and CE strategies (Table 1) to support design decision processes.

### *Viability of CE indicators*

Regarding the viability scores, five indicators were considered medium viable (>40%). For the Circular Economy Index (CEI) (Di Maio & Rem, 2015), Circularity Index (CI) (Cullen, 2017), Product-Level Circularity Metric (PCM) (Linder et al., 2017) and Recycling Rates (Haupt et al., 2017), the ease of data gathering and simple calculations were the main factors for the higher viability score received in comparison to the rest of the indicators.

For the EoL indices (EoLi) (Favi et al., 2016), the viability (44%) is due to much of the required data being based on the economic values of material and energy, which increases the availability of the data.

### *Suitability of CE indicators*

The top five suitable CE indicators (Table 2) were selected for a deeper analysis:

- EoL indices (EoLi) (Favi et al., 2016): suitability 22.4%. This indicator provides quantitative information to select the best design and waste management choices. The required data includes: material and energy quantity and economic costs for manufacturing, the percentage of the material which is reused, refurbished, recycled and incinerated as well as the economic costs of those processes and values of the recovered material an energy. It provides guidance of the economic value of the design and EoL management choices for the EV battery.

- Product Circularity Indicator (PCI) (Bracquené et al., 2020): 21.5% suitability. The PCI is a single number indicator calculated based on the detailed assessment of the material efficiency for every process of the product, from the origin of the raw material, the manufacturing efficiency, the longevity of the battery, reuse/refurbishing of the components and recycling efficiencies. Thus, it was considered the most important CE indicator (68%) for the stakeholders, although viability was not as high (38%) due to the detailed data requirements.

- Circularity Index (CI) (Cullen, 2017): 20.4% suitability. The CI is an indicator focused on the recycling efficiency of the battery and the energy costs of the recycled material compared to the virgin raw material necessary to manufacture. As such, it is easy to calculate (48%) while providing simple yet interesting data (51%) regarding the recycling of the battery materials.

- Circular Product Index (CPI) (Saidani et al., 2019): 20.0% suitability. CPI is a questionnaire based semi-quantitative indicator that provides information on the circularity of the battery and its value chain by integrating technical data as the materials and weight of the product, second life and recycling ratios with qualitative data such as business practices, market analysis or economic and legislative conditions for the product. Thus, the stakeholders considered that the information provided was quite important (67%) but the low viability (36%) was based on the difficulty for the data gathering.

- Circular Economy Index (CEI) (Di Maio & Rem, 2015): 19.3% suitability. The CEI was deemed the most viable indicator (52%) by the stakeholders. It proposes a circularity score comparing the economic value of the recycled material vs. the virgin raw material, which was considered a medium importance (44%) information.

Other CE indicators, including The Circular Economy Performance Indicator (CPI) (Huysman et al., 2017) or the Circular Footprint Formula (PEFCR) (European Commission, 2018), were considered important (54% and 61%) but too complex (26% and 28%) due to requiring environmental impact calculations. Others such as the Global Resource Indicator (GRI) for life cycle impact assessment (Adibi et al., 2017), provided less important information (39%) while not being viable (32%) to calculate due to the inclusion of environmental impact and geopolitical scarcity of materials as data requirements for calculation.

## Conclusions

This paper outlines the opinion of 10 industrial stakeholders on the use of CE indicators to support decision-making processes for the circular design and sustainability management of EV batteries.

The evaluation of the importance and viability of 15 product-level CE indicators yielded interesting results regarding the suitability of the selected indicators to drive circular and sustainable innovation.

The two most suitable indicators, the EoL indices (EoLi) (Favi et al., 2016) and the PCI (Bracquené et al., 2020) are considered to provide detailed and complete information (Table 1, Table 2). Likewise, other CE indicators (CI (Cullen, 2017) and CEI (Di Maio & Rem, 2015)) scored high because of the ease of the data gathering and calculation, even if their scope was narrower (Table 1).

Besides, it can be observed in Table 1 that most of the assessed CE indicators lack the holistic approach necessary to analyse the complete lifetime of EV batteries. Thus, the definition of sector-specific CE indicators considering the design and development of EV batteries, adding life cycle perspective and an assessment of battery supply chain and business model’s configuration is an important step to focus on for further research on the topic.

# Digital technologies for a circular economy: Mapping sectoral applications and their environmental, social and economic impact

**Laura Piscicelli**[(a)]
a) Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, The Netherlands

**Keywords**: Circular Economy; Digital Technologies; Sectors; Impact; Sustainability.

**Abstract**: Policy makers and academics contend that digital technologies such as the Internet of Things (IoT), Artificial Intelligence and blockchain can enable and accelerate the transition to a circular economy. Despite a growing body of literature explores the implementation of a digital circular economy, insights are often limited to the manufacturing sector. Moreover, there is still little knowledge on the environmental, social and economic effects produced by a digitally-enabled circular economy. This paper presents the findings of a systematic literature review conducted to investigate the application of digital technologies for a circular economy and their sustainability impact across different industrial sectors. The IoT and advanced data analytics are the most common digital technologies in all sectors, except for accommodation and administrative/support service activities where online platforms are predominant. Blockchain and additive manufacturing/3D printing are most often discussed in the context of manufacturing, transportation, construction and waste management. The analysis also shows that the majority of articles describe potential positive environmental effects, but lack empirical evidence to uphold the often-stated sustainability promises of a digital circular economy.

## Introduction

Successfully aligning the green and digital 'twin' transitions is a priority policy objective of the European Union to deliver a sustainable, fair and competitive future (Mouthaan et al., 2023; Muench et al., 2022). Digital technologies, like the Internet of Things (IoT), artificial intelligence (AI), big data and blockchain, can help companies create economic value while minimising their negative social and environmental impact by narrowing, slowing and closing resource flows in the value chain (Chauhan et al., 2022; Hedberg and Šipka, 2021; Ranta et al., 2021). A growing body of academic literature is thus investigating how digital technologies facilitate the implementation of circular economy strategies and business models (Bressanelli et al., 2022; Cagno et al., 2021; Rosa et al., 2020), especially in the manufacturing sector (Antikainen et al., 2018; Ranta et al., 2021). These studies often highlight potential benefits for individual (frontrunner) firms (Schöggl et al., 2022), but fail to provide a comprehensive analysis of the environmental, social and economic effects of a digitally-enabled circular economy (Piscicelli, 2023). This significantly limits our understanding of the positive *vs* negative sustainability impacts of a digital circular economy, and leaves possible sectoral differences virtually unexplored. To address this knowledge gap, this paper investigates how the environmental, social and economic effects of a digital circular economy vary across industrial sectors.

## Methodology

The study is based on a systematic literature review of scholarly literature (peer-reviewed articles and reviews) written in English, published between January 2019 and June 2022, and indexed in the Scopus database. In the keyword-based search (TITLE-ABS) the term 'circular economy' was used in combination with terms related to impact (impact, effect) and a broad set of digital technologies (digit*, smart, IoT, big data, artificial intelligence, machine learning, additive manufacturing, 3D printing, blockchain, platform, augmented reality, virtual reality). The search string generated 278 documents, whose titles and abstracts were screened for eligibility.

Records that fell outside the scope of the study (e.g. papers only indirectly related to the topic of circular economy, or using the terms impact/effect for different purposes) or whose full text could not be retrieved were excluded. Of the 75 papers retained for the full-text review, 45 were finally included in the review and classified based on their general information (author(s), year of publication, journal, document type), content (circular economy strategy, digital technology, impact category and type, type of study, empirical methodology) and context (geographical scope, sector). Sectors were classified based on the 'International Standard Industrial Classification of All Economic Activities' (ISIC) developed by the Department of Economic and Social Affairs of the United Nations Secretariat (United Nations, 2008).

## Results and discussion

The analysis suggests that research on the environmental, social and economic impacts of a digital circular economy is still limited, albeit increasing over the years: more than 70% of the papers reviewed were published in the past two years. The majority of articles address only one digital technology (42%), or a combination of two (27%) or three (18%) digital technologies. Most papers focus on the IoT, followed by big data and advanced analytics (AI and machine learning techniques), blockchain, additive manufacturing/3D printing, and online platforms.

The results show that about half of the publications describe some form of sustainability impact resulting from a digitally-enabled circular economy in the manufacturing sector (with applications *i.a.* in the areas of food, textiles, machinery, motor vehicles, electrical and electronic equipment), waste management (11%), administrative and support service activities (4%) and construction (4%). Other sectors covered in the literature include financial activities, wholesale and retail trade, transportation and storage, accommodation and professional activities (11%). The remaining papers do not specify (4%) or combine multiple sectors (18%).

The IoT and advanced data analytics are the most applied digital technologies across sectors, except for accommodation and administrative/support service activities where online platforms are mentioned more frequently. These online platforms typically facilitate peer-to-peer (P2P) rental services (or 'sharing') of different product categories, e.g. homes (Cerreta et al., 2020), bicycles (Sun, 2021) and boats (Warmington-Lundström and Laurenti, 2020). This cluster of articles displays other important similarities: they often discuss social impacts (e.g. resulting from the excessive growth of tourism; the donation of remanufactured or refurbished bicycles to poor regions or not-for-profit organisations); they tend to focus on negative impacts, including rebound effects (i.e. the reduction in expected environmental or social gains from new technologies that increase the efficiency of resource use, due to behavioural or other systemic responses); and attempt to quantify the magnitude of impacts in empirical studies.
In contrast, the vast majority of papers included in the analysis only report on expected sustainability impacts; remarkably, just 10 out of 45 articles empirically measure environmental, social and/or economic effects, or cite evidence (e.g. numerical figures) from other studies. Environmental benefits are the most frequently identified (mentioned by 96% of the articles), followed by economic (64%) and social (60%) impacts. Most of the sustainability impacts discussed in the literature are positive (65%), whereas about a third of effects was coded as negative.

The second cluster of articles includes studies examining the application of the IoT and big data and advanced analytics in manufacturing, waste management, transportation, retail, financial, and professional/technical activities. In these sectors, the IoT can provide real-time data about an item's location and condition, thus supporting the design of products that can be easily maintained and upgraded, thereby extending product lifetimes (Atif et al., 2021; Fraga-Lamas et al., 2021; Magrini et al., 2021). During the manufacturing process, the IoT can also reduce material inputs and waste, reduce transportation emissions, close material loops and maximise resource efficiency (Atif et al., 2021; Khan et al., 2022). Big data and advanced analytics can serve as a tool to predict product health and wear, minimise resource use and optimise energy consumption from manufacturing to the end of the product lifecycle (de Souza et al., 2021; Magrini et al., 2021). As a results, they can reduce waste disposal and emissions, and avoid both environmental and financial losses (de Souza et al., 2021; Khan et al., 2022). Nevertheless, some authors mention the need to assess potential risks and the environmental burden caused by the widespread implementation and disposal of IoT devices, e.g. sensors, gateways and asset trackers (Atif et al., 2021; Condemi et al., 2019), and the large amount of energy needed for computing and data centres (Fraga-Lamas et al., 2021; Hoosain et al., 2020). Concerning social impact, the IoT is reported to facilitate stakeholder involvement in supply chains, but the promises of bringing net gains to society in terms of employment opportunities (Maiurova et al., 2022), improved working conditions, and social equity need to be further explored (Rejeb et al., 2022). With regard to economic impact, the application of the IoT is believed to reduce costs and improve firms' financial performances (Atif et al., 2021; Bressanelli et al., 2022; Magrini et al., 2021).

Manufacturing is the sector where the blockchain technology is most frequently discussed, with some applications in the context of reverse logistics (Alves et al., 2022; Krstić et al., 2022) and waste management (Ajwani-Ramchandani et al., 2021). In this third cluster of articles, blockchain is reported to improve supply chains traceability and transparency, e.g. it helps monitoring and proving to the customers the (environmental and social) sustainability of the products manufactured, while increasing the financial performances of the firm (Upadhyay et al., 2021). Blockchain can also be used to engage consumers in circular economy processes (Alves et al., 2022), and is considered particularly promising in developing economies where formal institutions are often underdeveloped and bring low trust to market transactions (Ajwani-Ramchandani et al., 2021). High energy costs required to power the blockchain, initial technology investment and infrastructure setup costs, and a lack of immediate financial rewards (Ajwani-Ramchandani et al., 2021; Magrini et al., 2021; Upadhyay et al., 2021) are often mentioned as challenges for the implementation of blockchain for a circular economy, although most authors argue that the realisable benefits largely outweigh the downsides (Ajwani-Ramchandani et al., 2021; Upadhyay et al., 2021).

In the last cluster of articles, additive manufacturing and 3D printing techniques are mainly related to manufacturing, with some applications in the areas of transportation and construction. These digital technologies have the potential to reduce/minimise the consumption of raw materials, energy and waste (de Mattos Nascimento et al., 2022; Laskurain-Iturbe et al., 2021; Mattos Nascimento et al., 2019; Monteiro et al., 2022). They make it possible to manufacture an asset close to where it is needed, possibly using local and/or recycled materials as feedstock, thereby reducing the environmental load of production operations (e.g. material losses and waste, reducing transport and greenhouse gas emissions) (Bressanelli et al., 2022; de Mattos Nascimento et al., 2022; Laskurain-Iturbe et al., 2021; Vaccaro and Buoninconti, 2021) and creating economic benefits for firms (de Mattos Nascimento et al., 2022). From a social perspective, additive manufacturing and the so called 'maker movement' are believed to spawn new skills and jobs, support community cohesion and promote personal satisfaction (Mattos Nascimento et al., 2019). Still, some authors report that 3D printing can increase resource consumption as a result of increased demand for customised goods and a higher rate of product obsolescence (Di Maria et al., 2022).

## Conclusions

Policy makers and academics are increasingly framing digital technologies as key enablers for the transition to a circular economy. This review provides novel insights into their application across a variety of sectors and shows that while some digital technologies are highly versatile and can be adopted for different purposes in different industries (e.g. the IoT and advanced data analytics), others show only limited applicability beyond the scope of specific use cases and sectors. Similarly, some digital technologies appear to cause more (collateral) negative effects than others (e.g. P2P platforms *vs* additive manufacturing/3D printing). When discussing the role of digital technologies in facilitating circular products and business models, it is thus important to discriminate among digital technologies: some are likely to play a larger role, whereas others just a marginal one; and some will deliver more beneficial (or negative) effects than others.

Nevertheless, the limited number of articles included in this review demonstrates that research on digital technologies in the context of a circular economy is still in its infancy: while there is a growing interest in the digital circular economy, not many academic papers acknowledge its environmental, social and economic impacts, and only few studies do so empirically. Given that some sectors are discussed in only one or two articles (e.g. retail trade, construction, accommodation, professional and financial activities), it is difficult to draw generalisable conclusions on sectoral differences. Yet, research that systematically measures and assesses the sustainability impacts of a digitally-enabled circular economy is much needed if we chorally promote and hope to reap the benefits of a twin transition.

# Is second-hand clothing all the same? Understanding swapping events in relation to charity retail in the UK

**Lucie Pocinkova**
School of Design, University of Leeds, Leeds, UK

**Keywords**: Swapping; Charity retail; Clothing; Collaborative consumption.

**Abstract**: This paper aims to explore the role of swapping in relation to charity retail stores in the UK. The paper investigates swap organizers and consumers, to understand the role swapping events in the wider context of second-hand clothing consumption and outlining the previously unexplored links between charity stores and swapping events. Swapping events, similarly to charity retail, play a significant part in extending clothing use through recirculation between multiple users. Notwithstanding, this paper discusses the tension which arises as a result of diverging objectives of charity retail and swapping and its impact on consumer participation in swapping and growth of the niche practice, intended sustainability-related benefits as well as supply chain implications for the second-hand clothing realm. This qualitative inquiry is based on 29 in-depth interviews with consumers who attend swapping events as well as organizers of swapping events in the UK. Data were analyzed using a 7-step approach to data analysis. The findings show that the different objectives of charity versus swapping events influence consumer participation in swapping and can also cause misunderstanding of the role of swapping events. Findings further show the misalignment between consumer and organizer expectation of swapping events, where some consumers perceive charity retail and swapping to be synonymous. This paper further points to supply chain management of used clothing and the related sustainability implications of un-swapped clothing. This paper extends the understanding of swapping events in relation to charity retail which has important implications for the growth of the swapping practice. The paper makes recommendations relevant for marketing, policy and practitioners to better align the activities as well as differentiate charity retail and swapping, benefiting each mode respectively.

## Introduction

Excessive over-consumption of clothing continues to outpace the utilization and garments are being wasted through idle capacity or premature disposal (Coscieme et al., 2022; Vladimirova et al., 2022). Swapping is a form of collaborative fashion consumption and has emerged as a potential solution to the growing issue of clothing underutilization and waste (Henninger et al., 2019). Although swapping is currently niche, it serves an important purpose of extending garments' lifetime through increased recirculation among multiple users (Rathinamoorthy, 2019).

Swapping lies at the intersection of second-hand clothing, collaborative fashion consumption and charity retail (Ertz et al., 2016; Hur, 2020). The term 'second-hand' envelops both swapping and charity retail, with clear definitions of each model outlined in literature (e.g. Osterley & Williams, 2018; Henninger et al., 2019), however the relationship between the two modes presents a gap in current understanding of the second-hand clothing market (Pal et al., 2019; Brydges, 2021), which the current research aims to fill through questioning the nature of swapping events in comparison to charity retail. Although both models play a significant part in redistributing second-hand clothing, there can be a diverging set of objectives governing their purpose and role in the wider context of circular economy, which can impact consumer participation (Albinsson & Perera, 2012; Camacho-Otero et al., 2019). As such, this paper aims to explore how swapping consumers and organizers perceive the role of swapping events and their function as part of the second-hand clothing realm. Where previous research has investigated clothes swapping through intentions and motivations (e.g. Armstrong et al., 2015; Lang & Armstrong, 2018a, 2018b; Lang & Zhang, 2019), engagement and development (e.g. Matthews & Hodges, 2016; Philip et al., 2019; Camacho-Otero et al., 2019), typology (e.g. Rathinamoorthy, 2019) and supply chain implications (e.g. Henninger et al., 2019), this paper questions the nature of swapping events as social enterprises through charity retail comparison. This research is significant as it provides deeper insight into swapping as part of the circular fashion system, representing an important puzzle piece in the labyrinth of transitioning to greater fashion sustainability. In addition, the paper contributes to better understanding of swapping supply chain implications in relation to charity retail and collaboration across industry initiatives and actors.

## Literature review

### *Clothes swapping in the circular fashion economy*

Swapping refers to the exchange of garments, whereby ownership is redistributed between individuals, without monetary fees (Henninger et al., 2019; Philip et al., 2019). As alluded to, swapping is part of the collaborative fashion consumption phenomenon and, at the same time, rests beneath the circular economy in fashion umbrella, as a way to promote recirculation and utilization of garments among consumers (Henninger et al., 2021). Whilst swapping is considered a niche practice, the events themselves play a significant part in advancing circular fashion transitions on a local level (Pal & Gander, 2018; Elf et al., 2022).

Swapping events can be classified as community-based enterprises as they primarily serve the surrounding community with an opportunity to partake in an alternative consumption mode for clothing acquisition and at the same time divert clothing from landfill (Sforzi & Bianci, 2020). Previous research found consumers participating in swapping due to environmental, social and economic benefits of the practice (Camacho-Otero et al., 2019) as well as hedonic values such as finding unique clothing pieces (Lang & Armstrong, 2018b; Lang & Zhang, 2019). In majority, swapping events are ran by volunteers and nonprofit organizations (Henninger et al., 2019). Rathinamoorthy (2019) further points to clothing swaps being organized to fundraise for a particular charity, blurring the classification of these enterprises.

The format of in-person swapping events can either be mediated by an organizer, formally facilitating the exchange of garments, or in the form of private swap parties that tend to happen between family and friends (Ertz et al., 2016; Rathinamoorthy, 2019). During swapping, consumers adopt a dual role of 'providers' and 'obtainers', which means that to obtain clothing, consumers must first let go of owned clothing in order to participate (Ertz et al., 2016). Consumers can therefore be simultaneous suppliers which presents supply chain implications such as uncertainty for organizers as well as second-hand clothing market (Henninger et al., 2019). Clothing items which are not swapped are either 'recycled' or donated to charity (Henninger et al., 2019; Camacho-Otero et al., 2019) which invites the following research question addressed in this paper: what are the supply chain implications for clothes swapping events in relation to charity retail from the perspective of clothes swap organizers and consumers?

### *Charity retail*

Charity shops have a longstanding history in the UK and are particularly popular as destinations for unwanted garments (Parsons, 2004; WRAP, 2019). Charity retail serves multitude of purposes such as a recycling hub for unwanted items, fundraising venture for particular a charity or cause, a community nexus as well as opportunity for volunteering and employment (Pue, 2019). Moreover, charity shops provide consumers with economically accessible second-hand fashion items (Du et al., 2010). The above purposes coincide with clothes swapping events, yet their relationship remains unexplored in literature. Although charity shops have been previously praised for their social and environmental benefits (e.g. Harrison-Evans, 2017), emerging evidence from developing countries shows the devasting impacts of second-hand clothing trade in the form of growing waste mountains (Manieson & Fererro-Regis, 2022). This is particularly relevant for the UK where 60% of donated clothing is exported overseas, making clothing donations problematic (WRAP, 2019).

Similarly to swapping events, charity shops play an important role in redistributing existing clothing and supporting reuse, therefore being part of the circular economy in fashion

(Farahani et al., 2021). Besides economic reasons, the association and direct support of the parent charity tends to be the leading driver for shopping in charity shops (Harrison-Evans, 2017) which can also be the case for clothes swapping events (Rathinamoorthy, 2019)

Given the common characteristics of charity shops and swapping events, this paper poses the following research question: *what is the role of swapping events in comparison to charity retail as perceived by swapping consumers and organizers?*

## Methodology

This qualitative enquiry uses 29 semi-structured interviews conducted with organizers (11) of clothes swapping events as well as consumers (18) that have experience with swapping. Organizers were selected using purposive sampling and shared a common characteristic of coordinating a minimum of five publicly advertised swapping events in the UK. Organizers were found through social media and search engine and were evenly distributed across the UK. Consumers were selected using purposive and snowball sampling with a key criterion of 'experience with attending at least one swapping event in the UK' (Ritchie et al., 2014). Another necessary attribute for research participation was that attended and coordinated swap events were publicly accessible, meaning swapping occurred between strangers as opposed to a closed circled of family and friends (i.e. swap parties) which were previously investigated (Matthews & Hodges, 2016).

The interviews embraced a semi-structured format which combined flexible and open-ended style of questioning based on an interview guide (Rubin & Rubin, 2012). The researcher posed probing questions when appropriate to draw out participants' experiences. The interviews were centered around the topic of swapping enquiring about either swapping organization (organizers) or experience (consumers). The researcher followed up with questions surrounding the role of swapping events and how would participants define these (e.g. business, social enterprise, charity/not-for-profit). The interviews were conducted online using Zoom, recorded and transcribed verbatim.

Data were analyzed using Easterby-Smith et al.'s (2018) seven step guide to data analysis (familiarization, reflection, open coding, conceptualization, focused recoding, linking and re-evaluation) which allows for themes to emerge and multiple rounds of iterative scrutiny. Data were coded using NVivo. Data collection was completed when data reached a theoretical saturation point, or additional new information and coding was not feasible (Charmaz, 2014). The data analysis approach followed a precedent in the swapping context (e.g. Henninger et al., 2019).

## Findings & Discussion

### *Consumer misunderstanding of differences between modes*

A reoccurring theme found within the dataset is the misunderstanding of the differences between charity shops and clothing swaps. Whilst research participants note that swap events are different in that they require clothing to be brought in, they have also stated that some of them do the same in charity shops and donate clothing regularly [C01; C10; C13]. Another key difference identified by consumers was the one-off fee paid to access the event as opposed paying for each garment individually as they would in a charity shop. While this was true for the majority of the interviewed organizers as well, one particular swap shop had a unique model of selling items individually [O02]. The number of items people could 'swap out' was based on the number of items brought, but instead of a flat fee, each item was paid for upon check out [O02]. According to the organizer, this alleviated the pressure to consume unnecessary items and only pay for those that consumers truly wanted, which reflects the pricing architecture of a charity retail store. As such, this type of 'swap shops' can contribute towards consumer confusion regarding the difference between swapping events and charity retail.

Consumers further referred to clothing swaps and charity retail interchangeably during the interview, often using both words at the same time such as "charity or swaps" when asked about either of the two. This lack of differentiation can be partially explained by the similar type of stock that charity shops and swap shops carry, as explained by a swap attendee: "I don't really consider there to be a difference between charity shops or second hand, oh wait sorry I meant swap shops, especially when it comes to clothes. Its all very similar" [C06]. This was further corroborated by some of the swap organisers which reflected on the quality of their apparel as that similar to charity retail, despite having attempted to be more selective of clothing items during check in process [O07; O09].

Another aspect that could be considered as contributing to the confusion of consumers and misunderstanding of swaps is the type of benefit provided by swaps and charities: "To me it isn't that much different really, charity or swaps are both good for used stuff to go around and at least it doesn't end up in the bin" [C15]. Clothing swaps were thus perceived to be identical in that they prevent clothing from being disposed of in household bins and they are being reused. An important additional factor complicating consumer understanding could be that some clothing swaps are organized as charity fundraisers. This means that clothes swap organizers are donating all proceeds to a chosen charity [O01; O03; O04; O05]. As a result of some swaps being charitable events and others not, this research suggests the role of swapping events within the fashion system is unclear to consumers, which can influence uptake of the practice and its growth.

### *Supply chain implications of un-swapped clothing*

From the comparative exploration of clothes swapping events and charity retail, a key finding emerged regarding the differences in handling 'left-over clothing' which has implication for second-hand clothing supply chain management. Previous research found un-swapped clothing from swapping events is donated to charity shops (e.g. Henninger et al., 2019), which was confirmed by organizers in this research study. This means that clothing swaps are actively contributing to the supply of second-hand clothing and donated items are likely to be recirculated again. Nonetheless, this poses issues if, as previously mentioned, clothing does not get resold in local or national markets but instead is shipped overseas (Guo et al., 2021). Stock rotation is a common practice in charity retail with unsold merchandise being rotated along a network of charities after not being sold for a certain period of time (Burnett, 2022). The same cannot be said for clothes swapping events as they are in majority not part of an interconnected network of organizers and are, therefore, at a disadvantage, having to resort to donating leftover stock to charity shops as opposed to other organizers. One organizer highlighted giving stock to another swap event if the clothing remained un-swapped for several weeks [O02]. This was however an isolated incident among other interviewed organizers. Thus, one of the key recommendations of this research is that a network of clothes swapping events is established to support recirculation of clothing among events and thereby minimize supplying to charity shops.

## Conclusions

Whilst both swapping events and charity shops are ultimately similar in that they redistribute second-hand clothing, the differences between each mode are often not clear to swapping attendees. This can be explained by the similar merchandise in both swaps and charities and coinciding environmental and social objectives such as preventing clothing from landfill as well as fundraising for specific charities. Moreover, this research found that swapping events lack a network of organizers which would aid with recirculation of un-swapped apparel across different events and thereby impacting the supply chain of second-hand clothing.

In order for the practice of clothes swapping to shift from its current niche status, greater uptake and consumer demand is necessary. However, without appropriate education and awareness of the nuances between other modes it will be difficult to achieve. This research has thus contributed to better understanding of clothes swapping events from the organizer and consumer perspective in relation to charity retail.

# Towards Durability and Extended Lifespan – Caring for Clothes as a Sustainability Practice

**Janne Poikolainen[a], Sanna Sekki[a], Minna Autio[a,b], Henna Kettunen[a], Riikka Räisänen[a,b]**

b) Helsinki Institute of Sustainability Science HELSUS, University of Helsinki. Finland

**Keywords**: Consumer; Clothing; Care; Sustainability; Materiality.

**Abstract**: Care is an increasingly important perspective in studying and defining potential paths towards more sustainable lifestyles and consumer practices. In this qualitative study, we examine Finnish consumers' perceptions and practices of product care in the context of clothing consumption. The data of the study consists of 27 thematic interviews. Our findings indicate that when considering the purchase of a new garment, consumers are already weighing the maintenance properties of the clothes as well as their own personal willingness to commit to taking care of the product. Consumers expect pricy and branded clothes to be of high quality, and show more interest in taking care of them than in maintaining more mundane and low-cost garments. Consumers also favour natural materials, such as cotton, silk, and wool, due to their durability and ease of maintenance. During the use phase, appreciated clothes are maintained through care practices such as washing (or refraining from washing), ironing, and mending. Through these practices, consumers extend the lifespan of their clothing, thus increasing the sustainability of their consumption habits. In conclusion, our study emphasizes the role of a meaningful product relationship – based on either the economic, cultural, or personal value of the garment – as an important motivator for product care and, consequently, more sustainable clothing consumption.

## Introduction

Textile production is the world's second-most polluting branch of industry, topped only by the oil industry (Chen et al., 2021). It has been estimated that the production and consumption of textiles will triple by 2050 (Sitra, 2022), which is likely to drastically exacerbate the environmental burden caused by the textile industry. All stakeholders (e.g., industry, policymakers, consumers) are obliged to address this environmental threat. For consumers, this means transforming the consumption of textiles and clothes towards a more sustainable path (e.g., Rausch & Kopplin, 2021). The current culture of overconsumption is characterized by the presence of cheap, low-quality, and unsustainable fast fashion products (Ahmed, 2021). Niinimäki et al. (2020) argue that the low cost of clothing reinforces the phenomenon of buying more items and wearing them less frequently. Producing and consuming fast fashion garments contributes to our waste-generating "throwaway society" (Cooper, 2005) and promotes the short-term use of consumer goods.

From the point of view of sustainability, care is becoming an increasingly important concept. In fact, in today's consumer culture, calls for caring are everywhere: companies compete with green products to show how much they care, while consumers adopt more sustainable consumption habits to show that they care, too (Puig de la Bellacasa, 2017). Within the discussion of (un)sustainable consumption, caring has often been associated with a commitment to ecological and ethical responsibility (Godin, 2022). On the level of consumers' relationships with commodities, care can also be approached from a more practical perspective of product care (e.g., Ahmed, 2021). Product care aims at increasing the durability of products through maintenance and repair, thus forming an important cultural link towards more sustainable consumption (Harper, 2018).

Prior scholarly interest in the sustainability of clothing consumption has primarily focused on purchasing behaviour, anti-consumption, and practices related to the disposal of textiles (Jung & Jin, 2016; Niinimäki et al., 2020; Paco et al., 2021; Vesterinen & Syrjälä, 2022).

However, in this paper, we apply the care perspective as an approach to the sustainability aspects of consumer use and treatment of clothing. In particular, we study how consumers reflect, perceive, and execute caring practices in the contexts of purchasing and maintaining garments, and how their commitment (or noncommitment) to caring is constructed. In other words, we approach (product) care as both the consumers' caring activities and their overall relationships with clothing (see Puig de la Bellacasa, 2017).

## Care, Clothes and Sustainability

In the field of consumer studies, consumption has been connected to caring in multiple ways (Godin, 2022). First, the concept of care has gained a foothold in the context of familial consumption. Miller (2005) suggests that shopping is often an act of familial love and care, and the practices of taking care of family members via the consumption of commodities (e.g., food, clothes, household items) are considered "emotional labour" (Godin, 2022). Second, the link between consumption and care has been discussed in the context of sustainability. As Godin (2022) suggests, from this perspective, forms of ethical and ecological consumption can be interpreted as caring for "distant others" and the world around us. Consequently, care practices have been brought up as a useful lens for studying the (un)sustainability of our daily consumer activities.

From the standpoint of sustainability, care can also be understood in the sense of product care, that is, in the concrete work of maintenance (e.g., Ahmed, 2021; Puig de la Bellacasa, 2017). Product care, in the context of taking care of and repairing purchased items, forms an important role in the transition towards a more sustainable consumer culture, as it contributes to increasing the durability and lifespan of products (Harper, 2018). Vesterinen and Syrjälä (2022) argue that prolonging the use of clothing is crucial when promoting the sustainable consumption of textiles. In the context of clothing, product care is also linked to the price and perceived quality of the product. McNeill et al. (2020a) suggest that when consumers consider a garment to be of high quality (based on brand and price; see also Connor-Crabb & Rigby, 2019), they are more willing to extend its lifespan by taking care of it. Similar findings were made by McNeill et al. (2020b) in their more recent research on the interests of fashion-oriented consumers in maintaining fashionable clothing.

Even though product care forms an important aspect of more sustainable textile consumption, our current practices of textile care are not free from sustainability challenges. For example, people typically consume a lot of water and energy when washing, drying, and pressing clothes (Ahmed, 2021). In this sense, it is not enough that we take care of our clothes; we should also rethink how this caring is done. Addressing these challenges, Godin et al. (2020) studied how consumers could reduce the frequency of laundering to increase the sustainability of their maintenance practices. During the study, consumers made changes in their laundering habits, such as reducing laundry cycles, airing out clothes, or removing stains by hand instead of washing the whole garment. As a result, the participants learned to better assess the need for washing and to find alternatives without compromising cleanliness (Godin et al., 2020).

## Data and Methods

Our study was based on thematic interviews of 27 Finnish consumers, aged 24–73 years. Seven of the participants were men and twenty were women. The interviews were conducted in 2020–2021, and the interviewees participated in them either individually or in groups of 2–3 people. The interviews lasted 30–80 minutes and were recorded and transcribed. The interviewees were recruited using the snowball method (Geddes et al., 2018), in which researchers and/or research participants utilized and activated their own social networks (Noy, 2008) for the purposes of participant recruitment. During recruitment, participants were informed about the purpose of the study and the overall progress of the research process. The interviews were guided by a thematic structure (Krueger & Casey, 2014), covering various themes of consumer–garment interaction, from the acquisition of clothing to maintenance practices and, eventually, recycling/disposal. Sustainable clothing consumption and the aesthetics of garments (e.g., colours) were also discussed. The interview data were analysed qualitatively, with a special focus on product care practices and consumers' (non)commitment to caring.

## Caring Begins: Negotiating the Level of Commitment During Acquisition

Although the use phase is the main venue of clothing care, the perspective of product care often enters the process of consumption when consumers are about to purchase the garment. During the acquisition, consumers evaluate the materials used in the clothing, and often reflect on the material and the amount of care it requires. However, the level – and the overall existence – of such reflection clearly depends on the characteristics of the product, and the personal meanings attached to it. As the following citation from one interview indicates, the purchase of low-cost and mundane clothing, such as ordinary T-shirts or socks, may not necessarily involve any deep interest in the garment's material and maintenance properties. Instead, the only thing that the interviewee pictured as worth checking in such a case was that the shirt was made of cotton, a fabric pleasing to her. With socks, the interviewee's interest in the material and maintenance features was rather indifferent. However, when it came to more expensive and exquisite clothes, she was clearly more motivated to take these aspects into account:

> If I buy a t-shirt from Lidl with ten euros, I just check that it's cotton, and that's it. No need to read [the tags] more carefully. However, if I buy an expensive down jacket or winter jacket, I will check not only the material properties but also if it can be washed, and how it behaves. But with, like, cheap socks, I hardly look [at the info tags]. (Consumer 6, female, 53 years)

The quote suggests that the act of purchase can be seen – at least to some degree – as a process of negotiating the level of future commitment to the garment. Moreover, this level seems to be connected to the price of the product, with consumers showing a greater aspiration to create caring longer-term relationships with expensive clothes. This mindset also became evident in relation to high-level brand products. In the following example, interviewee weighs the distinction between the clothes of the fast fashion store H&M and the Finnish brand store Marimekko:

> Somehow, people treat brand clothes better. A Marimekko shirt is valued higher than an H&M shirt. … Yes, you somehow think that you need to treat it more accurately and carefully to maintain the garment. More than the cheaper one. (Consumer 12, female, 25 years)

When purchasing more expensive (brand) clothes, consumers pay more attention to the durability of the materials and the maintenance properties of the garments. The interviewees expressed that they favour natural materials like cotton, silk, wool, and leather, as these materials are considered durable and easy to maintain (e.g., to wash or iron). They rely on familiar materials, trusting that the garment will meet their expectations. In the same way, the interviewees accepted that low-cost materials would not necessarily last in use.

Overall, choosing pricy brand products is seen as an investment in the extended lifespan of the garment, both in the sense of paying extra for the (assumed) quality of materials and in the form of committing to cherish the durability of the product by investing personal time in its care. In fact, this investment often means prolonging the life of the garment, even beyond the sphere of personal use. As McNeill et al. (2020a) point out, purchasing brand products with higher prices spurs consumers to extend the lifespan of these clothes by, for example, selling or gifting the items after they have finished using them.

## Caring continues: Maintenance During the Use Phase

The practices of caring, aimed at prolonging the lifespan of the product, become concrete during the use phase of clothes. This was illustrated in multiple ways by the interviewees' descriptions of the maintenance practices they employed to increase the lifespans of garments. In their simplest forms, these included familiarizing themselves with and following the maintenance instructions for taking care of the cloth, particularly when dealing with less familiar fibres. A more thorough interest in product care (and related information) also takes place in the case of pricier brand clothes (see also McNeill et al., 2020a/b):

> If I have bit better shirts, like those Marimekko ones, I will surely check on what temperature they should be ironed with … But [in general] I rarely feel a need to check the ironing labels. (Consumer 22, female, 49 years)

The interview data also imply that consumers may reduce the frequency of certain maintenance practices to sustain the garment's appearance (and to decrease the environmental burden of caring). For example, the interviewees pointed out that they carefully assess the need to wash the garment because laundering may wear out the fabric. They also mentioned airing and stain removal as alternatives to washing.

In addition to careful washing and ironing, some interviewees referred to more advanced forms of product care, such as repairing clothes or reviving worn-out fabrics. In the following example, such reviving had resulted in an already worn garment regaining much of its earlier appearance:

> I got myself a battery-powered lint remover. It's quite handy, especially for knit garments and clothes that may become linty. Particularly, if they contain some synthetic fibre, they produce lint easily. ... It makes the garment look a bit like new again. (Consumer 2, female, 31 years)

In another case, a 57-year-old interviewee referred to a more old-fashioned (i.e., clearly predating the era of fast fashion) method of protecting the cloth from stains and reducing the need for washing, namely, underarm sweat pads. "[I was taught] that you must sew those pads onto the armpits of your blazer so that you can wash them when you sweat, and you don't have to wash the whole jacket." (Consumer 18, male, 57 years)

The data also contain several descriptions of repairing well-used products. Of these descriptions, the following is particularly thought-provoking: "For example, I mend my favourite socks, and I get sad every time a new hole appears" (Consumer 4, female, 67 years).

What makes this quote interesting is how it illustrates the meaning of the link between personal – in this case, clearly emotional – attachment to a garment and the interest in taking care of it. The quote supports the idea that committed, long-term caring often presupposes a certain level of personal appreciation and respect for the clothing. As has already been seen, such a positively meaningful relationship can be constructed on market-based features (e.g., a valued brand), but as the case of old socks suggests, this link can also be based on more personal meaning (e.g., the garment as a carrier of personally meaningful memories).

## Conclusions

The findings of this study suggest that the process of caring (or not caring) begins when consumers are about to purchase a garment. In this phase, consumers often evaluate the material and maintenance properties of the clothing, as well as their own willingness to engage in different forms and levels of caring. However, both the thoroughness of this reflection and the intended level of engagement seem to vary according to the value of the product. For example, consumers show higher interest in, and commitment to, maintenance and caring in relation to brand clothing, whereas the attitudes towards more mundane garments appeared as more careless and ignorant. This tendency became even more evident in the use phase, during which caring was (or was not) put into practice in the form of concrete maintenance and repair.

Overall, the study underlines the importance of a meaningful product relationship as a motivator for product care, as such a relationship, based on the economic, cultural, or personal values of the product, clearly promotes the purchaser's commitment to long-term product care. As product care typically aims to extend the lifespan of the garment, this meaningfulness also contributes directly to the sustainability of clothing consumption. Moreover, our findings imply that these kinds of appreciative relationships are much more unlikely in the context of fast fashion consumption, thus supporting the prior concern about the unsustainability of current fast fashion culture.

# Digital technologies for LCA – A review

**Martin Popowicz[(a)], Josef Peter Schöggl[(a)], Rupert J. Baumgartner[(a)]**
a) Christian-Doppler-Laboratory for Sustainable Product Management Enabling a Circular Economy, Institute of Environmental Systems Sciences
University of Graz, Merangasse 18/I, 8010, Graz, Austria

**Keywords**: Life cycle assessment; Artificial intelligence; Blockchain; Internet of things; Big data.

**Abstract**: To become more circular and sustainable, firms need to increase the understanding of environmental impacts of their products and services. For the assessment of environmental impacts, life cycle assessment (LCA) has become widespread. Although there have been ongoing improvements of the LCA methodology and data provision for LCA, still many challenges remain such as time-consuming data collection or life cycle inventory data gaps. Digital technologies can help to overcome challenges in LCA, thereby also making LCAs more accessible for practitioners and hence potentially increasing the durability of products and vice versa also the circularity and sustainability performance of companies. Therefore, it is important to identify how digital technologies can be used in the context of LCAs. In this contribution we show how digital technologies, namely blockchain, the internet of things (IoT), big data and artificial intelligence (AI) can be used within the LCA process. To identify how the different technologies contribute to LCAs, a systematic literature review of 38 peer-reviewed journal and conference articles was performed and the different contributions were attributed to the three LCA phases according to ISO 14040 and ISO 14044: goal and scope definition, inventory analysis and impact assessment. Our results show, that IoT is used in the inventory analysis phase, while blockchain, AI and big data have several applications in goal and scope definition, inventory analysis as well as impact assessment phase. The results reveal how digital technologies can be applied in LCA and how their application can facilitate the calculation of LCA results.

## Introduction and background

For creating more sustainable products, for instance by increasing product lifetimes, companies need to gain an understanding of environmental impacts of their products. To evaluate these impacts, life cycle assessment (LCA) has become a widespread tool. LCA consists of four distinct phases: goal and scope definition, inventory analysis, impact assessment and interpretation (ISO, 2006). The rising popularity of LCA can inter alia be attributed to the tool´s ability to serve as powerful support for decision makers (Curran, 2014) and according to Jolliet et al. (2015) LCA incorporates all environmental challenges known today. Although LCA is improved continuously several challenges still remain. One major challenge is data collection (Testa et al., 2016). It is estimated, that about 70% to 80% of time and costs for conducting an LCA are related to data collection in the inventory analysis phase (Miah et al., 2018). Also challenges regarding data inaccuracy and data gaps can occur during the data collection process (Bjrklund, 2002). Further the lack of data for life cycle impact assessment, meaning data that that links the emissions and extractions to the corresponding impact categories, constitutes a challenge (Curran, 2014). Reap et al. (2008b) especially point out to data gaps regarding the toxicity related impact categories. Furthermore, dealing with data uncertainty and the allocation of environmental burdens in the case of one process leading to multiple products are considered challenging (Curran, 2014; Reap et al., 2008a). Finally, LCA requires validation of the exchanged information for ensuring credibility (Teh et al., 2020). Especially when data is obtained from outside of the LCA conducting organization, it can be of unknown quality (Reap et al., 2008b).

Digitalization can help in overcoming several remaining challenges. Therefore, this paper focuses on the identification of applications of digital technologies for facilitating the conduction of LCAs. It focuses on those technologies which are regarded as especially important for achieving a more circular economy by the European Commission (2020): internet of things (IoT), big data, artificial intelligence (AI) and blockchain. IoT can basically be defined as: "Group of infrastructures interconnecting connected objects and allowing their management, data mining and the access to the data they generate." (Dorsemaine et al., 2015, p. 73). Big data is data, that can be characterized by three V´s: Volume, variety and velocity (Fasel & Meier, 2016). AI is defined by (Nilsson, 2009, p. XIII) as: "Artificial intelligence is that activity devoted to making machines intelligent, and intelligence is that quality that enables an entity to function appropriately and with foresight in its environment." Finally, blockchain is described by Crosby et al. (2016, p. 8) as follows: "A blockchain is essentially a distributed database of records, or public ledger of all transactions or digital events that have been executed and shared among participating parties. Each transaction in the public ledger is verified by consensus of a majority of the participants in the system. Once entered, information can never be erased."

The following research question is answered in this paper: How are IoT, big data, AI and blockchain applied within the LCA framework? The remainder of the paper is structured as follows: section 2 introduces the methodological approach, section 3 presents the results and section 4 provides the conclusions. It has to be remarked that there are already existing reviews focusing on one of the investigated technologies (Ghoroghi et al. (2022); Karaszewski et al. (2021)), but to the author´s knowledge, a review that includes all four investigated technologies is still lacking.

## Method

A systematic literature review was performed to answer the research question. The identified applications of digital technologies were attributed to the corresponding LCA phases according to ISO 14040/14044. The identification of relevant literature was carried out in several steps, pictured in detail in figure 1. The initial search terms leading to 270 results are shown in table 1. Further only journal articles and conference papers were included in the analysis.

| Technology | Search term |
|---|---|
| Internet of things | TITLE-ABS-KEY ("life cycle assessment" AND ("internet of things" OR "IoT")) |
| Blockchain | TITLE-ABS-KEY ("life cycle assessment" AND "blockchain") |
| Artificial intelligence | TITLE-ABS-KEY ("life cycle assessment" AND ("artificial intelligence" OR "machine learning")) |
| Big data | TITLE-ABS-KEY ("life cycle assessment" AND "big data") |

**Table 1. Initial search terms.**

The search was carried out in April 2022 and SCOPUS was selected as search database. As inclusion criteria especially the application of one of the selected technologies within the ISO framework for LCA was seen as relevant. For the in-depth analysis of the 38 papers the software package MAXQDA was used.

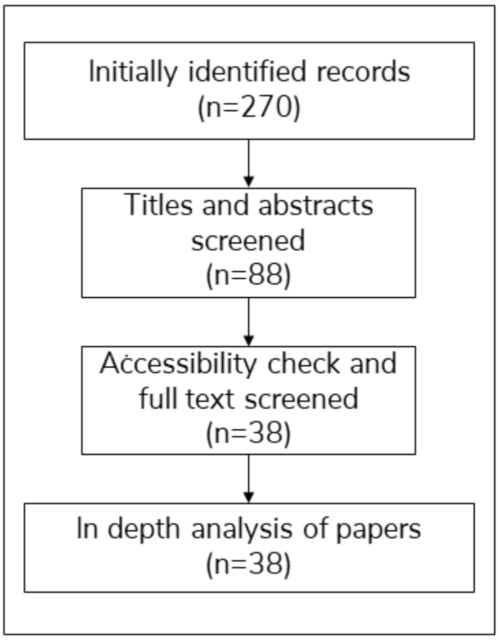

**Figure 1. Research process.**

## Results

### *LCA and IoT*

IoT technologies are used within the inventory analysis phase according to ISO 14040/14044 for data collection. Figure 2 summarizes the applications of IoT for LCA.

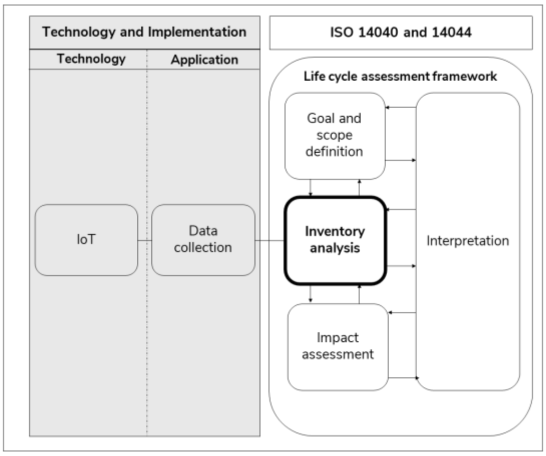

**Figure 2. LCA and IoT.**
Source: based on ISO (2006)

Garcia-Muiña et al. (2018) suggest that IoT technologies can be used for the collection of process data to build databases for LCAs. They store the manufacturing data collected via sensors in the company's ERP which then serves as suitable database for LCAs. While Garcia-Muiña et al. (2018) manage data collection via IoT in a centralized way van Capelleveen et al. (2018) choose a decentralized way. They propose that the data are stored directly on components and suggest a hybrid system consisting of the decentralized sensors and storage nodes paired with a centralized data respiratory to enable LCA calculation. Mishra and Singh (2019) use LCA for the tracking of carbon emission along the product development life cycle and use IoT technologies to collect real time data of the emissions generated by the product. According to Ingrao et al. (2021) the use of IoT can offer the advantage of more specific data for LCAs. They use sensors to measure the electric consumption of machines, calculate an LCA and compare the corresponding results with the outcomes of two more generic models. Tao et al. (2014) suggest an LCA calculation based on the BOM of products and IoT technologies. They use IoT for the perception and collection of energy consumption and environmental impact data regarding the whole life cycle of a product and introduce the so-called big BOM concept for data integration between the various information systems within a company. An et al. (2021) design an LCA platform for wind turbines based on IoT architecture and used IoT for the real-time collection of energy consumption and environmental impact data.

### *LCA and Blockchain*

Blockchain is used in the inventory analysis phase, the goal and scope definition phase as well as the impact assessment phase according to ISO 14040/14044. Figure 3 summarizes the applications of blockchain for LCA.

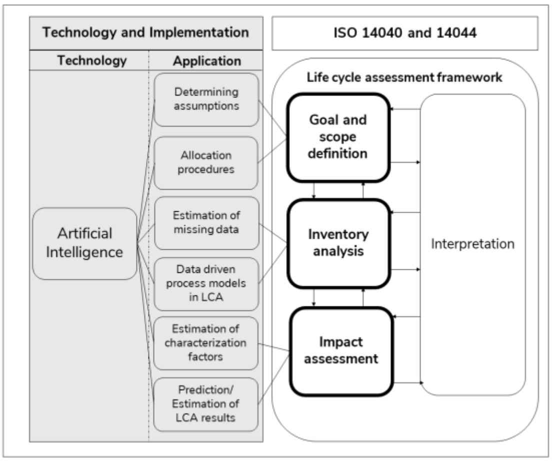

**Figure 3. LCA and Blockchain.**
Source: based on ISO (2006)

Blockchain can influence data reliability and enhance data traceability in the goal and scope definition phase and enables data exchange and serves as data storage possibility in inventory analysis phase. Shakhbulatov et al. (2019) investigate the use of blockchain for the tracking of the carbon footprint within food supply chains, with a special focus on the transportation stage. They use a combination of IoT and blockchain for collecting data directly from trucks. Shojaei et al. (2019) investigate the use of blockchain for the tracking of data needed for sustainability assessments within the construction industry. Their proposed chain of information enables LCAs based on reliable data given that the chain of information cannot be altered. Teh et al. (2020) study blockchain-enabled LCA and conclude that blockchain can help in tackling limitations of LCAs by sharing immutable and irreversible information in real time. Rolinck et al. (2021) develop a blockchain-based data management concept for the facilitation of LCA and apply it exemplary in the context of aircraft maintenance, repair and overhaul. According to Asif and Gill (2022) LCA results are impaired by the absence of real data from upstream and downstream supply chains and they propose a combination of blockchain and IoT for the collection of reliable, secure, and transparent data. They imply that blockchain can help LCA especially in the inventory analysis phase by facilitating the collection of reliable data in real time and in the impact assessment phase by enabling big data analytics for LCA researchers and practitioners to allow improvements of LCA results. Carrières et al. (2022) investigate how the use of blockchain traceability data can lead to improved LCA results by calculating a generic LCA and comparing the results to an LCA, which uses data from the blockchain traceability platform of an industrial partner. Lin et al. (2021) develop a framework for blockchain-based LCA and use blockchain for the secure transmission of inventory data from upstream suppliers to downstream manufacturers. Further in their framework every node can perform LCA calculation where this happens automatically, every time a node receives information about a material flow. Hence in the impact assessment phase blockchain can be used for automated LCA calculation. Also, Zhang et al. (2020) develop a framework for blockchain based LCA and integrate blockchain with IoT and big data.

### *LCA and Artificial Intelligence*

AI can be used in the goal and scope phase, the inventory analysis as well as the impact assessment phase. Figure 4 summarizes the applications of AI for LCA.

Regarding the goal and scope definition phase, Ji et al. (2021) use machine learning for the prediction of the building life span, hence for the determination of assumptions. Lopez-Andres et al. (2018) accessed machine learning for the determination of allocation procedures by testing three different allocation procedures, namely mass method, neural networks and stepwise regression.

In the life cycle inventory phase, AI can be used to estimate lacking unit process data. Zhao et al. (2021) develop a method for the estimation of missing unit process data by applying a decision tree based supervised learning approach. Khadem et al. (2022) focused on the optimal design of artificial neural networks for the prediction of CO2-eq data in order to fill data gaps of unit processes in the Canadian fuel life cycle. Toosi et al. (2022) developed a machine learning based optimization model regarding life cycle sustainability assessments which can be applied for the design process of new buildings as well as for energy retrofit measures. Machine learning in this process is used for the prediction of the energy performance of the building based on all possible combinations of the design variables. Given that the predicted energy performance is then used as input for the calculation of LCA results, this application is also considered as part of the LCI phase. Li et al. (2017) propose the use of data-driven models for modelling processes connected to the life cycle stages of the product, for which an LCA was calculated. They suggested that the machine learning based data driven approach can improve the currently expert knowledge-based modelling approaches.

One main application of AI in the context of LCA is the estimation and prediction of LCA outcomes. Various studies focused on the estimation of LCA results. For instance, Akhshik et al. (2022) used AI to perform a LCA estimation of greenhouse gas emissions reduction in the case of glass fiber-based composites being replaced by natural fiber-based composites. Khoshnevisan et al. (2014) developed an adaptive neuro-fuzzy inference system (ANFIS) to predict LCA outcomes based on the measurable inputs during the production season of farming. Płoszaj-Mazurek et al. (2020) used neural networks to estimate the carbon footprint of buildings during the design phase. Other examples of machine learning used in the context of LCA outcome predictions are: Zhu et al. (2020), Liao et al. (2020), Mayol et al. (2020), Martínez-Rocamora et al. (2021), Alam et al. (2021), Sharif and Hammad (2019) and Satinet and Fouss (2022).

Another application of AI in the impact assessment phase is the estimation of characterization factors. Hou et al. (2020) investigated the use of machine learning models for the estimation of ecotoxicity characterization factors. Slapnik et al. (2015) used machine learning for the estimation of not available characterization factors and Marvuglia et al. (2015) focused especially on the USEtox database regarding toxicity characterization in LCA. Gust et al. (2015)

explored the use of adverse outcome pathways as possibility to enable more accurate biological effects assessments within LCA. One of their approaches includes supervised machine learning models for the creation of quantitative adverse outcome pathways.

### *LCA and Big Data*

Big data can be used within the goal and scope definition phase, the LCI phase and the inventory analysis phase of the ISO 14040/14044 framework. Figure 5 summarizes the applications of big data for LCA.

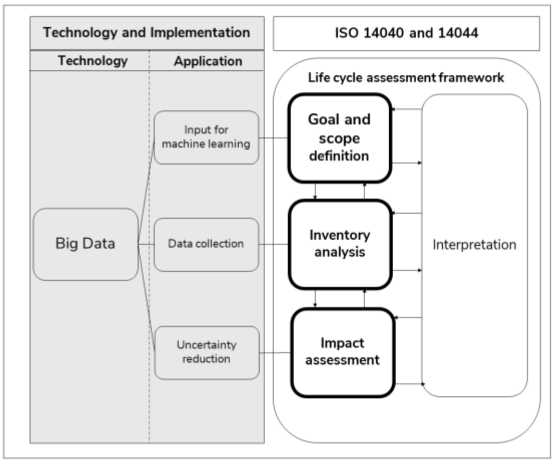

**Figure 4. LCA and Big Data.**
Source: based on ISO (2006)

Regarding data collection, Belaud et al. (2021) proposed a method for using data mining to obtain foreground data from scientific articles for completing the life cycle inventory**.** Yuan and Jin (2015) focused on building life cycle energy consumption assessment and the associated challenge rooted in the huge amount of data which needs to be processed. They stated that given the emergence of big data technology and building information model (BIM), the opportunity arises to conduct a full life cycle energy assessment by combining BIM, a data management platform and the data exchange between these two platforms. Hence, also their approach deals with data collection within the inventory analysis phase. Belaud et al (2019) investigated the integration of industry 4.0 and big data for the improvement of sustainability management in supply chain design. They designed a five-step approach and within this approach developed a big data architecture that delivers all data necessary for sustainability analysis.

Ji et al. (2021) used AI to predict the life span of buildings for LCAs where they used big data as input for their machine learning model. Given that the prediction of the building lifespan is set within the goal and scope definition phase, this also holds true for the use of big data as input for the machine learning model.
Regarding the impact assessment phase, Ross and Cheah (2018) studied the usefulness of high granularity use stage data for LCA. They used big data gained by pervasive sensing and concluded that the use of this high-granularity data reduces the overall uncertainty of LCA results.

## Conclusions

This contribution focused on the identification of applications of four selected technologies within the LCA phases according to ISO 1440/1444. To identify the applications, a systematic literature review was performed using the database SCOPUS. The results summarize the current status of how digital technologies can support LCA calculations: Whereas IoT is only applied in the inventory analysis phase, applications of blockchain, AI and big data are additionally also found in the goal and scope definition and impact assessment phases. The paper comes with the limitation of only using SCOPUS as database and not making use of snowballing to identify further relevant papers. These drawbacks will be taken care of during the further development of the paper and additional databases will be included and snowballing will be applied. This work can serve as overview for LCA practitioners and scholars to gain insights into the use of digital technologies for the determination of environmental impacts via LCA.

# Designing valuable GOODbyes: A review of state-of-the-art 'Design for Divestment' literature and its implementation in practice

**F.A. Poppelaars[a] & M.T. de Ruiter[a]**
a) Partners for Innovation, Amsterdam, the Netherlands

**Keywords**: consumer behavior; divestment; collection; design method; end-of-use; e-waste.

**Abstract**: Consumers play a crucial role in closing loops in a circular economy, as they decide how and when products are returned. However, the end-of-use of products is underexplored from a consumer perspective. This final phase of the consumption cycle, also known as *divestment*, is the process of the physical and mental & emotional separation of the consumer from their product. The field of 'Design for Divestment' is in its infancy.

This paper therefore explores the present situation of Design for Divestment in theory and practice and identifies knowledge gaps. The study first reviews the state-of-the-art literature and then analyzes divestment in practice. Interviews were held with inter alia Original Equipment Manufacturers (OEMs) and Producer Responsibility Organizations (PROs) to explore how the collection of e-waste is designed and how the divestment/consumer perspective is understood and integrated.

No universal factor could be found in literature nor practice to guide consumers towards collection solutions. Nevertheless, experimenting with different interventions at a small scale to design effective collection solutions seems to be key. It may be beneficial to engage consumers more actively during the design process and leverage their tacit and latent knowledge. Although the research field is not yet widely known by interviewees, divestment definitions, tools and methods in literature offer a base for designers. These could be complemented with methods commonly employed when designing for the purchase and use phases but adapted to divestment. Further research is needed to deepen and diversify Design for Divestment methodology and to bridge gaps between theory and practice to design valuable goodbyes.

## Introduction

The collection rate of e-waste needs to be improved drastically to reach European Union (EU) targets and attain a circular and sustainable Europe. Consumers have an essential role in closing loops in a circular economy, as they decide how and when products are collected. Despite their importance in this transition, the consumer perspective at the end-of-use of products is underexplored (Camacho-Otero et al., 2018; Selvefors et al., 2019), especially in contrast to the attention spent on the business perspective and technical perspective.

The term 'divestment' refers to the process of physical and emotional & mental separation from a product by the consumer during the last phase of the consumption cycle. 'Design for Divestment' considers how to design for this last phase of the consumption cycle from a consumer perspective.

This paper studies the current state of Design for Divestment research in theory and practice. Additionally, it uncovers knowledge gaps to guide further research in the field.

The scope of this research lies on the divestment of e-waste through their collection in the EU. We focus on business-to-consumer (B2C) activity, as the largest share (83%) of e-waste generated in Europe comes from this market (Fonti et al., 2021).

The first part of the paper provides an inventory of state-of-the-art divestment research identified through a literature review. The second part explores how divestment is understood and integrated in designing the collection of end-of-use electrical and electronic equipment (EEE) in practice. The final part discusses the main findings and knowledge gaps.

## State-of-the-art divestment literature

Let's first dive into the theory by looking into social sciences and design literature to uncover the state-of-the art of (design for) divestment research. This study builds upon previous work from a doctoral thesis (Poppelaars, 2020) and expands it with a literature study focusing on publications after 2020. This part defines divestment, its process, influencing factors, approaches, tools and design principles currently available.

### *Definition of divestment*

There is no consensus yet in literature on how to refer to the last phase of the consumption cycle from a consumer perspective. Various terms are used in literature, for instance, 'disposal', 'disposition' (Jacoby et al., 1977) and 'disinvestment' (Radtke et al., 2022). We use the term 'divestment' for this phase. Divestment combines both the physical and mental & emotional separation experienced by consumers when ending the use cycle of a product (Poppelaars et al., 2020). The physical separation stands for the visible part of divestment during which the consumer acts on their decision and transfers the ownership and responsibility of the products to another party. In contrast, the mental and emotional separation is the invisible part of divestment happening in consumers' heads. This part includes habits, biases, and the relationship with the product.

### *Divestment process*

Several models of the divestment process can be found in scientific literature in the fields of business administration and marketing (Blackwell et al., 2006; Cruz-Cárdenas & Arévalo-Chávez, 2018; Hanson, 1980; Roster, 2001), and in design literature (Macleod, 2021). In these different models, six stages can be recognized, as depicted in Figure 1. The figure provides a glimpse in the minds of consumers throughout the divestment phase:

1. **Dilemma recognition** occurs when the consumer reflects on whether to keep the product or to end its use cycle.
2. The consumer **searches for divestment options** (i.e., ways to separate from this product, such as selling, donating, collection or throwing away).
3. The consumer **evaluates these options** and chooses one, resulting in a divestment intention.
4. The product and consumer are **prepared for divestment**.
5. The consumer acts on their intention and performs the **final act of disposition** by physically severing with the product using the chosen divestment option.
6. The consumer ends the process with the **divestment outcomes** of the actions taken in the past stages.

### *Factors influencing divestment*

Most of the research in the field focusses on inventorying factors influencing divestment (e.g. Mohamad et al., 2022; Ting et al., 2019). These factors can be classified as product-, consumer-, context- or option-related, including for example attachment with the product, life events, environmental beliefs, convenience of divestment options, lifestyle, and social norms. Each of the stages in the divestment phase has its own set of influencing factors, but the studies do not point to a universal (set of) factor(s) to guide consumers toward collection. The factors are dynamic over time, interdependent and different for each consumer. In other words, the consumer is not rational but a complex being in an even more complex situation. These factors can thus not be used as predictive triggers to design collection solutions. Nevertheless, they do provide further understanding and important insights in the complexity of the divestment process (Poppelaars, 2020).

**Figure 1. Stages of divestment (Poppelaars et al., 2020).**

### *Design for Divestment approaches, tools and design principles*

Several publications offer Design for Divestment approaches, tools and principles to support designers with the development of valuable consumer divestment experiences.

Early research in the field has approached behaviour change at an individual level where consumers are rational. However, more recent research advocates approaching it at a collective level to deal with consumers' complexities and unpredictability. Encino-Muñoz (2020), for instance, considers the multi-layered and complex process by studying the divestment of clothing, furniture and mobile phones based on (social) practice theory (e.g. Reckwitz, 2002). Complexity theory (Nijs & Engelen, 2014; Webster, 2015) could also help to instigate change through emergence and adaptive methods (Poppelaars, 2020).

Master graduate Timmerman (2018) created the *tool 'Design for product detachment – Saying goodbye to a(n) …'* to help designers shape the divestment phase. It combines the consumer-product lifecycle with a divestment experience using a model of the process, value cards and behaviour cards.

Design endings pioneer Joe Macleod developed the *'Canvas for Consumer Endings and Off-Boarding'*. Macleod prescribes that "[a] good ending should be: consciously connected to the rest of the experience through emotional triggers that are actionable by the user, in a timely manner" (Macleod, 2022).The canvas prompts the designer with inputs on "where does it end?", "type of ending?", "how should it feel?", "what legislation?", "what are the phases?", and "how to measure?".

Lastly, Poppelaars, Bakker & van Engelen (2020) proposed *ten design principles* for the divestment of smartphones based on insights of seven design projects. These principles include e.g. "hold users by the hand to say goodbye", "think outside the divestment phase" and "consider the body and soul of devices".

## Divestment in practice

On this theoretical backdrop, this second part studies the advancements of divestment in practice for EEE. How is the experience of consumers understood and integrated in designing e-waste collection solutions?

Through semi-structured interviews, Producer Responsibility Organizations (PROs) and Original Equipment Manufacturers (OEMs) are asked how they design collection solutions for EEE and think about divestment. For completeness and when possible, these insights are supplemented with reports on the cases.

### *PROs results*

A large Italian PRO (personal communication, January 20, 2023) indicates that they mostly develop new e-waste collection solutions through an iterative design process by testing novel ideas through pilot projects. Integration of the consumer in this process comes through experience from previous projects, and conducting interviews and surveys. In other words, they mostly rely on empirical research when designing a collection solution. The PRO indicates that their main focus is on the convenience of their collection solutions, but they also try to inform the consumer about the relevance of gathering e-waste through speeches and small events about sustainability. The design of collection solutions by a large French PRO (personal communication, February 23, 2023) is thoroughly informed by consumer research to get a better understanding of what moves consumers. This goes beyond quantitative studies by complementing questionnaires with ethnological studies at collection points and with focus groups spread around France. The consumer knowledge is not anchored in scientific theories and models, but is the result of years of empirical research through various pilots and learning by doing to provide a wide array of collection solutions to consumers and instigate trust and new habits.

A Dutch PRO (personal communication, March 14, 2023) indicates that their collection solutions are strongly influenced by consumer behaviour. To closely involve and understand the consumer, the PRO employs methods such as focus groups, pilot projects and continuous evaluation with the target group through large scale surveys. They recommend segmenting consumers in lifestyle groups instead of demographic groups. The PRO uses insights from neuro marketing to leverage the subconsciousness of consumers to evoke the preferred behaviour. They recognise the physical, mental and emotional separation processes of consumers. Knowledge gaps mentioned are ways to retrieve stored devices, means to alleviate privacy concerns and further insights in how the specific type of EEE influences the divestment process.

The European-funded project COLLECTORS, executed in association with European PROs, "aims to identify and highlight existing good practices of waste collection and sorting", including e-waste (COLLECTORS, 2018). Case studies for social acceptance showed that citizen participation (e.g. focus groups, workshops and providing feedback) is one of the key elements of successful collection solutions. It acknowledges that "alignment – on the citizen's needs – is crucial and has to be taken into account when designing the measure implemented at the local level" (de Bree et al., 2019).

### *OEMs results*

A large multinational producing consumer EEE currently relies on collective collection solutions organised by PROs (personal communication, January 16, 2023). The company indicates that they are researching the viability of a take-back system for specific product categories. They are aware of design for divestment and are particularly interested in the added value that can be created by integrating the end-of-use of a product in their customer journey. To this end, they have explored several tools and models to understand and integrate the consumer in designing collection solutions (e.g. Fogg behaviour model, service safari, in-depth consumer interviews, personas, eco storytelling, service blueprint and co-creation sessions with designers).

Another EEE OEM, that also depends on PROs for the collection of their products, is currently exploring a business case for the development of a take-back program (personal communication, February 9, 2023). To them, its viability depends on the benefits gained by improving the relationship with customers compared to the costs of the implementation of such a program.

An IT equipment OEM has embedded the collection of their products in their value proposition (personal communication, March 23, 2023). Firstly, they try to postpone the end-of-use by offering various replacement parts and upgrade modules. When the use phase finally ends, they offer a take-back system that allows for the return of devices, regardless of the brand. The OEM indicates that their collection system is not financially attractive on its own, but fits with their company values and helps with customer acquisition and retention. The collection solution has a prominent place on their website and is combined with vouchers for a new purchase. The consumer is also triggered earlier in the customer journey through a message on the packaging indicating that the packaging is designed to be used to send the device back after its use. The OEM indicates that the consumer was not engaged during the design process of this collection solution and that it is mostly based on beliefs held about consumers through prior experiences.

## Discussion and Conclusions

Based on the results from the literature review and interviews, we can define state-of-the-art Design for Divestment knowledge and identify interesting future research opportunities in theory and practice.

### *Experiment, experiment, experiment!*

Although we are all looking for *the* universal factor that will stimulate consumers to return their products at the end-of-use, a clear conclusion is not reached in literature, nor in practice. The awareness, convenience and financial compensation of collection solutions are very relevant, but are not enough to bring everyone to action. As suggested in literature, consumers are not rational and can thus not be approached in a uniform and predictable manner. To navigate this, several interviewed PROs supplement surveys and interviews with experiments of collection solutions at a small scale, and iterate their interventions until they fit the targeted consumers. Experimenting with small groups by changing various interventions is in line with novel behaviour change approaches proposed in literature (i.e., practice theory and complexity theory) and could be further investigated.

### *Engage the consumer during design*

There also lies an opportunity in actively engaging the consumer in the design of collection solutions. The methods that the interviewed OEMs and PROs employ seem to rely on traditional explicit and observable knowledge. According to Sanders & Stappers (2012), two deeper levels of knowledge exist: knowledge from personal experience (i.e., tacit knowledge), and knowledge from thoughts and ideas on what has not yet been experienced, yet could have an opinion on it based on past experiences (i.e., latent knowledge) (Figure 2). These two deepest levels of knowledge remain largely unleveraged. Actively engaging consumers in design, for instance through generative sessions, may help in creating more effective collection solutions made with and for consumers. Some of the interviewed PROs and OEMs started exploring these knowledge levels to some extent, but it may be valuable to further research this knowledge gap.

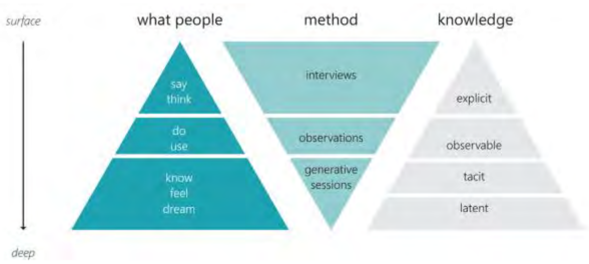

**Figure 2. Methods to study what people say, do and make help access different levels of knowledge (reproduction of Sanders and Stappers, 2012, p.67).**

### *Design collection as part of the customer journey*

Furthermore, as seen in literature, collection rates may be increased by making collection an integral part of the consumption cycle and by leveraging the relationship between consumers and OEMs. The interviewed OEMs recognise the potential of integrating collection solutions in their customer journey. However, they currently do not all have their own collection/take-back programs and are exploring their added value. Additional research is needed to substantiate these benefits (e.g. improved customer relationship, brand equity and recurring purchases).

### *Design for Divestment research as basis*

To perform the earlier mentioned experiments, designers need a direction for the required interventions shaping the collection solutions (e.g. collection point, campaign, hardware, software, service, packaging, etc). The definitions, processes, factors, tools and methods found in literature offer a good starting point for expanding knowledge within the emerging Design for Divestment field. Their robustness should be further tested and developed by for example investigating differences between product categories and brands (Radtke et al., 2022). Divestment as a concept is not yet widespread in practice, but piqued the interest of interviewees eager to get more knowledge on divestment to better understand consumers.

- Designers should consider the consumer when shaping the end-of-use of their products and services. To do so, following the definition of divestment, they could both take the physical separation and the mental & emotional separation process into account.
- The stages of divestment (Figure 1) can be used as a map of the mind of consumers. It starts at acknowledging that the product does not fulfil needs anymore, continues with searching and evaluating options, formulating an intention, preparing for it *and* acting upon it, and finishes with enjoying the result.
- To better understand consumers, more knowledge on patterns in factors and behaviour could support designers with design principles.
- The tools by for example Macleod and Timmerman can also guide designers in this still unknown territory of divestment and make the novel knowledge as practical as possible.

### *Learn from design methods in the purchase and use phases*

New design for divestment methods can be inspired by design methods that are commonly applied to designing products and services at the purchase and use phases, many of which recognise the consumers in their diversity and complexities:

- As argued by two PROs, segmenting consumer groups, neuromarketing and ethnography help guide the design of interventions for collection solutions.
- Different master graduates have used personas, service safari, consumer interviews, co-creation sessions with designers, and service blueprints

(e.g. Fan, 2022; Jingwei, 2018; Mertens, 2018; Polat, 2019) when designing collection solutions.
- Parts of the Use2Use design Toolkit could also be leveraged (Selvefors et al., 2019)

To conclude, the field of Design for Divestment is still in an early stage of its development and will need to be further deepened, diversified and consolidated. A foundation was created in both theory and practice to design valuable and effective collection solutions to keep EEE at their highest value and utility over time by closing the loop from a consumer perspective. We invite researchers and practitioners to bridge the knowledge gaps identified in this paper with further research to design valuable GOODbyes.

## Acknowledgments

The authors would like to thank Ronja Scholz (Fraunhofer IZM) for her review at an early stage and Jos Vlugter (Partners for Innovation) for his review of the final paper. The research leading to these results has received funding from the European Union's Horizon Europe 204 research and innovation program under grant agreement No 101058487 "INCREACE".

# How Blockchain Technology can contribute to Digital Product Passports for a Circular Economy

**Preut, Anna[(a)], Kopka, Jan-Philip[(a)]**
a) Fraunhofer Institute for Material Flow and Logistics, Dortmund, Germany

**Keywords**: Digital product passport; blockchain; circular economy; product life cycle information management.

**Abstract**: One of the core challenges for the transition towards a Circular Economy is the management of information and its transition between actors in order to enable and enhance the circulation of materials and components. However, much of the information needed to properly handle end-of-life products does not originate from e.g. the recycler but rather much earlier in a product's lifespan and is thus likely property of another actor. Authorities worldwide are debating and introducing concepts to handle this information in digital product passports (e.g. the European Union's upcoming battery passports as one of the most ambitious concepts). Blockchain technology promises to make digital contracts and information safe against tampering and falsification or at the very least provide means to verify the authenticity of digitally stored and distributed information. In general, this would bring benefits applied to the field of digital product passports where an interaction of (partly) unknown individual actors is the norm and no classic contractual relationship encompassing policies of information sharing is present. However, blockchain technology is controversially discussed especially regarding its environmental effects due to an often-high energy consumption. This paper aims to explore the overall compatibility of blockchain and digital product passports while assessing the benefits and boundaries linked to a combination of both in the context of the Circular Economy. It will present findings from a systematic literature-review and derives an overview of the chances associated with blockchain technology in the context of digital product passports as well as existing boundaries and challenges. Finally, a research agenda is laid out addressing the most important aspects to be further examined in order to assess the use of blockchain in this context.

## Introduction digital product passport

The transformation to a Circular Economy is a central topic in Europe and Germany. This is for example manifested in political strategy and position papers of the last 5 years, such as the European Green Deal (European Commission, 2019, 2023), the EU's Circular Economy Action Plan or the Digital Agenda of the BMUV (German Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection [BMUV], 2020). Among other things, the concept of the digital product passport is described in the publications mentioned as a promising enabler for this transformation.

The digital product passport is a digital information collection in which all product-specific information along the value chain from raw material extraction to recycling is stored centrally and made available for access by relevant user groups. It can, for example, provide information on the origin and composition of the product as well as on possibilities for repair and handling during or at the end of the product use phase. (German Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection [BMUV], 2020) Research institutions, industry associations and companies are already working in different industry and product contexts on the development and implementation of digital product passports, e.g. for buildings, furniture, clothing or container systems (GS1 Germany, 2023; Institut für ökologische Wirtschaftsforschung [IÖW], 2022; Madaster Germany GmbH, 2023; Vinnova, 2023). However, these have so far largely had a low level of maturity or are focused on optimising individual life cycle phases rather than the entire life cycle.

The development and implementation of a digital product passport that accompanies a product throughout its entire life cycle and contains all relevant information about it is associated with technical, organisational and legal challenges.

The implementation of a digital product passport requires that relevant data is collected in individual lifecycle phases (e. g. using sensor technology) and made available centrally across all lifecycle phases and different actors involved. Therefore, the technical framework for the collection and exchange of data between different actors has to be established. The provision of relevant information from all product life cycle phases requires the support of the actors involved. It must be considered that these actors pursue different economic interests and want their data to be protected and kept confidentially. Technical, legal and organisational framework conditions must therefore be created to support handling, exchange and storage of sensitive data from users and companies.

## Blockchain technology

Blockchain technology, most known for its application in the context of cryptocurrencies, is one of the most controversially discussed innovations in recent years. In particular, it is said to have the potential to convey trust in digital spaces and in the exchange of information between different actors. (Bundesministerium für Wirtschaft und Energie & Bundesministerium der Finanzen, 2019) Central features of the blockchain are that information is stored in the blockchain in a decentralized manner in the form of a constantly growing chain of information blocks. Consensus procedures and cryptographic mechanisms ensure that once information has been stored, it can practically no longer be changed. Changes (in the form of additions) to the blockchain are tamper-proof and traceable for all participants in the blockchain system. (Bundesamt für Sicherheit in der Informationstechnik, 2023) Depending on the use case, it is possible to choose between different types of blockchains, which differ, for example, in terms of their participation restrictions (permissioned vs. permissionless blockchain). (acatech, 2018) Due to its characteristics and its current popularity and proliferation, blockchain should therefore be considered as a possible technical basis for the implementation of a digital product passport. In a sustainability-related context such as digital product passports, the sustainability of the solution itself has to be considered. Several studies deal with different sustainability aspects of blockchain technology and address, for example, the associated waste generation or energy consumption (Digiconomist, 2021, 2022a, 2022b). These studies mostly focus on cryptocurrencies as the most prominent blockchain application. Depending on the type of consensus mechanisms used as well as the blockchain architecture, different degrees of energy consumption can be observed. In general, private or consortial blockchain networks have significantly lower energy consumption than public blockchains, which are used for most cryptocurrencies. However, compared to conventional centralised data storage solutions, they perform worse from an energy efficiency perspective. (Sedlmeir et al., 2020) Currently, there is no application-related, uniform and comparative study on the ecological impact of digital technologies in comparison or in relation to blockchain technology. Some authors argue, that, even if no sustainability advantage resulting from the technology itself can currently be proven, use cases can already be identified in which the use of blockchain technology can be seen as an enabler for increased sustainability (Rusch et al., 2022).

## Methods

To better understand how Blockchain technology and digital product passports can work together and be integrated with one another we have developed a three-stage approach. In the first step, a literature search was conducted in order to identify relevant literature on the intersections of blockchain and digital product passports focusing on cases in which both technologies are combined. Scopus was used as the database for this. Since the search terms TITLE-ABS-KEY(“digital product passport” AND “blockchain”) and TITLE-ABS-KEY(“product passport” AND “blockchain”) do not bring up any search results in Scopus , we adapted the term in order to identify more potential material to work with. We chose the term TITLE-ABS-KEY("blockchain" AND "sustainability" AND "digital") and limited the output due to the very common search terms “sustainability” and “digital” to open access review papers. This limited the initial results to 24 papers which were then screened based on their abstracts by both authors and categorised according to their relevance as “relevant”, "potentially relevant" and "not relevant". Five papers were identified as "relevant" by both authors and an additional eight papers were identified as at least "potentially relevant" by one author. Only papers that were "not relevant" for both authors were excluded from further analysis. Additionally, a web-search was conducted to identify further projects or grey literature that are related to the topic of digital product passports and blockchain technologies. We could identify several additional literature and projects that were also reviewed for this paper.

The second step was to review the full-text of the 13 papers, which were identified as at least "potentially relevant" in the first step for relevant statements / information on the following questions: (1) Does a linkage of digital product passport and blockchain generally make sense? (2) Does linking make sense in the context of the Circular Economy? (3) Are there any scientific findings regarding the ecological sustainability of the use of blockchain technology in the implementation of digital product passports?

Based on step 1 and 2, research gaps were identified and a case study concept was outlined in order to analyse and identify future fields of application for a combination of digital product passports and blockchain technology in a multi-stakeholder environment.

## Results

With regard to question 1 (Does a linkage of digital product passport and blockchain generally make sense?) (Alves et al., 2022) is the only of the 13 fully reviewed papers, which directly considers the linkage of a digital twin (which can be seen as similar enough to a digital product passport in order to be considered here) and blockchain. It describes blockchain technology as the best technology for implementing track and trace systems, such as a digital twin, in the Circular Economy.

However, some of the authors of the other papers read in full length also conclude in their literature studies that blockchain is beneficial for sharing and validating information among several different actors in a supply chain. This is justified in particular by the fact that blockchain makes it possible to share information between different actors in a tamper-proof way and thus create trust and transparency between these actors. (Alves et al., 2022; Khanfar et al., 2021; Pakseresht et al., 2023; Piscicelli, 2023)
(Khanfar et al., 2021) describe that blockchain can improve the availability of information and thereby contribute to an optimisation of activities along the product life cycle, such as product design or recycling, referring to (Leng et al., 2020) and (Agrawal et al., 2021). This is comparable to the objectives pursued with the introduction of digital product passports as a means to increase cross-actor information transparency in the Circular Economy.

With regard to question 2 (Does linking make sense in the context of the Circular Economy?) only four papers make clear reference to the Circular Economy concept (Alves et al., 2022; Pakseresht et al., 2023; Piscicelli, 2023; Rejeb et al., 2022).

(Piscicelli, 2023) addresses positive and negative social, economic and environmental sustainability effects of digitization in the context of a Circular Economy. The author describes, based on her literature review, that blockchain can improve traceability, trust, accountability and communication within a circular supply chain. (Pakseresht et al., 2023) identifies the reduction of information asymmetries, optimization of eco-efficiency, traceability and enhanced residuals valorisation as the four main aspects, where blockchain technology can contribute to the implementation of a Circular Economy. In the other papers, blockchain is described as a possible solution technology for use cases, e.g. in the circular textile economy, circular plastics economy and Circular Economy in the food sector (Alves et al., 2022; Pakseresht et al., 2023; Rejeb et al., 2022).

The additional web-search revealed further research and development projects and studies for different use cases in which blockchain technology is investigated or used to implement a digital product passport or a comparable approach for information provision and sharing. Some project examples are listed in the following:

- Battery Pass: the project partners develop a guideline on aspects of a digital product passport for industry und traction batteries in accordance with the pending battery regulation. The battery passport is supposed to enable a circular and sustainable battery supply chain. (Project Battery Pass, 2023)

- DIBIChain: the project team aims to develop a software demonstrator displaying information about a products life cycle and thus enhancing the circulation of the product based on blockchain technology (DECHEMA Gesellschaft für Chemische Technik und Biotechnologie e.V., 2022)
- ReDiBlock: the goal of the project is to develop a concept for a platform to exchange relevant data generated throughout a product life cycle in order to form the basis for decision making in resource-efficient recycling management networks based on distributed ledger technology (Karlsruhe Institute of Technology, 2021)
- (Agrawal et al., 2021) propose a blockchain-based framework for traceability in multitier textile and clothing supply chain in their study, considering e.g. difficulties associated with sharing of crucial and advantageous information between multiple stakeholders
- (Blümke & Hof, 2022) evaluate the use of blockchain technology for a concept of a digital product passport for batteries

The digital product passport is intended to contribute to better recycling of materials and products in the Circular Economy. Behind this is the goal of establishing more sustainable ways of economic activity. In this context, fundamental questions regarding the ecological sustainability of blockchain solutions must be considered. With regard to research question 3 (Are there any scientific findings regarding the ecological sustainability of the use of blockchain technology in the implementation of digital product passports?) two main findings could be obtained from the reviewed papers. As there is almost no direct reference to digital product passports in the read papers (only in one paper) and only in some cases a direct reference to the Circular Economy concept (four papers), however, these only relate to one part of the question, namely: scientific findings regarding the sustainability of the use of blockchain technology.

At first, in several papers the high energy consumption of blockchain solutions is identified as the prior problem or potential risk for economic and/or ecological sustainability, e.g. in (Alshahrani et al., 2023; Alves et al., 2022; Giungato et al., 2017; Lo Cascio et al., 2021; Piscicelli, 2023). Further, resource consumption, e.g. in the form of scarce raw materials, caused by building up the IT infrastructure required to operate a blockchain is identified as a potential risk for the sustainability goals pursued with the use of the technology. (Piscicelli, 2023)

Second, there are overall only very surficial and no detailed answers to question 3 to be found in the reviewed papers. Several authors see a research gap regarding the sustainable performance of blockchain and point out that projects and technology development in this context have not progressed far enough and/or that there are not yet sufficient scientific publications to make clear statements / conclusions in this regard. This applies not only to the ecological dimension of sustainability and to use cases in context of the Circular Economy, but also to social and economic sustainability and use cases in other contexts, e.g. bitcoins. (Giungato et al., 2017; Khanfar et al., 2021; Lo Cascio et al., 2021; Piscicelli, 2023; Rejeb et al., 2022; WU et al., 2022)

## Case study concept

None of the papers examined referenced case studies with links to the Circular Economy or product passports so that no direct blueprint could be derived. Based on steps 1 and 2 of the approach taken, research gaps can be identified that should determine future research in this field:

- Blockchain technologies and network types are diverse and still developing (and generally low TRL) for various applications, potentially spanning vastly different industries, business models and products. They need to be assessed and compared in order to identify the appropriate selection for a lifecycle-spanning system for trusted information exchange between actors.
- Data protection and data access are fields in which open questions regarding the right approach or level of protection and accessibility of information remain. Since blockchain entries cannot be altered, data privacy as well as the type of information directly stored on the blockchain are to be sensibly assessed.

- Finally, sustainability and energy consumption are aspects that lack appropriate scientific coverage. It remains unclear whether the potential ecological benefits of a digital product passport justify the high environmental impacts of a blockchain-based approach.
-

We suggest a real-world case study covering the entire product value chain and lifespan to address the research gaps identified. In order to produce results that go beyond the scope of currently available research, both blockchain-based and non-blockchain approaches should be explored and assessed in parallel. To ensure a broad coverage of cases across actors, sectors and business models, a complex product with a medium to long lifespan should be selected as the use case. An expected outcome would be a decision framework supporting users to identify the appropriate blockchain and digital product passport technology under organisational and ecological factors.

## Conclusions

The paper presents findings from a literature-review and provides an overview of the chances, challenges and uncertainties associated with blockchain technology in the context of digital product passports. Through research projects and studies, it becomes clear that a linking of the topics of blockchains and digital product passports is already being considered in a variety of use cases. Blockchain technology can address certain requirements of a product passport in terms of traceability, tamper-resistance, access regulations and trust-building between different actors. However, results from existing research and development projects have a rather low degree of maturity and several sustainability-related questions remain. A final recommendation for or against the use of blockchain technology for the implementation of a digital product passport is therefore not yet possible. The fields of research identified in this contribution can inspire future research on this topic. For this, developments (especially technical and regulatory) must continue to progress and application-related studies must be carried out with regard to assessing the suitability of blockchain technology, e.g. with regard to its ecological sustainability and in comparison, to other technological solutions.

According to the draft for the new Battery Directive (in 2020), industry and traction batteries, which have a capacity of more than 2 kWh, are supposed to be the first products for which a digital product passport ("battery passport") will be legally required from 1 January 2026. (European Commission, 2020) It is therefore to be expected that the development and implementation of solutions in this application area in particular will progress rapidly in the near future and that more precise statements on the research questions of this paper will be possible based on this.

# Resource-efficient luminaires – learnings from product re-design in context of lifetime

**Marina Proske[a], Sebastian Knoche[b], Jürgen Schwarz[c], Nils F. Nissen[a]**
a) Fraunhofer IZM, Berlin, Germany
b) Trilux, Arnsberg, Germany
c) Osram, Garching, Germany

**Keywords**: LED; luminaire; efficiency; LCA.

**Abstract**: Lighting and luminaires have made great improvements in the past with the introduction of LEDs. As a result, energy efficiency increased and therefore greenhouse gas emissions decreased significantly. However, material and resource efficiency are important as well and closely connected to product lifetime. While product replacement can be beneficial from the perspective of climate change as LEDs degrade over time, the resource efficiency is mostly determined by the product design and its longevity. Life cycle assessments of various luminaires show that efficient coupling of LED control units can help to reduce hardware and thereby reduce resource depletion without compromising energy efficiency.

## Introduction

In 2017, lighting accounted for about 15 % of global power consumption and 5 % of greenhouse gas emissions according to UNEP (2017). Lighting and luminaires have made great improvements in the past with the switch to much more efficient LEDs (Beu et al. 2018). Through higher energy efficiency, climate change impacts reduced significantly. However, material and resource efficiency are important as well and closely connected to manufacturing and raw materials of the lamps and luminaires. Resource efficiency is mostly determined by the product design and its longevity.

Within the ongoing research project SUMATRA, we looked into resource-efficient luminaires from the perspective of product design: how should luminaires, LED modules and drivers be designed to reduce the resource consumption without compromising the efficiency. Thereby, life cycle assessments (LCAs) are used to identify the hotspots in the design and evaluate re-designs to see if they actually lead to improvement.

## LCA of current luminaire designs

Within the project, LCAs of various industrial LED luminaires were carried out regarding the impact categories climate change (expressed as global warming potential – GWP) and resource depletion (as abiotic depletion potential – ADP). Production (incl. raw material acquisition and manufacturing), use, transport and end-of-life were taken into account, addressing the complete luminaire including the LED module (LEDM), LED controller (LEDC), housing, optics (mostly PMMA) and cables (within the luminaires). For the use phase, use in Germany is assumed, applying the German (current and predicted) electricity mix.

Results show that the use phase is the dominant factor regarding GWP, causing more than 90% of the impact (see Figure 1). Small changes in efficiency of the LEDs or LEDC already outweigh the impact of producing the luminaires over the lifetime. These results correspond with findings by Wu & Su (2021) and Ferreira et al. (2021), who studied similar industrial luminaires. Studies analysing LED lamps show slightly lower relative impacts of the use phase (e.g. Scholand et al. 2012. Bertin et al. 2019).

ADP is more strongly impacted by the production phase and thereby specifically by the LEDMs and the LEDCs and the containing precious metals in electronic components and the copper in the printed circuit boards (see Figure 2). Use phase is less relevant than production in total, but efficiency gains still relevant overall. These results correspond with findings by Ferreira et al. (2021) and Wu & Su

(2021) (the latter used a different indicator for resource consumption).

Comparison of different luminaires show that geometry, weight and number of LEDs correlate with the environmental impact of the production phase. The absolute impact is driven by the actual power consumption which increases with light output/number of LEDs. However, overall luminaire efficiency (Lumen per Watt) are important for the whole life cycle when considering not one luminaire as functional unit, but the light output.

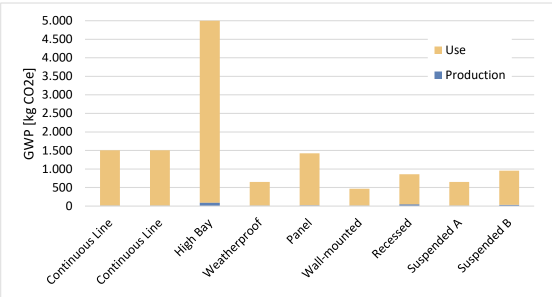

**Figure 1. GWP of different luminaires – absolute results.**

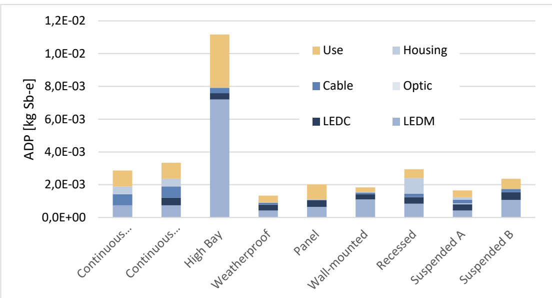

**Figure 2. ADP of different luminaires – absolute results.**

Scaling the impact of the lamps per 1000 lumen and 1000 hours (based on the individual lifetime between 50,000 and 100,000 working hours for the analyzed lamps), it can be seen that differences are much smaller and depend strongly on the overall efficiency of the lamp (Figure 3, Figure 4, Table 1).

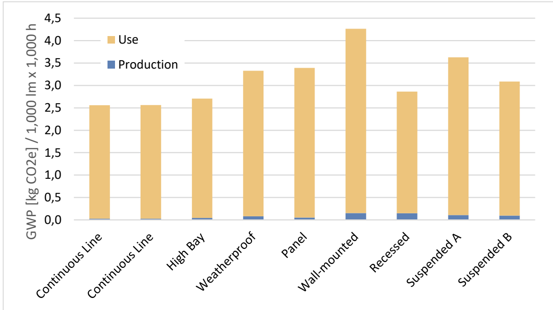

**Figure 3. GWP of different luminaires – relative to light output and lifetime.**

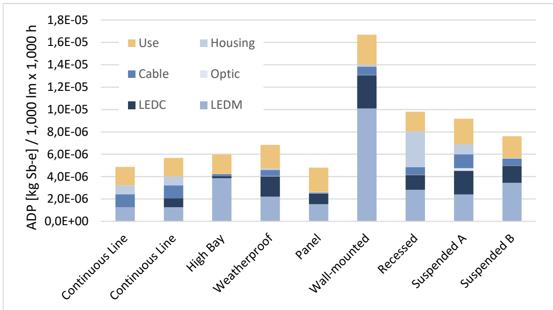

**Figure 4. ADP of different luminaires – relative to light output and lifetime.**

| Luminaire | Lifetime [h] L80 (45°C) | Efficiency |
|---|---|---|
| Continuous Line | 70.000 | 179 lm/W |
| High Bay | 70.000 | 170 lm/W |
| Weatherproof | 50.000 | 139 lm/W |
| Panel | 100.000 | 135 lm/W |
| Wall-mounted | 50.000 | 110 lm/W |
| Recessed | 100.000 | 167 lm/W |
| Suspended A | 50.000 | 129 lm/W |
| Suspended B | 50.000 | 151 lm/W |

**Table 1. Parameter of the analysed luminaires**

The question therefore is, how much light is actually needed. This starts with a good fitting luminaire fitting to the purpose (which and how many luminaires, how is the lighted area used) and is followed by an efficient light management system (LMS) which reduces light output and thereby energy consumption by dimming and occupancy control. A scenario how different LMS impact overall GWP and ADP, taking into account additional impact for the production of buttons and sensors is modelled (see Scenario LMS).

*Use phase and future electricity generation*

As shown, electricity consumption in use determines the main GWP impact and still a significant share if ADP impact. Studies such as Bertin et al. (2019) and Tähkämö (2013) already showed how the choice regarding the assumed electricity mix – in their cases European versus less carbon intensive French energy mix – impacts the absolute result and the relative impact of the manufacturing phase. As the service life of luminaires is very long compared to other electrical devices (e.g. 50.000 working hours and 2500 h/a result in a service life of 20 years), assumptions based on a static one year electricity grid mix can be misleading if the LCA study is not looking backward, but is intended to provide recommendations for current and future light installations. Especially with the on-going shift towards renewable energy in Germany (UBA 2021), the choice for the current mix or scenarios with slow or fast change towards more renewable energy has a strong impact on the overall result. Applying the current German grid mix to the full lifetime of a luminaire, most likely overestimates GWP impact of currently newly designed and installed luminaires. A positive scenario with a fast increase of share of renewables in the grid mix leads to less GHG emissions than applying the current grid mix throughout the lifetime. Depending on the specific scenario for the future electricity generation, the ADP will increase with sinking GWP due to high ADP-relevance of certain renewable electricity generation such as photovoltaic (Greening & Azapagic 2013).

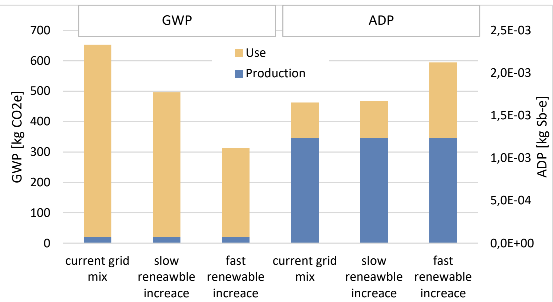

**Figure 5. Life cycle impact with different electricity grid mixes**

For our analysis, different grid mix scenarios were modelled using Sphera LCA to derive an annual GWP and ADP value based on the projected grid mix taking into account various fossil and renewable power generation sources. Figure 5 shows the impact of the same luminaire with the current electricity mix (UBA 2021), a fast and slow switch to renewables (Prognos et al. 2020, Pflüger et al. 2017). These show both, the strong influence on the absolute result but also the oposing effects for GWP and ADP.

Such effects make comparisons of absolute results across different use phase assumptions difficult. Not only will different electricity scenarios impact the result, also "how fast" the energy consumption is used, impacts the absolute results. Figure 6 and Figure 7 show the impact of the same luminaire with a different use pattern and therefore a different service life in years, leading to higher GWP/lower ADP impact for a luminaire with high use per year.

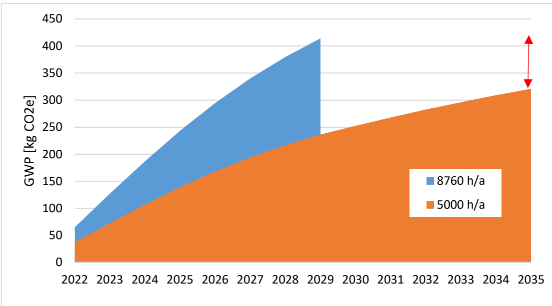

**Figure 6. GWP of luminaire use with 8760 h/a and 5000 h/a and same technical lifetime**

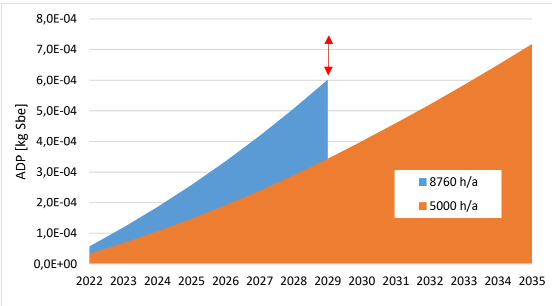

**Figure 7. ADP of luminaire use with 8760 h/a and 5000 h/a and same technical lifetime**

Assuming that many luminaires do not reach their technical lifetime, but overall service lifetime depends strongly on the use setting (as indicated by product category rules for environmental product declarations like IBU (2019) or PEP (2018)), this picture will change again. The manufacturing impact of luminaires with a long technical lifetime increases relatively (see Figure 8), showing not only the need to make luminaires stable and long-lasting, but matching needs and technical capabilities Especially for ADP, it shows that not utilizing the technical lifetime relatively increases the environmental impact of the luminaire manufacturing.

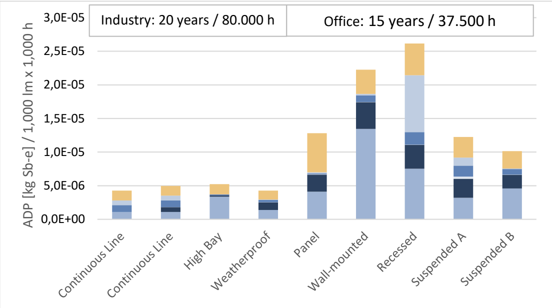

**Figure 8. ADP impact of different luminaires scaled per typical use-time.**

For GWP, the situation is different. Although the overall luminaire lifetime should be matched to the expected service life, lifetime extension is less relevant or even counter effective from a certain point. As GWP is driven so strongly from use phase and efficiency, early replacement can be relevant because LEDs degrade over time, resulting in higher energy consumption or lower light output. Ferreira et al. (20211) showed that the optimal replacement was after 18,000 h of use just from the perspective of reduced efficiency over lifetime. Results from Richter et al. (2019) also support replacement before the technical lifetime is reached in favour of more efficient LEDs from the perspective of GWP. Metal depletion, on the other hand, would benefit from longer lifetimes (Richter et al. 2019). Some studies, with single score results or a combination of impact categories (e.g. Bertin et al. 2019, Tähkämö 2013) result in lower impacts for longer lifetimes, again showing the need to balance climate change and other environmental impacts.

## Future Luminaire Design

Within the research project SUMATRA, a new more resource efficient luminaire design with the focus of commercial/industrial use should be developed without compromising energy efficiency. Thereby SUMATRA does not only focus on the improvement and reduction of housing and optical materials alone, but has an additional focus on an efficient design and coupling of LEDCs. In the following, two approaches for more resource efficient LEDCs are presented: a serviceable LEDC and a serial connection of luminaires to replace individual LEDCs. For the latter approach, an additional scenario addressing a complete installation incl. luminaires and light switches/management system (LMS) is analysed.

### *Scenario Serviceable LEDC*

In a first approach, a serviceable LEDC was designed with one main supplier unit and additional drivers for the individual LEDM. These drivers need less electronic components and have pluggable connectors to allow for easy exchange of individual drivers and LEDM without changing the overall luminaire.
A demonstrator for such variant with one controller and seven drivers replacing seven conventional LEDCs was assessed. The results show that although the impact per driver is lower than for the conventional LEDC, the much higher impact of the controller unit mostly outweighs these savings related to GWP and ADP (see Figure 9, similar results for ADP). Although this approach has many advantages in case of potential repair, these effect of actual improve the service life of a very few devices as failure rates are low (Ferreira et al. 2021). A different approach was needed to reduce actual manufacturing impacts.

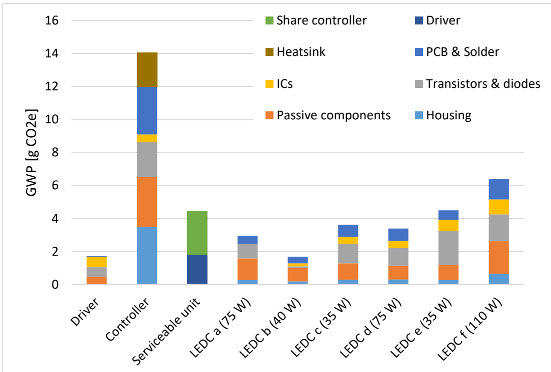

**Figure 9. GWP manufacturing impact of different LEDC options.**

### *Scenario Serial Connection*

The assessment of various LEDCs showed that impact of the LEDC manufacturing does not automatically increase with its power output. Therefore, for the second approach, conventional LEDCs were used but the number of LEDCs could be reduced by serial connection of the luminaires. In this way, three luminaires could be supplied and controlled via one 75 W LEDC instead of three 35 W LEDCs (compare LEDC c and d in Figure 9 and **Error! Reference source not found.**). Impact of the LEDCs per lighted area could thereby be reduced to ~45% of the initial impact for ADP and to ~30% of GWP.

*Scenario LMS*
As the developed solution for serial connection of several luminaires to one LEDC proved to be more efficient from ADP and GWP perspective, a scenario for classroom lighting was developed including 9 luminaires (suspended luminaire A), three LEDCs and as light management, either a conventional light switch, a dimmer or a wireless sensor (plus switch) for automated lighting management (different cable length for wired and wireless systems were taken into account). The use phase was modelled according to IBU (2019) with 2,000 h per year over 25 years of use. The preliminary findings are presented in the following and will be analysed in more detail within the project, also taking into account additional light management systems, which allow control across different rooms or building sections and via apps.

For this scenario, different hardware to control the lighting was modelled, for which different saving regarding energy consumption in use are assumed:

- Conventional on/off button: no savings
- Dimmer: 18% savings (IBU 2019)
- Sensor (plus switch) for automatic dimming and switching: 26% savings (IBU 2019)
-

Dimmers and sensors cause additional environmental impact through production of sensors and control units, but also additional standby power consumption in the use phase of the LMS and – in case of WiFi sensors – also about 100 mW additional standby consumption of the LEDCs, On the other hand, LMS save energy through presence detection (and/off) and daylight sensors to dim light. According to different guidelines (IBU 2019, PEP 2018) generalized savings through such systems can be applied between 25 and 45% of the energy consumption in use phase. Tests by Trilux on LMS showed savings of about 30 % (Knoche 2013). For the scenario calculated here, savings at the lower end were assumed according to IBU 2019.

The results are depicted in Figure 10 and Figure 11, showing that automated LMS are overall preferable when they lead to savings in the use phase, but from ADP perspective additional production impact are relevant but do not outweigh the efficiency gains in the presented scenario.

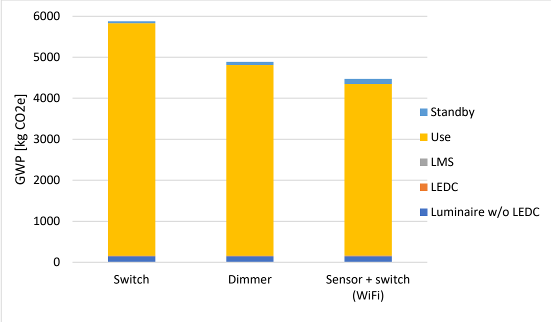

**Figure 10. GWP impact of classroom lighting with different light management systems.**

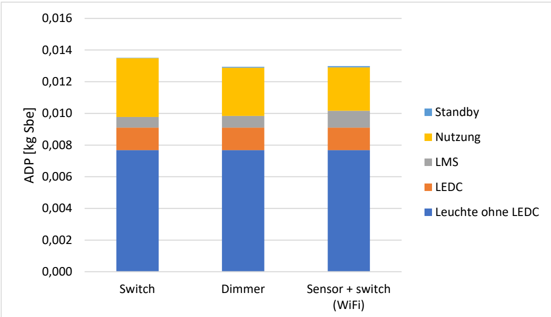

**Figure 11. ADP impact of classroom lighting with different light management systems.**

Comparing additional manufacturing impact and standby compared to reduced power consumption of the actual lighting shows that break even points are much earlier for GWP, but depend on the overall system. Small luminaires with low light output benefit less from LMS as bigger luminaires in connected areas with one connected LMS.

## Conclusions

Both impact categories benefit from LMS through energy savings due to lower light output also when additional manufacturing impact if these systems is taken into account, although there might be installations with small luminaires and low power consumption where extensive installation of sensors might not be worthwhile from ADP perspective.
Life time extension is relevant mostly from the perspective of resource efficiency. Regarding

GWP, lifetime extension is less relevant or even counter effective from a certain point as LEDs become less efficient over time. However, less carbon-intensive electricity generation in the future may reduce the relative impact of manufacturing and thereby delay these break-even points.

Either way, LEDs are much more efficient than most other lamp technologies, especially incandescent lamps, but still more than 7 billion incandescent lamps were in use worldwide in 2016 (UNEP 2017) and LEDs account for only about half of the current market for new lamps (Lane et al. 2022). So current focus of replacement should be on replacing other lamp technologies still in use before replacing aged LEDs.

## Acknowledgments

This work is part of the research project SUMATRA (consortium: Trilux, Osram, Fraunhofer IZM, Interseroh) funded by the German BMWK.

**Keywords**: Policy canvas; Circular business models; Sustainable fashion; Systems thinking; Circular economy.

**Abstract**: Currently, fashion is designed, produced and consumed within a linear economy. There is an urgent need for the industry to move towards a Circular Economy (CE), but this cannot be achieved without the alignment of policies. Policies relevant to the Fashion Textiles Industry (FTI) are scattered across various legislative domains with few attempts to harmonise them into a cohesive framework to support circularity ambitions. This research aims to systematically map circular policies relevant to the fashion industry in the European Union (EU), and identify policy gaps for further development. The research involved two stages. First, a systematic review of the academic and grey literature was conducted, which led to the identification of 30 EU policies. These were then categorised according to their level of maturity and analysed using an existing policy categorisation. Second, building on CE models and methods like the Butterfly diagram and the Flow Mapper, the policies were mapped onto a novel canvas. This method distinguishes the policies based on six dimensions: the resource life cycle phase, the CE loop (i.e. recycling or reuse), the CE strategy (i.e. narrowing, slowing or closing the resource loop), the policy environment (i.e. supportive or restrictive), the system element (i.e. resource, infrastructure, data, actor or value) and the circular business model (i.e. repair, resale, rental and remake).

## Introduction

The Fashion Textiles Industry (FTI) is increasingly recognised as unsustainable with a plethora of environmental and social impacts (Boström and Micheletti, 2016; Dahlbo et al., 2017; Niinimaki et al., 2020; Shirvanimoghaddam et al., 2020). So-called *fast fashion* is an exemplar of a linear production and consumption system; it has emerged as a dominant business strategy whereby clothing is produced with speed, volume and low cost as priorities (Niinimäki et al., 2020; Shirvanimoghaddam et al., 2020).

The Circular Economy (CE) has gained interest to transform how resources are viewed and managed, including in the FTI (Ellen MacArthur Foundation, 2017; Bocken et al., 2016). For transformative environmental, economic and social outcomes, a circular shift requires a systemic approach that incorporates the actions of diverse stakeholders, including policymakers, the private sector and citizens (Clube and Tennant, 2023; Niinimäki et al., 2020). Policy plays a vital role in initiating robust oversight approaches to create an institutional environment conducive to a thriving circular FTI and to support its demand-side uptake (Coscieme et al., 2022; Ellen MacArthur Foundation, 2017). It is important to investigate the regulatory landscape surrounding circular FTI since a lack of policy has been identified as a prevailing barrier to circularity as self-regulation has so far failed to induce radical change (Boström and Micheletti, 2016; Jia et al., 2020). Studies have indicated the crucial role that policymakers and authorities may play in transitioning to the CE (Jones & Jones, 2021; Kazancoglu et al., 2021), and the importance of having an integrated stakeholder agenda (Borrello et al., 2020; Hina et al., 2022; Kirchherr et al., 2018; Nußholz et al., 2019; Wasserbaur et al., 2022). However, academic literature on these policy topics is an emerging field in the FTI, with current research predominantly centred on identifying regulatory barriers and enablers for circular business model (CBM) implementation (Monciardini et al., 2022).

This paper responds to the call for a systematic understanding of the CE policies for FTI through an attempt to incorporate elements of CE models and methods (i.e. the Butterfly diagram (Ellen MacArthur Foundation, 2013) and the Fow Mapper (Zeeuw van der Laan et al., 2021). In doing so, the paper aims to present a systematic mapping of the EU's FTI policies, identify policy gaps, and subsequently recommend areas for policy development.

A novel policy canvas is introduced and used to map policies according to six dimensions, namely the resource life cycle phase (i.e. sourcing and production, distribution, pre-, in and post-consumption, and collection and recovery), CE loop (i.e. recycling and reuse), CE strategy (i.e. narrowing, slowing and closing the resource loop), policy environment (i.e. supportive and restrictive), system element (i.e. resource, infrastructure, data, actor and value) and business model (i.e. repair, resale, rental and remake). Building on existing CE principles, the canvas represents a novel theoretical contribution to the CE literature as it brings these principles together in a way that has not occurred before for the analysis of FTI policies. The canvas developed goes further in visualising the relationships between policies within and across multiple dimensions.

## Background Literature

Identifying and implementing effective regulation for CE is an area of expanding interest for governments, particularly in the Global North (Wasserbaur et al., 2022). The EU recognises the CE as a global mega-trend (Calisto Friant et al., 2021) and can be considered a forerunner in the international promotion of the CE (Winans et al., 2017). A report from the European Environment Agency (2019) highlights that, despite the key role which policy plays in enabling or constraining the CE, there is as yet, little analysis of policies across the resource life cycle. Approaches to mapping policy for CE take broad overviews across sectors (Domenech & Bahn-Walkowiak, 2019; Kautto & Lazarevic, 2020) or focus on one aspect of life cycle or policy (Maitre-Ekern, 2021; Svensson-Hoglund, 2021).

Despite the need for systemic approaches in CE policymaking, studies have so far predominantly attempted to map policy based on the type of policy instrument using established categorisations (e.g. regulatory, economic or informative) (Virta & Räisänen, 2021). Such approach positions policy instruments in a "continuum of an increasing degree of coerciveness" (Pacheco-Vega, 2020., p.621), drawing from Vendung's (1998), stick (regulatory), carrot (economic) sermon (informative) analogy. Young's (1996) categorisation, used within the field of land management policy, also accounts for voluntary measures, categorising policy instruments by motivational, voluntary, price-based, property-right and regulatory incentives. Such categorisation is useful for simplifying complex discussions of policy instruments and for establishing mixes of different approaches (Pacheco-Vega, 2020). However, on its own, it does not allow for analysis of the ways in which policies relate and interact across life cycle phases.

There are few attempts to map CE policy across the life cycle. Milios (2018), maps policies affecting resource efficiency in the EU, including those which have an indirect or partial impact, with policies categorised by three product life cycle phases (i.e. production, use/consumption, and waste management) and further divided into mandatory or voluntary. Hartley et al. (2020) draw on Milios' (2018) life cycle approach to outline policies which may accelerate or support a transition to the CE, and present recommendations drawn from experts across sectors including business, government and academia. A life cycle approach has also been used to map sector-specific CE policy related to plastics. Syberg et al. (2021), for example, review key legislation at each stage of the plastics value chain and map CE policy using a life cycle framework. Fadeeva & Van Berkel (2021) extend this by categorising policies using five resource life cycle phases (i.e. material input, product design, manufacturing and service provision, distribution and use, and end of (first) life material management). Areas of policy (rather than specific instruments or initiatives) to facilitate circular plastics are mapped onto the phases, illustrating the distribution of policies across the resource life cycle.

Attempts to scope policy pertaining to the FTI have been carried out in Latin America (Pastran et al, 2021), Australia(Payne et al., 2021) and Europe (Maldidni et al, 2021)reviewing existing and proposed policy interventions. These studies present an overview rather than a systematic or comprehensive mapping that enables careful integration of the technical elements and stages of CE when designing policies for a circular FTI.

## Methodology

Document review is the core method utilised in this study. Document review is an unobtrusive research method since the data is not influenced by the research process (Bowen, 2009). The approach involved the review and analysis of official EU policy documents relevant to the regulatory landscape of the FTI and the CE, as well as academic and grey literature document review. As a result, a policy dataset with 30 policy items was identified (see policies and policy sources in Table A in Appendix) and classified to include three types of policies: *established* (policies which have officially been enacted) (9), *in development* (policies which have appeared in EU communications but have not yet been enacted) (11) and *idea* (policies which have appeared in academic literature or EU studies) (10).

Then, a novel and systematic method to make sense of the FTI policy space was deemed necessary. Inspired by CE models and methods like the Butterfly diagram (Ellen MacArthur Foundation, 2013) and the Flow Mapper (Zeeuw van der Laan et al., 2021), a method to categorise policies was developed which allows to make sense of a policy dataset by distilling its complexity. The method involves mapping, clustering and tagging policies over a visual canvas (see Figure 1) using six dimensions each of which is presented along with its types and definitions (see Table 1).

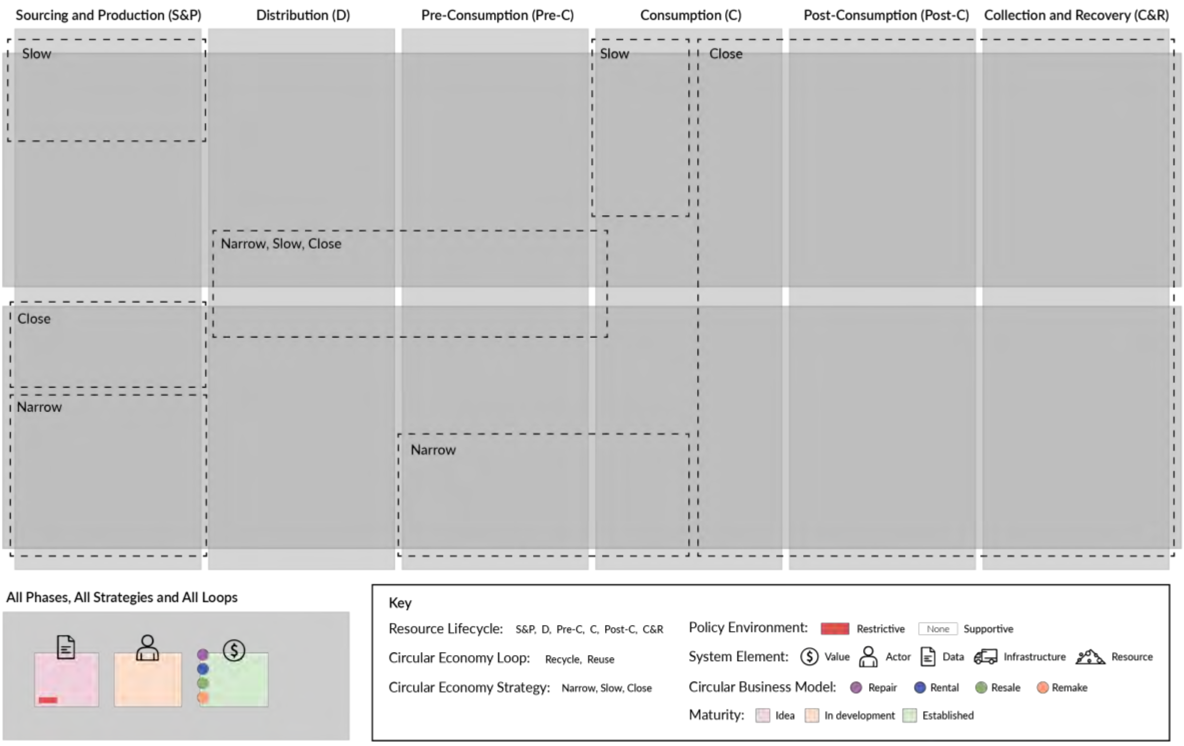

**Figure 1. Circular Policy Canvas template.**

| Dimension | Type | Type Definition |
|---|---|---|
| (1) Resource life cycle phase | Sourcing and production | Material extraction, material, component & product manufacturing. |
| | Distribution | Product transportation, delivery & storage. |
| | Pre-consumption | Product retailing, sales & acquisition. |
| | Consumption | Product ownership & use. |
| | Post-consumption | Product return for reuse, recycling, and disposal. |
| | Collection and recovery | Product collection, reconditioning, remake, material recycling & waste management. |
| (2) CE Loop | Outer loop (recycling) | Waste processing or converting into secondary raw materials. |
| | Inner loop (reuse) | Product or component reusing. |
| (3) CE Strategy | Narrow the resource loops | Reduce material usage in the product & production process. |
| | Slow the resource loops | Extend &/or intensify the utilisation period of product. |
| | Close the resource loops | Close the loop between recovery & sourcing resulting in a circular flow. |
| (4) Policy Environment (PE) | Supportive | Support the circular economy. |
| | Restrictive | Penalise the linear economy. |
| (5) System Element (SE) | Resource | Qualities & quantities of the resource including recycled material content, restrictions on materials, design requirements, etc. |
| | Infrastructure | Equipment & consumables including facilities, vehicles. |
| | Data | Information gathered & provided including advertisements, certifications, standards, labels, definitions, etc. |
| | Actor | Skills, actions, behaviours, etc. |
| | Value | Financial levy & incentives including fines, taxes, tax reductions, fees, contracts, tariffs, funds, etc. |
| (6) Circular Business Model (CBM) | Resale | 'Peer-to-peer sale of second-hand items, third-party marketplaces and own-brand re-commerce & take-back' (Ellen MacArthur Foundation, 2021). |
| | Rental | 'One-off peer-to-peer rentals by private owners as well as large-scale rental & subscription models by multi-brand platforms or individual brands' (Ellen MacArthur Foundation, 2021). |
| | Repair | 'A faulty or broken product or component is returned back to a usable state' (Ellen MacArthur Foundation, 2021). |
| | Remake | 'A product is created from existing products or components' (Ellen MacArthur Foundation, 2021). |

**Table 1. Dimensions used in the Circular Policy Canvas.**

## Results

The dataset of policies is initially categorised using the 'policy mechanisms' introduced by Young et al. (1996) and developed by Cocklin (2009), namely *direct regulation, economic instrument, voluntary instrument,* and *education and information initiative* (see Table 2). The policies are also presented in terms of their maturity level including *established*, *in development* and *idea.*

The policy mechanisms categorisation is found to subsume different dimensions such as degree of coerciveness, purpose and origin of policies. Despite its usefulness and widespread use, this categorisation does not provide a systemic assessment of policies that reflect the life cycle phases and specific CE characteristics like the CE strategies, loops, socio-technical elements and business models.

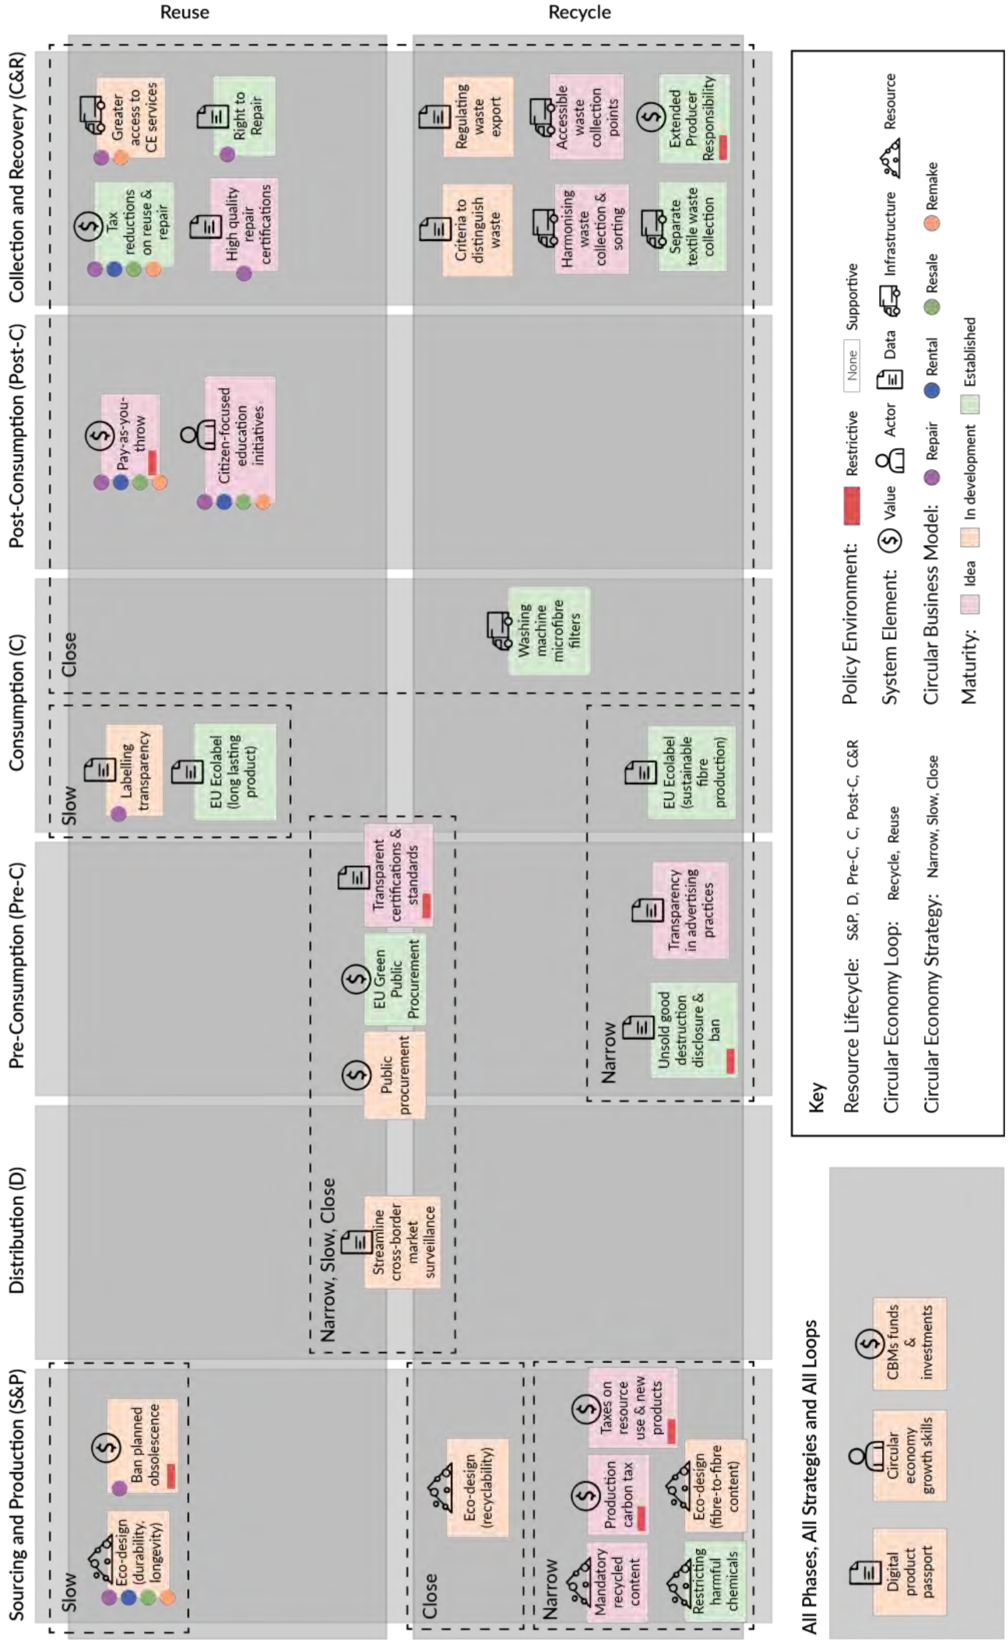
We, therefore, used the Circular Policy Canvas to map the EU FTI policies across six *resource life cycle phases* and two types of *CE loops* (see Figure 2). Using these dimensions, a policy is categorised over one of the six resource life cycle phases, as either addressing the outer loop of the CE that is recycling or the inner loop that is reuse. The policies are then clustered based on the *CE strategy* that they aim to support. Finally, they are tagged by the *policy environment* they create, *system element* they intervene on and some policies also by the *circular business model* they support.

| Policy | Descriptor | Mat. | Cat. |
|---|---|---|---|
| Restricting harmful chemicals | Restriction on the presence of chemicals in textile products to improve its environmental performance along its life cycle (EU, REACH). | E | DR |
| Unsold good destruction disclosure & ban | Obligation on large companies to publicly disclose the number of products they discard or destroy & bans on the destruction of unsold or returned textiles (France, Anti-waste Law; EU, ESPR). | E* | DR |
| EU Green Public Procurement | Companies are encouraged to use their purchasing power to choose goods & services with lower impacts on the environment (EU, GPP). | E | VI |
| EU Ecolabel | EU Ecolabel on textile products guarantees a more sustainable fibre production, a less polluting production process, strict restrictions on the use of hazardous substances & a long-lasting final product (EU, ECT). | E | VI |
| Separate textile waste collection | EU member states to establish systems for the separate collection of textile waste by 1st January 2025 (EU, WFD). | E | DR |
| Tax reductions on reuse & repair | Reduction on taxes, e.g. value-added taxes (VAT) on reuse & repair activities that keep products in use (Sweden, Further reduced VAT; EU, SSCT). | E* | EI |
| Right to Repair | Improve the repairability of products & empower citizens to repair (EU, Right to Repair Briefing). | E | DR, EII |
| Extended Producer Responsibility | Requirement for producers to take financial or other responsibility for the treatment & disposal of the products they put on the market (France, Environmental Code; EU, SSCT). | E* | EI |
| Washing machine microfibre filters | Obligation for all washing machines to be equipped with a dedicated microfibre filter as of January 2025 (France, Anti-waste Law; EU, ESPR). | E* | DR |
| Ban planned obsolescence | Ban on several practices associated with early obsolescence including planned obsolescence practices (EU, ESPR). | D | EI |
| Eco-design requirement | Product-specific eco-design requirements to increase textiles' performance in terms of durability, reusability, reparability, fibre-to-fibre recyclability & mandatory recycled fibre content (EU, SSCT; EU ESPR). | D | DR |
| Streamline cross-border market surveillance | Coordination and support for cross-border market surveillance practices in the EU & assurance of cross-sectoral coordination between different Administrative Cooperation Groups (EU, SSCT). | D | EII, DR |
| Public procurement | Leveraging the weight of public spending to boost demand for more environmentally sustainable products by setting mandatory criteria for the public procurement of these products (EU, ESPR). | D | EI, DR |

| | | | |
|---|---|---|---|
| Labelling transparency | Consumers must be provided with information at the point of sale about a commercial guarantee of durability as well as information relevant to repair, including a repairability score (EU, ESPR; EU, SSCT). | D | EII, DR |
| Greater access to CE services | Greater access to spare parts, upgrades & repairs, while taking into account affordability, boosting consumer convenience & giving consumers access to higher-quality products (EU, ESPR). | D | DR |
| Criteria to distinguish waste | Develop criteria to avoid that waste streams are falsely labelled as second-hand goods when exported from the EU, for example, making a distinction between waste and second-hand textile products (EU, SSCT). | D | EII |
| Regulating waste export | Export of textile waste to non-OECD countries is only allowed when such countries notify the EU of their willingness to import specific types of waste & demonstrate their ability to manage it sustainably (EU, RSW). | D | DR, EII |
| Digital product passport | Introduction of digital product passports enabling products to be tagged, identified and linked to data relevant to their circularity & sustainability (EU, ESPR; EU, SSCT). | D | DR, EII |
| Circular economy growth skills | Promoting upskilling, reskilling & acquisition and transfer of green & digital skills, including knowledge of LCA & value chain assessment (EU, SSCT). | D | EII |
| CBMs funds & investments | Promoting circular business (and start-ups and innovation) models through investment, funding & other incentives (EU, SSCT). | D | EI |
| Harmonising waste collection & sorting | Need to develop and harmonise collection & sorting policies (such as separate collection and management of textiles). | I | DR |
| Production carbon tax | A carbon tax targeting fashion corporations responsible for greenhouse gas emissions in their production processes. | I | EI |
| Taxes on resource use & new products | Increasing cost of virgin raw materials to raise the price of new products. | I | EI |
| Mandatory recycled content | A mandatory minimum percentage of recycled content for textile products. | I | DR |
| Transparency in advertising practices | Regulation requiring clothing advertising/ marketing to contain explicit reference to the carbon footprint of the garment & employment conditions of factory workers. | I | DR, EII |
| Transparent certifications & standards | Ensuring accessibility by the general public to a given item of clothing's environmental & social impact via establishing & publicising certifiable standards. | I | DR, EII |
| Pay-as-you-throw | Residents are charged for waste collection based on amount discarded. | I | EI |
| Accessible waste collection points | Ensuring textile waste collection services are easy to use & accessible so that residents are aware of it & reduces the effort of participation. | I | DR, EII |
| Citizen-focused education initiatives | Education systems to create awareness about the use of clothing, the environmental & social implications, facilitating repair, exchange & reuse. | I | EII |
| High-quality repair certifications | Certification of repair among workshops to guarantee the quality of the product. | I | DR, EII |

**Abbreviations.**
**Description:** ESPR: Ecodesign for Sustainable Products Regulation (European Commission COM (2022) 140); SSCT: Strategy for Sustainable and Circular Textiles (European Commission COM (2022) 141); REACH: Registration, Evaluation, Authorisation and Restriction of Chemicals; RSW: Regulation on the shipments of waste (European Commission COM (2021) 709); ECT: Ecolabel Clothing and Textiles; WFD: Waste Framework Directive; GPP: EU Green Public Procurement.
**Maturity (Mat.):** E: Established (E*: Established in one or more EU country only); D: Development, I: Idea.
**Policy mechanism category (Cat.):** DR: Direct regulation, EI: Economic instrument; VI: Voluntary instrument, EII: Education and information initiative.

**Table 2. Policies classified over the four policy mechanisms.**



Eco-design and EU Ecolabel: these instruments have been broken down into three and two components respectively to reflect their intent to address different CE strategies.

**Figure 2. Circular Policy Canvas.**

## Discussions and Conclusions

Mapping the CE policies related to FTI on the policy canvas points to several opportunities where policy support for a circular FTI can be strengthened in the EU. A close look at the maturity level of the policy landscape demonstrates that *established* policies constitute only a minority of all policies, with *in development* and *idea* policies jointly being the majority. This reflects the relatively recent emergence of CE as a policy idea in the EU since 2015 with the release of the first Circular Economy package (McDowell et al, 2017). As a result of its recency, the policy landscape remains fluid as the CE agenda in FTI evolves and matures. Practices of thorough policy mapping are particularly important in less established policy fields where policy gaps unavoidably exist. This paper employed the Circular Policy Canvas incorporating dimensions like the resource life cycle phase, CE Loop, CE strategy, policy environment, system element and business model in order to shed new light on areas where more CE policies are necessary to support the circular transition of FTI.

### *Imbalance of policies across the resource life cycle*

The findings show uneven policy support across the resource life cycle of the FTI. In terms of *established* policies in the early phases of the life cycle, there is only one policy in *sourcing and production* (i.e. Restricting harmful chemicals in REACH Directive) and none in *distribution*. There are, however, various policies *in development* and at *idea* stage (e.g. Eco-design requirements in EU Strategy for Sustainable Textiles). The sparse established regulation in *sourcing and production* is problematic given that fibre cultivation, textile processing and manufacturing entail considerable environmental and social impacts. The analysis also suggests that existing EU regulation is primarily concerned with *collection and recovery*, leaving limited *established* policy support in the phases of *pre-consumption*, *consumption* and *post-consumption* (i.e. EU Ecolabel and EU Green Public Procurement). Moreover, in these phases there are also few policies *in development* or at the *idea* stage. This has been observed as a shortcoming of the general CE policy approach in the EU (i.e. not FTI specific) (Maitre-Ekern, 2021; Milios, 2018). The phases of *pre-consumption* and *consumption* in FTI deserve further attention in policymaking as *collection and recovery* is a relatively late phase to recover value. Moreover, end-of-life interventions, such as EPR have limitations; industry may focus on shifting financial responsibility for waste management onto manufacturers rather than more proactive waste avoidance (Maitre-Ekern, 2021), such as in the case of the France textiles EPR (Bukhari et al., 2018). A focus on end-of-pipe solutions that is on *sourcing and production* and *collection and recovery* seems to only represent an incremental shift from previous EU waste management policy, suggesting policy layering and patching (Fitch-Roy et al., 2020).

### *Uneven distribution of established policies across the two CE loops*

Another area where immediate policy action is required relates to the CE loops. Our analysis shows that the majority of the *established* policies support the outer *recycling* loop instead of the inner *reuse* loop. This existing emphasis on recycling over reuse risks short-circuiting higher value reuse activities and business models (Clube and Tennant, 2023); reducing the ecological and economic value that can be created through a circular FTI. The focus on the *recycling* loop is further limited since there is currently a lack of scaled recycling technologies (Bukhari et al., 2018). To retain product value in the inner *reuse* loop, eco-design and other policies are needed that support design for sufficiency, reuse and maintenance.

Direct regulation policies are currently in development with the intention to increase “durability, reusability, reparability [and] fibre-to-fibre recyclability” of textile products and will be supported by information requirements (i.e. EU Eco-label, Digital product passports). Education initiatives will be needed to support actors to use and understand these labelling systems.

## Acknowledgements

The authors acknowledge the support for this research from the Transition to Zero Pollution initiative at Imperial College London through an Undergraduate Research Opportunities Programme (UROP) bursary awarded to Michela Puglia. We also thank the LISS DTP programme for supporting Lindsay Parkers' Research Assistant Internship at Imperial College London. Finally, we thank Valerie Boiten, Senior Policy Officer at the Ellen MacArthur Foundation for multiple insightful discussions over the course of the project.

# The devaluation of stockings

**Tone Rasch[a], Ingrid Haugsrud[b], Kirsi Laitala[b], Atle Wehn Hegnes[b]**
a) Norwegian Museum of Science and Technology, Oslo, Norway
b) Consumption Research Norway (SIFO), Oslo Metropolitan University, Oslo, Norway

**Keywords**: Product value; Repair; Historical analysis; Nylon stockings; Fashion.

**Abstract**: Consumer practices related to how we use and take care of products have changed throughout history. Especially within clothing consumption, the changes have accelerated in the Twentieth Century. In this paper, we use thin nylon stockings for women as an example product to see how their value, use, care, and lifetimes have evolved. The material is based on a literature review on nylon stockings from 1940 to today, accompanied by an analysis of consumers' written narratives from 1990 where people were asked to describe their use and memories of stockings and pantyhose. Our contemporary data is based on consumer focus groups on product lifetimes and plastic materials conducted in 2021 and 2022. The tight-fitting nylon stockings for women were launched around World War II by the American company DuPont. Cheap nylon substituted luxurious silk stockings and increased their popularity throughout the 1950s and 1960s. Around 1970, synthetic substances were devalued when fashion changed from elegance to more casual styles, and the political opposition to plastic as environmental damage and a symbol of the established society permeated the growing youth culture. Consequently, nylon stockings went out of fashion. Today, thin pantyhose is seen as disposable consumables with low value. Thin stockings represent a good example of how we value and take care of delicate items has a significant contribution to their lifetimes. Looking into the historical context is beneficial for learning about the points in time when changes occurred and how they contribute to consumer practices.

## Introduction

Consumer practices related to how we use and take care of products have changed throughout history. Especially within clothing consumption, the changes have accelerated in the Twentieth Century. In this paper, we use thin nylon stockings and pantyhose for women as an example of a product that first was recognized as high fashion but later has been devalued and is now seen as a disposable product.

Nylon stockings for women have been in use for 70 years. The appearance is quite similar, tight, silky and transparent, but the status has changed, going from fashion to anonymous everyday goods. This paper will discuss how the value, use, and lifetimes of thin stockings have changed throughout the past century. Is it possible to trace any connections between the amount of unwieldy and anonymous plastic waste characterizing today and the economic and cultural values consumer goods like textile fibres had before synthetic oil-based plastics were introduced in the 1950s? Our aim is that this analysis will contribute to a better understanding of how some objects have lost their cultural value and been invisible, though they never went out of use. This may explain some of the reasons for the huge waste problem the world is facing today.

Production figures from the global knitting industry show that the Datang Province of China, also known as 'Sock City', produced 13,5 billion pairs of socks in 2009, which is slightly less than two pairs per person on the planet. The estimated numbers of socks made in the world were around 40,5 billion pairs (Adrian, 2017, pp. 38-39). The sheer stockings and pantyhose segment is expected to grow further by a 3.3% Compound Annual Growth Rate for the next 8-year period (ReportLinker, 2023). In a recent study of textiles going out of use in Norwegian households, 9.7 % of the female clothing items destined for disposal were nylon pantyhose (Sigaard, personal communication, 16th March 2023). This indicates how immense volumes of waste the thin nylon hosiery creates annually.

This paper will go deeper into two research questions. The first will unfold the production story of nylon stockings in the Western World and especially Norway, as a part of the industrial reconstruction after World W II which included a major investment in the renewal of the textile industry. The second will investigate how nylon stockings became unfashionable in the 1970s, while consumption increased, prices decreased and opposition to plastic coincided with the introduction of single-use products.

## Methods

Artefacts, private archives and photographic documentation together with published advertisements, newspapers and magazines, will be central to the historical research together with literature within history of technology and fashion. This will be supported by a survey about clothing consumption carried out in 1990. Norwegian Ethnological Survey (NEG) manages a cultural history archive that collects and processes people's information about everyday life, in the past and present, by sending out questionnaires. In 1990, they sent out a questionnaire about clothing and accessories, which also included questions about use and attitudes to stockings and pantyhose (NEG, 1990). These questions were answered by around 130 participants and used here to enlighten the users' experience in the period before 1990, back to the first memories the participants had of these products.

For the contemporary data, we use descriptions from consumer focus groups that took place in 2021 and 2022. The first one was about product lifetimes where participants from six groups talked about products that they were either satisfied or dissatisfied with. The second project included three groups that discussed the use of plastic materials including synthetic textiles. Examples from these groups are used with citations in the paper to illuminate the current experiences and status of pantyhose. Citations are given with a pseudonym, the participant's age, and the year of the interview.

## Results and discussion

In this section, we focus on areas and periods where major changes have occurred that impact the status and value in production and consumption of sheer stockings and pantyhose.

### *Production*

Nylon stockings were an American invention, launched for consumers in 1939 (Meikle, 1995). In Norway, nylon stockings were first sold after World War II. The reputation had arrived before the desirable stockings, and they became immediately iconic. The nylon stockings became a symbol of the American lifestyle, like chewing gum and Hollywood movies. However, the stockings were in short supply. The import was highly restricted by the currency regulations after the war. The solution seemed to be domestic production. In 1950, five Norwegian factories produced nylon stockings (Hamar Arbeiderblad, 1950). Most of these knitting mills were well-established and had made stockings for decades. The new nylon fibre substituted or was added to fibres like wool, silk, or viscose.

A.S. Stephansen, also called Janusfabrikken after the trademark of the products, was the biggest producer of nylon stockings in 1950. They cooperated closely with the American fibre producer and inventor of nylon, DuPont, who produced the yarn. This was a part of the ongoing Marshall plan, helping European economies on their feet by economic and technological means from the US. Stephansen's trademark for nylon stockings was Jalon. A booklet from 1950 presented the new product for Norwegian consumers and described three important characteristics of nylon stockings: strength, durability, and elasticity. The text explained the technical characteristics of the fibre and the stockings and set up two different types of knitting techniques: single knit and mesh (Figure 1). The first type was the most common with high elasticity but had the disadvantage to rip easily. This technique was used for the thickest stocking qualities. The mesh was less elastic and less likely to rip or run. The technique was used for thinnest qualities (Janusfabrikken, 1950). These stockings looked quite different from today's nylon stockings. First and foremost, it was a pair of stockings, not pantyhose. And they were fitted with a foot and shaped to the leg. The stockings had seams at the back. Also, the material quality has changed as elastane fibres like Lycra were invented in 1958. The elastic fibre simplified the confection of the stockings as elasticity increased. The stockings needed to fit snugly on the leg.

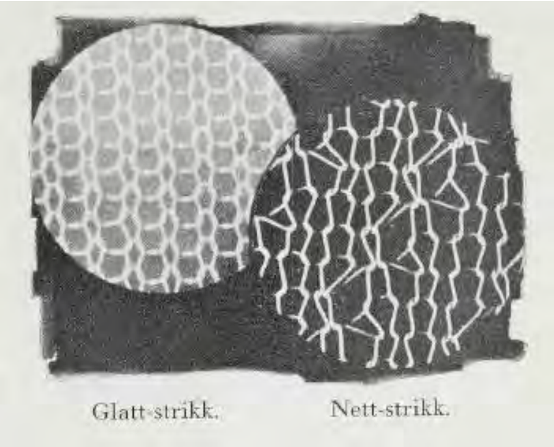

**Figure 1. Different knitting structures, regular single knit and non-running mesh (@Janusfabrikken, 1950, p. 10).**

The premises for the introduction of the nylon stockings for everyday use, was decided by the fibre plants and the hosiery industry. Chemical industries like DuPont were not only dealing with inventions and production, but also with fashion and marketing. The fashion industry including the fibre manufacturers largely determined the clothing style in the post-war period. The Stephansen's booklet was based on information from DuPont (Janusfabrikken, 1950, p. 2). This showed the connections between the industries and the impact they had on consumption.

As the economy of the Western European countries improved, the markets also opened to imports, and in 1957 the Norwegian import ban on textiles was lifted. Domestic factories stopped to produce nylon stockings around 1960. The huge clothing import to Norway characterizing the last decades, could begin.

### *Consumption*

The demand for the nylon stockings was implemented in the consumer culture in the 1950s. We have used the NEG respondents' rich and quite similar descriptions of their memories from the times that nylon stockings arrived. The first ones were received by those that knew people who had travelled abroad, and were first very expensive and valued items that were taken good care of, such as this description by a woman who was born in 1922: "*The nylon stockings really came to Norway after the war. Those who had relatives in the USA were among the first to receive them. We talked about these miracle stockings that were very expensive at first. But then they were very strong in return. […] Later, they became more disposable and were sold at a lower price*" (NEG answer 29606).

The changes in import of nylon stockings in the end of the 1950s were not immediately followed by changes in consumption. The consumer information continued to be about fashion and being well-dressed on the one hand, and hosiery maintenance on the other. During the 1950s, fashion was still about grown-up women. Dior had success with the New Look fashion line, characterized by tight waists and wide skirts that ended mid-calf. On the feet, there should be neat shoes, and between the foot and the edge of the skirt, the nylon stocking was perfect for the well-dressed. This style was well-received by all strata of the population and dominated fashion during this period (Partington, 1992). This was also visible in several advertisements, where the nylon stockings made the woman's legs more elegant.

The issue about maintenance was manifold. It was important to keep the stockings clean, whole and to protect the fibres so that they would last long. Much could be done by the consumer, and the industry was ready to contribute. The detergent company Lilleborg published the leaflet "A laundry manual for the home", which recommended the housewife to rinse the stockings in cold water after each use to maintain durability and elasticity (Lund, 2008). The leaflet was distributed to homeworking housewives, students and used in education in the mid-1950s. Janusfabrikken recommended washing stockings in a glass jar (Figure 2).

**Figure 2. Instruction for careful washing of stockings (@Janusfabrikken, 1950, p. 28).**

Ripped stockings had to be mended. The usual way to repair holes in stockings was with a needle and thread. But the nylon yarn was slippery and not always easy to work with. New machinery was invented to professionalise repair and make mending as invisible as possible. Several of the women in the NEG list described how the runs and rifts were mended: «*Ladders were pure disasters. We bought some small needles that were made specifically for mending ladders. But it was heavy and slow work*» (NEG answer 29474, woman born in 1921).

Professional hosiery mending businesses were also established. In Århus, Denmark the first opened in 1944, and in the 1950's there were 12 companies registered in the phonebook as their main business, just in this one town. The last remaining repair shop was registered in 1973 (Lundskov, n.d.). This was also the case in Norway where there are preserved mending machines in the collection of the Museum of Science and Technology. The efforts done to mend the nylon hosiery show that the stockings were launched at a time when maintenance and repair were still seen as valuable and that this may have contributed to the nylon stockings being seen as valuable in themselves.

The quality of the nylon stockings has been a consumer issue since the release (Figure 3). The first volume of the Consumer Report magazine (Forbrukerrapporten), published in 1958 featured a test of nylon stockings. Here, they described the production methods in detail and define terms like denier, which means the lower number the finer quality of the yarn in the stockings (Figure 4). They tested stockings as thin as 10 deniers and as thick as 60 deniers. It was stated in the article that "the correct stockings for the correct use are crucial for your stockings account" (p. 5). The statement was indicative of the normative tone of this period (Myrvang et al., 2004), and implied that the lifetime of the product depended on the user and her competencies. However, the journalist emphasised that the technological advances in production had led to stockings in finer yarns, and that "this, of course, has led to a great decline in quality". These [12 to 15 denier] stockings are thin, pretty and elegant, but have a relatively low use value" (Forbrukerrådet, 1958). Although the use value of these stockings was considered low even in 1958, this tendency continues in the years to come.

**Figure 3. Stocking quality control (@Janusfabrikken, 1950, p. 36).**

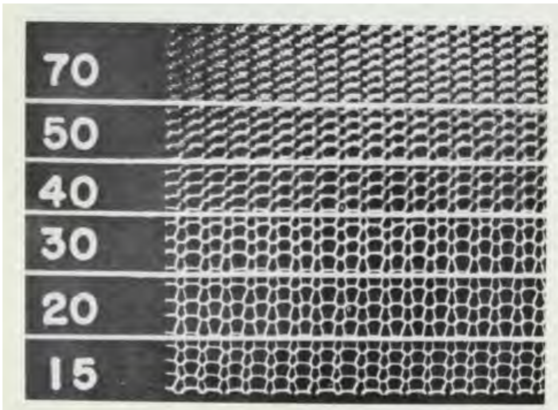

**Figure 4. Different thicknesses (denier). "The fine and thin low-denier stockings can of course not withstand the same as the higher deniers" (@Janusfabrikken, 1950, p. 13).**

Frugality was an important value in Norwegian society in the years following the second world war (Nielsen et al., 2011). The nylon stockings that were ruined beyond repair still had some lingering value (Türe, 2014) for consumers. "Discarded stockings can have several lives" was the introduction to one of many brief news items presenting ideas for alternative use of damaged stockings. Examples were to use stockings to pack your pleated skirt (Sandefjords Blad, 1962), dusting (Østerdølen, 1964) or for eel fishing (Pressens Spalteservice, 1966). Such tips continued into the 1980s but became fewer. Repurposing practices especially for hobbies might still occur today, but the main tendency is that the used pantyhose are discarded directly.

In the post-war period fashion went through profound changes. The 1950s style had implemented thin and transparent nylon stocking and in the 1960s the mini skirt opened for fancy hosiery (Chapman, 2002). Pantyhose became more important when miniskirts were in high fashion, as the "skirts would be shorter than the stockings were long" (Caputo, 2009). In the 1970s pantyhose had taken over the market from the former pairs of stockings (Chapman, 2002, p. 218).

However, the large increase in nylon consumption led to a corresponding drop in reputation (Handley, 1999, p. 125). The positive attitudes towards synthetics changed into negative opinions about falseness and cheapness. With the rise of the anti-materialist counterculture in the late 1960s and 1970s, synthetics contrasted increasingly with the ethos of naturalness and the rising awareness of ecological problems. The increase in production volume made possible by the synthetic materials led to a saturation of the market, and the novelty value of these products decreased (Handley, 1999).

The resistance to synthetics continued in the 1980s and 1990s. An American study from 1994 revealed statements like synthetics "does not breathe" and "feels inferior" (Handley, 1999, p. 127). Science journalist Kimbra Cutlip wrote in 2015 how "The mere mention of pantyhose ruffles some women's feathers" as they were "oppressive," "sexist," "tacky" and "just plain ugly" referring to a blog commenting on a pantyhose marketing campaign trying to re-invigorate the market among younger women. Another fashion journalist added that nylon hosiery was "a non-issue in fashion" (Cutlip, 2015). A review of Norwegian newspapers from the period 2010 to 2010 shows that nylon stocking was not on the agenda in the fashion reports. The nylon hosiery had sunk into oblivion within fashion.

The contemporary data confirms the negative attitudes to pantyhose. 32-years old Fiona (2021) complained: "*It [pantyhose] lasts once, or maybe not even a whole evening. Sometimes they unravel when you put them on for the first time, it's like that, I just think the durability is far too poor. It's not an expensive product, but it's like that, they're so disposable now… If they could withstand the washing machine and a couple, more than just a couple of uses, then that would be really nice*". This statement is similar to the citation from the woman who described her experiences with nylon stockings after the war, and was supported by the other participants from the most recent study. When asked about any single-use textiles, women in one of the groups came up in unison "*Pantyhose!*". Further, they described "*Yes, the 20 deniers are disposable. They're almost ruined before you put them on*".

Although consumers view sheer pantyhose as almost single-use garments, the quest for quality is still relevant. Women's magazines still run tests on nylon pantyhose (Gaden et al, 2022), and start-ups like Sheertex that rely heavily on Instagram marketing has gained attention for their 90-day guarantee and "impossibly resilient tights" (Sheertex, 2023), and was named one of Time Magazine's best inventions in 2018 (Time, 2018).

## Conclusions

The analysis shows that stockings used to be an expensive and valued item that was used and maintained with care. We see similar tendencies to other product groups especially within clothing, where the volumes have increased, and prices decreased with cheaper synthetic materials and improved automated production technologies. At the same time, some skills such as mending thin hosiery have disappeared, and in general, consumers do not take as good care of their clothing during use. As a rule, large changes in society such as war, regulations and development in materials and technologies have had an impact on our consumption patterns. Similar changes are likely to impact our future consumption, where for example extending the EU prohibition of single-use plastics to also apply for textiles would impact thin nylon hosiery production and consumption.

## Acknowledgments

The research is part of the "REDUCE - Rethinking Everyday Plastics" project financed by the Research Council of Norway (project-ID 326740).

# Textile Aesthetic Dialogues of Garment Mending

**Louise Ravnløkke**
Design School Kolding, Kolding, Denmark

**Keywords**: Garment appearance and lifespan; Design skills; Making mending; Material expressions; Textile aesthetic dialogues.

**Abstract**: Creative engagements with mending may cultivate change in how garments are perceived when breakage, time, and life appear as signs of wearing. Garment mending as a care and maintenance practice does not solely have the potential of extending clothing lifespan. Mending can also be seen as a bottom-up approach to altering a clothing culture through creativity and making. However, material expressions of mending are still to be researched to understand the influence on garment lifetime. This research is based on textile aesthetics and mending to better understand the material perspectives of garment repair. It discusses how designers can utilize their skills in materials and aesthetics to encourage engagement with garment expressions as a part of mending by providing support in creating a language of doing and verbalizing.

Rooted in design practice, this research is carried out through prototyping and full-garment sample-making in three encounters with mending, namely Material experimentation, Textile aesthetic materials as design tool, and Co-explorations with participants. The three encounters underline the complexity of mending. Mending a garment is not solely fixing the damage; it also requires the mender to consider the existing design of the garment and how to engage with that in relation to the damage.

In this paper, I discuss how designers can support making alterations to garments through a repair practice. By drawing on the preliminary findings of this research, textile aesthetic dialogues are suggested as an approach to which the designer can communicate and inspire consumers to feel confident in experimenting with mending as a medium of self-expression.

## Introduction

Garment mending is identified as one direction to extend the life span of clothing while slowing down the material throughput in the fashion system (Ellen MacArthur Foundation, 2021; European Commission, 2022). However, mending requires material knowledge and skills of how to engage with the damaged garment and mending techniques which may be challenging (Durrani, 2019; Gwilt, 2014; McLaren & McLauchlan, 2015), and together with low-quality and low prices of new garments, the motivation for repairing damaged garments is also low (Laitala et al., 2021). Extending the life of garments through repair is therefore multifaceted and revolves around systemic aspects as well as social and individual activities (Fletcher, 2016; Niinimäki et al., 2020).

From the perspective of garment design, a growing body of research is occupied with how garment repair can create resilience in the fashion industry to go beyond the point of purchase and impact the use phase. This has led to studies on garment design from a 'repair thinking' perspective which takes mending into consideration in the design phase and suggests alternative approaches to garment construction, product types and business models to make a new balance in the fashion sector (Durrani et al., 2019; Fletcher, 2008; Gwilt, 2020; Harvey, 2016; Niinimäki & Durrani, 2020).

Moreover, repair communities have been of research interest to obtain a broader understanding of these collaborative learning spaces (Durrani, 2019; Gwilt, 2014, 2020; McLaren & McLauchlan, 2015), as well as individual mending practices (Kucher, 2022). Since the establishment of the Repair Café Foundation in the Netherlands in 2012, we have witnessed growth in repair cafés as a part of a "Fixer Movement" (Durrani, 2021). Likewise, craft practitioners are creating awareness of creative engagements with mending techniques which is shared in viral realms and in a growing number of inspirational books. At a grassroots level, these initiatives are showing a shift of interest moving away from passive consumption towards actions on longevity on the level of the wearer and owner of garments (Niinimäki & Durrani, 2020).

Repair of garments, today, is often motivated by environmental preoccupations and the desire to reduce consumption (Durrani, 2019; Kucher, 2022). This retrieval of mending as a domestic craft is also recognized as a political statement of anti-consumption achieved by visible marks of the repair (Harvey, 2016; Shercliff & Twigger Holroyd, 2020). Contrary to historic fashion trends such as the punk movement and deconstruction employing raw expressions of rips, tears, open seams, and random placement of holes to break with tradition and demonstrate anti-establishment views (O'Hara, 1989; Zborowska, 2015), the drive of 'visible mending' is playing on beauty, skills and pride (Harvey, 2016). This acceptance of mending as a visual attachment to the garment dissociate from earlier social stigmas of economic hardship (Fisher et al., 2008; Gwilt, 2014; McLaren & McLauchlan, 2015).

Practicing mending, this shift away from an invisible repair makes an alternative pathway of mending where people can use it to express themselves. Repairing garments as a care and maintenance practice does not solely have the potential of extending clothing lifespan. Mending can also be seen as a bottom-up approach to altering a clothing culture through creativity and making (Fletcher, 2016). However, material expressions of mending are still to be researched to understand the influence on garment lifetime (Durrani, 2021).
With this paper, I what to substantiate the discussion of mending as an alternative pathway that may echo another aesthetic. Before taking this discussion further, the next section will outline a practice-based exploration of textile aesthetics and mending to better understand the material perspectives of garment repair.

## Method and Material

Rooted in design practice, this research is carried out through prototyping and sample-making for the purpose of generating experiential knowledge (Ravnløkke & Binder, 2023). The exploration consists of three design experiments which make the research program attain a greater level of abstraction by providing different objects of mending (Brandt et al., 2011; Redström, 2017). The data is, therefore, a triangulation of three encounters with mending, namely (1) Material experimentation, (2) Textile aesthetic materials as design tool, and (3) Co-explorations with participants. These experimental encounters were set out to explore how designers can facilitate engagements with mending (Kucher & Ravnløkke, 2023). This paper, though, draws on the material-driven practice of engaging with mending. In doing so, making mending samples is developed from a selection of full-garment exemplars representing different types of damages from everyday use, such as tears, spots, and holes. This study is concerned with cases of fabric breakage as opposed to repair of dysfunctional trims (e.g., missing buttons or broking zippers). The making of samples is therefore based on specific cases, yet to obtain a rich exploration of materiality and textile aesthetic engagements.

### *Material experimentation*

To achieve a first-hand exploration, I experimented openly with garment mending through my practice-based textile design skills. In this way, the engagement is both an exploration of the mending process as it is the gestalt of the full-garment samples (Albers, 2000/1965; Homlong, 2006; Rocha et al., 2021). Figure 1 shows a selection of the mending samples with a variety of garment types – some well-known styles (e.g., jumper and socks), some of the more specific characters (e.g., chemise and dress), fabric quality (fiber, construction, and density), and aesthetic appearance (color, print, etc.).

**Figure 1. Mending samples.**

**Overview of mending samples**
**1. Grey mélange socks. Worn-out material on specific areas (heals and ball of feet).**
**Mending concept: Swiss darning with one- and two-colored yarns. Color combinations contrast and blend in with base material.**

**2. Dark blue jumper. Torn hemlines of jumper.**
**Mending concept: whip stitch in matching yarn.**

**3. Floral print dress. Torn fabric parts (shoulder and short sleeve) on dress.**
**Mending concept: use of patches and embroidery with a variation of colors.**

**4. Silk chemise. Torn seams because of wear and tear (supporting areas)**
**Mending concept: use of patches and embroidery with a variation of colors.**

**5. Blue mélange jumper. Holes from infestation of moths.**
**Mending concept: needle weaving with one- and two-colored yarns contrasting the base-color.**

### *Textile aesthetic materials as design tool*

Co-exploring garment mending with participants was arranged as two participatory textile-making workshops (Shercliff & Twigger Holroyd, 2020). One was held at a NORDES design research conference (Ravnløkke & Kucher, 2021), and another at a public climate summit in Denmark (see also, Kucher & Ravnløkke, 2023). A selection of textile aesthetic materials was developed as a design tool to facilitate the social and material encounter of mending together with participants (Brandt et al., 2012). These comprise threads, yarns, and fabrics with different material expressions, such as smooth, rough, shiny, matte, textured, solid, and flexible qualities, as well as a color palette encompassing lighter and darker neutral tones accompanied by brighter accent colors (examples given in figure 2). Developing this selection draws on design practice and skills of working with textile aesthetics as a part of experimenting with design means as facilitation of garment mending. The selection was made to support a decorative approach to mending, as reconstructive and invisible repairs are more difficult and skills demanding.

**Figure 2. Textile aesthetic materials to facilitate garment mending.**

*Co-explorations with participants*

At the co-explorative workshops, participants brought a damaged garment they wanted to repair. Based on an introduction to different mending techniques and concepts of engagement, it was open to the participants to design and make their mending. Some participants already had a mending practice, others were beginners. In total 16 participants attended the two workshops and mended their damaged garments (figure 3).

**Figure 3. Examples of participants' full-garment mending samples.**

The process of making mending was observed and documented by photographing and taking notes. As it has also been noted from other studies with a participatory textile-making approach, the act of making and handling materials starts conversations about previous experiences and sharing of knowledge, as well as, the actual samples become a common reference point to reflect on taste, appearance, and materiality (Durrani, 2021; Shercliff & Twigger Holroyd, 2020).

*Data collection and analysis*

Altogether the practice-based exploration of textile aesthetics and mending has resulted in a range of full-garment mending samples and insights into related material processes. These empirical data are representing specific examples of rich and qualitative character. They are analyzed using a phenomenological approach to detecting the connections running through the three different material encounters with mending (Brinkmann, 2014). In the context of this paper, I am specifically looking at the material engagements and outcome of samples to better understand the material perspectives of garment repair, therefore the analysis and emerging findings already started to take form during the creation process (Revsbæk & Tanggaard, 2015).

## Discussion on Findings

In line with other research, this study confirms that mending requires skills and knowledge. Knowledge of mending techniques is one thing; another is material density and strength. As seen in sample d and e in figure 3, the same thickness of thread is used to mend a fine knit jumper (thin and very elastic) and a jean material (thick and tightly woven). Both are repairing a hole in the respective garments, the challenge lies in matching the repair (thread, needle size, stitches, and mending technique) with the elasticity and thickness of fabrics.

I will not dive further into mending techniques in this paper, yet it connects with the rather large material complexity of doing mending which is relevant when unfolding aesthetics and material expressions of garment mending. I will return to this material complexity throughout the discussion, as it is one of the findings appearing across the three encounters.

### *Material expression*

Making mending invisible is rather difficult. Therefore, in most cases, the appearance of the mend is intervening with the existing design of the garment. This requires the mender to consider to what extent the repair is to be seen. Two of the more experienced menders from the co-explorative workshops described their awareness of this issue: *"Sometimes, the damage is placed in areas where one does not want to attract attention"* and *"The place of the hole, seems like a decorative spot somehow"* (last quote relates to sample b, figure 3).

Developing ideas of how to engage with mending a garment connects with an analysis of the damage – the placement of it, the size, the amount, etc. A mending project, therefore, requires the mender to create an overview of techniques and aesthetic options for intervening with a damaged garment. This may also be a part of other garment-making activities as well, like e.g., knitting, but what differentiates is that knitting is usually made from the bottom and not as an alteration of another. Meaning that the mender needs to navigate another type of creative process similar to one identified in processes of up-cycling and redesign where the idea of the existing design somehow has to be broken down to see alternatives (Ravnløkke & Ræbild, 2022).

In the shown sample (figure 4), a pink tread is used to contrast the existing garment design by mending the holes in the blue jumper. This is one example of how choices of color create a pattern and new material expression when mending the jumper.

**Figure 4. Full-garment sample with repair of several holes.**

Looking further into approaches to mending may assist in understanding the creative process (figure 5).

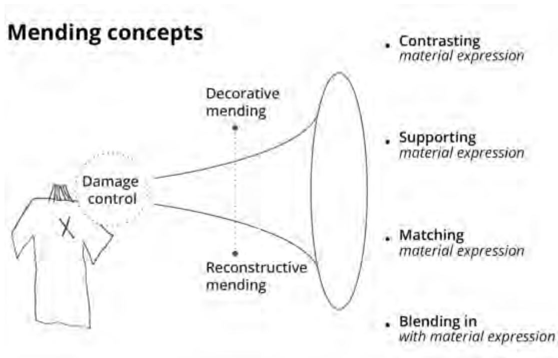

**Figure 5. Mending concepts – an overview of textile aesthetic engagements with mending.**

Moving from left to right within the spectrum shows three steps of repairing a garment: (1) controlling the damage, (2) approaching mending in a reconstructive or decorative way, and (3) intending a material expression that is *contrasting*, *supporting*, *matching*, or *blending in* with the existing garment design. All three steps relate to choices of material and aesthetic qualities which again underlines the complexity when engaging with mending while taking the appearance into account and not solely focusing on functional durability. In this process, the mender needs to navigate choices and possible outcomes that are hard to grasp from only thinking. Therefore, engaging with the material is key to training the sensory imagination. In connection to form-giving a design, Donald Schön (1991/1983) and Anni Albers (2000/1965) describes this process as a dialogic exchange with the material.

### *Textile aesthetic dialogues of garment mending*

The experimentation and co-exploration of making mending samples demonstrated how playing with the material guided them in finding the expression they thought suited their damaged garment. In this way, they familiarized themselves with materiality through this sensory engagement:

*"…going with the very close color match of the thread, I really like the organic texture that came to be. Moving in that grey area in between reconstructive and decorative – it's almost invisible at distance, but going closer you can see the craft and the woven pattern"* (see sample a, figure 3).

In the co-explorative workshops, the use of colorways and a selection of materials as a design tool for facilitation showed to give participants a safe playground for experimentation. Especially for beginners who were new to mending techniques and unfolding the aesthetic potential of garment mending. Having this textile aesthetic dialogue of colors, texture, pattern, etc. assisted the menders to form a language of doing and verbalizing. The textile aesthetic approach provided sensation and identity to find a personal expression of materials. Similarly, Durrani (2021) has, in her research on mending practices within communal repair, identified that training the sense of touch develops the mender's response to techniques and materials as well as taste.

Researching hand knitters' engagement with reknitting as a practice of re-use and repair, Twigger Holroyd found that examples helped participants "to grasp the diversity of what reknitted garments could look like, and begin to generate their own ideas" (2018, p. 99). Altogether this is stressing the importance of the tangible approach in developing the imagination of what aesthetics of garment mending might be.

## Concluding Remarks

Creative engagements with mending may cultivate change in how garments are perceived when breakage, time, and life appear as signs of wearing. Throughout this paper, I have shown examples of how the material complexity of garment mending reaches beyond skills and knowledge of techniques. Garment mending holds the potential to become a medium of personal expression, like other creative garment-making activities. Taking knitting as an example is also time-consuming and skills-demanding, as what has been identified to be a barrier to mending (Laitala et al., 2021), this does not hold back knitters from exploring techniques and aesthetics as a popular creative occupation. However, I have demonstrated in this paper that the process of garment mending differentiates from other creative garment-making activities, like doing a knitting project. Mending a garment, the mender is required to respond to the existing design of the garment, connecting with the damage. As such, the creative process of engagement cannot be systematized in the same way as e.g., a knitting recipe, and therefore demands another involvement. I suggest textile aesthetic dialogues as an approach to exploring avenues of materiality and aesthetic experience.

Future research aims to continue probing how designers in fashion and textiles well-developed skills in working with materials and aesthetics as a communicative tool to inspire consumers to feel confident in experimenting with mending.

## Acknowledgments

I will like to thank the participants from the co-explorative workshops and Simon Weinberger for giving valuable feedback on an earlier draft of Mending concepts.

# Durability of wind turbines – part of a sustainable energy transition

**Arne Remmen[a], Sofie Nygaard Rønnov Olesen [b], Michael Søgaard Jørgensen[c]**
a) Aalborg University, Copenhagen campus, Denmark
b) Aalborg University, Aalborg, Denmark
c) Aalborg University, Copenhagen campus, Denmark

**Keywords**: Durability; lifetime extension; wind turbines; circular economy; service contracts.

**Abstract**: A transition towards a renewable energy system is a necessary move to mitigate climate change and trying to keep the climate change below 1,5 degrees Celsius as agreed in the Paris accord. In the debate on renewable energy, it is sometimes argued that the manufacturing of wind turbines is causing substantial emissions. However, this discussion does consider the fact that the lifetime of the renewable technologies has been extended significantly over the past decade.
The focus is on the durability of wind turbines based on desk studies, interviews, and detailed case study of Siemens Gamesa Renewable Energy (SGRE). Wind turbines is an interesting case, since the actual durability and lifetime of wind turbines is much longer than originally estimated. The aim is to analyze the technological changes, the business models and the collaboration in the value chain that are determining the prolonging of the lifetime of the wind turbines.
Ten years back, the lifetime of a wind turbine was expected to be 15 years, but this was mainly a result of economic obsolescence as the public support scheme ended. The first offshore wind turbine park in Denmark was "demolished" after 25 years, and all the turbines still had a capacity factor > 90%. Besides, several turbines were refurbished and sold to other countries. Due to bigger and more advanced wind turbines, the manufacturers are experiencing more focus on durability and reliability from the customers, emphasizing the potential for environmental improvements. Additionally, "up-time", service and maintenance have become central part of the contract negotiations. Finally, the lifetime of the wind turbines can be extended by upgrading the control- and steering system, which at the same time can increase the capacity utilisation.

## Introduction

One of the central product strategies for enabling a transition towards a circular economy is to extend the product lifetime to minimize the use of resources, by using a product longer and potentially differently (Maitre-Ekern, et al., 2016). Durability has been subject to much research and is portrayed as a complex concept as variety of factors that can influence the durability of a product (Ardente, et al., 2014). Despite increasing interest there is a lack of consensus on how to define durability (Maitre-Ekern, et al., 2016). Various definitions highlight a products ability to maintain its properties (Ardente, et al., 2014; Mora, 2007), function (Dansk Standard, 2020a), and performance (European Commission, 2015b) over time.

Two definitions are commonly cited in the literature. One is the definition from the EN 455552 standard that defines durability as *"the ability to function as required, under defined conditions of use, maintenance and repair, until a limiting state is reached"* (Dansk Standard, 2020a). The other is from (European Commission, 2015b) where durability is defined as *"Durability is the ability of a product to perform its function at the anticipated performance level over a given period (number of cycles – uses – hours in use), under the expected conditions of use and under foreseeable actions. Performing the recommended regular servicing, maintenance, and replacement activities as specified by the manufacturer will help to ensure that a product achieves its intended lifetime".*

The two definitions vary in the activities they include. Some argue that repairability and durability are two sides of the same coin and should therefore be handled accordingly (Maitre-Ekern, et al., 2016). This correlate with the definition from (Dansk Standard, 2020a). This is however puzzling as there is a separate standard for repair and reuse, namely standard

EN 455554. Repair is not considered part of durability by (European Commission, 2015b) as it is a response to unforeseen actions that are difficult to predict and take into consideration at early stages. It can be difficult to differentiate between durability and repair as they both influence the lifetime of a product.

Durability is often used as a synonym for lifetime extension and the concepts are thus connected (Bobba, et al., 2016), and durability is explicitly described as a way to extend the lifetime of a product (Ardente, et al., 2014). (Alfieri, et al., 2018) highlighted that a product has both a functional lifetime (influenced by use of a product) and technical lifetime (determined by intrinsic qualities of a product). Another way to differentiate in the lifetime of a product is highlighted by (EEA, 2020a) who presented a framework where the lifetime of a product can be differentiated in its useful/actual lifetime, designed lifetime and optimal lifetime.

The lifetime of a product is determined both by the manufacture and the consumer (van Nes, et al., 2006). The relation between durability and the resource use and emitted emissions over the lifetime is complex as it is influenced by many factors. The effect of an increased durability of a product will vary across different product groups (Iraldo, et al., 2017).

## Durability – a short literature review

Durability have gained attention in the last decade due to the potential environmental, economic, and social benefits that can be gained from extending the lifetime of a product (Bobba, et al., 2016). The environmental benefits highlighted related to a reduced need for materials and resources across the life cycle of a product as well as less waste generation.
Durability is a design strategy for product integrity that aim to resist obsolescence and ensure long time use (den Hollander, et al., 2017). There exist a broad variety of strategies used to extend and improve the durability of a product such as: modular design, standardized components, repair service and/or information, maintenance service and information, ease disassembly using common tools, no use of glue or welding, high quality and robust materials or upgrade options (Hardware and software) (Remmen, et al., 2016; European Commission, 2015b).

According to (den Hollander, et al., 2017), the strategy applied must be supported by the business model and be integrated into the mindset of companies. Durability is highly influenced by both the manufacturer and the consumers/customers. The consumers role in product durability relates to the requirements they have when purchasing a product (Sun, et al., 2021), their use and application of a product (Bobba, et al., 2016) and their ability to repair and maintain, personal attachment and how they handle products at end of life (van Nes, et al., 2006). Consumers ability to purchase durable products depends on both the product design such as quality, function, materials, and composition as well as availability of information. This emphasizes the important role of manufacturers for enabling durable products. Other measures through which manufacturers influence durability are spare parts, production, warranties, standardization, and their business models (Remmen, et al., 2016; Oldyrevas, et al., 2020; Cordella, et al., 2021).

A challenge is to determine a durability design strategy for a product as obsolescence are determined by subjective factors. A product has both a physical durability and emotional durability, where the latter is somewhat overlooked in the literature but still very influential for the duration of use of especially consumer products.

An important distinction to be made is that lifetime extension does not ensure a more durable product as it is not guaranteed that the performance and functions of a product remains (Bobba, et al., 2016), a result being that durability might not always be the best design option. A related concept to durability is reliability. According to (Cordella, et al., 2021; Cerulli-Harms, et al., 2018) reliability is the preferred strategy both from a design-, consumer- and environmental perspective. Reliability of a product can ensure that it is I) more resistant for incorrect use, II) uses durable materials, III) can be adapted to future consumer trends, needs and functionalities (hardware and software) (Cordella, et al., 2021).

## Analysis and results related to wind turbines

The following analysis of the durability and the lifetime extension of wind turbines will give special attention to three aspects:

- Technological innovations of wind turbines
- Service contracts and business models
- Collaboration in the value chain

*Technological innovations*

The **technological innovations** of wind turbines are significant over the years. Back in the 1970'ties, wind turbines were looked at as "grass-root initiatives", and interestingly the first Danish manufacturers such VESTAS and Bonus (now SGRE) were producing machinery to the agriculture sector. In the 80'ties, the typical size was 75 kW turbines, and the development was based on trial-and-error and upscaling, and besides mainly owned and raised by farmers and "wind cooperatives" within the community (Karnøe, 1988). Late 2022, Vestas installed a 15MW prototype wind turbine with a height of 280 meters in a Danish test center, and one year after that SGRE installed a 14 MW turbine in the same place (VESTAS, 2022 and SGRE, 2021). In other words, the **size of the wind turbines** has increased significantly over the past 40 years.

This increase in size has only been possible due to a radical **optimization** of the construction of the wind turbines, which means a reduction in the economic costs as well as environmental footprint of CO2 pr. produced kilowatt. Researchers at Oxford University have calculated that the price of electricity from onshore wind turbines has declined with 70% from 2009 to 2019 from $135 to $41 pr. MWh. Together with solar photovoltaic, then onshore turbines are the cheapest way to produce electricity (Roser, 2020)

Before, the **durability** of the wind turbines was due to economic obsolescence, in the sense that the economic support from the government stopped after 15 years. However, since the wind turbines have become bigger, technological more advanced, and are installed without direct economic support, then the lifetime has become more in focus. In most cases, the estimated lifetime for onshore and offshore wind turbines are **25 years** e.g. in Environmental Product Declarations. When the building permit is for 25 years, then the turbines should last for 25 years. The longer durability of the wind turbines is also part of an increased material efficiency.

The lifetime of the wind turbines has often been underestimated to 15-20 years. When the Bonus wind turbines in the first offshore park were taken down after 25 years old, then their **capacity were still higher than 90%.** Besides, when the old Danish wind turbines are taken down, they are often **renovated, sold and reused** in other countries.

Refurbishment of existing wind turbines is done by updating the electronics and control systems, without changing the tower, the nacelle, and other costly parts. IT related upgrading is central, and smarter control systems make it possible to increase the load.

**Repowering** of old wind turbines is done continuously by changing to bigger and more efficient turbines. The old turbines can not necessarily be changed to higher turbines since this will require a new environmental impact assessment and/or a new building permit. In a current case, the utility in Copenhagen, Hofor and the wind cooperative, Middelgrunden will renovate and upgrade the offshore wind park just outside Copenhagen by installing automatic systems to steering and monitoring, e.g. the temperature in central components. A 25-year extension of the production permit has been applied for (Ing.dk, 2022). If approved, this will double the lifetime of the wind turbines. Due to the proximity to Copenhagen airport, it has not been considered to change to new and bigger wind turbines.

*Service contracts and business models*

The customers have changed over the years towards more institutional investors, and with an increased focus on durability since it has become part of the contract negotiations.

The customers do also demand a high **reliability**, where the contracts will include a so-called **uptime** with some minimum requirements to the time the wind turbines are producing. If the uptime is higher than the minimum requirements then both partners get a bonus, while if it is under then compensation is paid. In other words, an incentive to a heigh degree of reliability and uptime is built into the contracts, and these contracts play a big role in the development of service and business models in the wind turbine sector.

In the spring 2023, VESTAS has made a contract with a Brazilian customer on delivering and installing 36 4,5MW turbines combined with a 25-year Active Output Management service agreement. "This agreement will optimize energy production while providing long-term business certainty". (Press release, VESTAS 2023). The attention to **service and maintenance** has increased significantly, and SGRE has for a 455MW wind turbine park in Finland made "a 35-year full scope service agreement assuring the turbines operate at their maximum capacity over their lifetime (Press release, SGRE 2021).

**Revenue-based availability** has become an extra factor in the contracts as part of a higher degree of system thinking within the industry. Here, periods with low wind speed will be considered as part of the uptime structure, and this can be seen as part of a move, where the customer pay for a function rather than a product. This means that service and maintenance should be done in periods, where the electricity price is low. This area is changing fast, and was a few years back something special, while it today is part of the core business.

The wind turbines have plenty of **sensors** that provide the manufacturers with important data for making continuous improvements and innovations. The different components have each a QR-code due to traceability. This is part of an **internal traceability system** since there are limits for what SGRE can and want to tell. Even 99% of the information are known, then data related to the newest technologies are confidential. SGRE will rather easily be able to provide a **product passport**, if/when it becomes a requirement from the EU.

The demands from the customers do also give more attention to **environmental improvements.** Even price is still the primary factor, then more customers also have criteria for sustainability. However, different customers use different parameters in their sustainability assessments, where some highlights life cycle assessments, other energy use, etc. Establishing a consensus around the core parameters of sustainability will be a significant simplification, since it is quite a lot of administration for SGRE to answer the different questions and requirements from the customers.

### *Value chain collaboration and decarbonization*

As highlighted, there are several ways to extend the lifetime of the wind turbines due to both technological changes, and to service contracts and business models. At the end of the extended lifetime, then the main parts of a wind turbine are recyclable, but the blades and the magnets have been a problem.

For recycling of the critical raw materials in the **magnets**, the methods are in place and are economic feasible. However, the oldest wind turbines with direct drive are less than 15 years old, so the volume to do this on a big scale is not there - yet.

Both SGRE and VESTAS has been engaged in research and development of full **recyclable blades**. A challenge is that they so far are more expensive than the conventional blades. The business case is not fully in place. The recyclable blades have not been a direct demand from the customers, but the public expectation has been that this problem of recyclability was solved and that the blades did not end in landfills. SGRE is also looking into how to increase the recyclability of other components, and different labels about recyclability have been considered to inform and give the customer a choice.

**Take-back** and refurbishment of wind turbines has not been part of the business of the main manufacturers such as SGRE and VESTAS, since several other companies in the value chain have specialized in this field. In general, the focus of the manufacturers is on big projects with a critical volume.

The environmental discussion within the industry is currently on **climate, decarbonization and strengthening the collaboration** the value chains. The customers have an increased attention to the climate emissions from scope 3, where the main environmental impacts are. As an example, SGRE can cut down their scope 3 emissions with 50%, if they get steel produced on energy from renewable sources.

SGRE has mapped, how they can improve supplier relations, and has among things assessed 68 different suppliers. This mapping will be applied to compare their suppliers, and to include an environmental factor in the evaluation on top of the current price and quality factors. SGRE is expanding the value considerations from primary a focus on own operations towards focusing on all central **actors in value chain.**

An initiative in the procurement department of SGRE has attention to measurement and monitoring together with an expert in the field. The customers have an interest in this focus on climate and environment, including the materials. A wind turbine consists of 80% steel, and 50% of the $CO_2$ emissions come from the steel. Recycled steel has not been that high on the agenda in the steel industry, where the focus has been on optimization of the production technologies, and information on the recycled content in the steel is seldom.

## Conclusions

As highlighted, several reasons are behind that the durability of the wind turbines has been increased significantly from old expectation of 15 years to examples on service contracts on the wind turbines for 35 years. The reasons are to be found in a combination of both technological innovations, changes on service contracts and business models, as well as increased collaboration in the value chain.

Some of the highlighted developments can be summed up in these bullet points:

- Before **economic obsolescence:** support schemes for RE was for 15 years,
- ***Increased focus on lifetime*** due to bigger and more technological advanced turbines,
- Current durability is ***minimum 25-30 years*** for land- and offshore turbines,
- First offshore wind turbines were taken down 25 years old, and with **capacity still > 90%,**
- ***Reliability*** is in focus by customers – up-time is part of contracts,
- ***Service and maintenance*** are now essential in the business models,
- Extension of lifetime via ***upgrading*** of control and steering systems,
- Smart ***control- and steering systems*** increase capacity yield,
- New 455 MW wind turbine park in Finland - **service contract of 35 years,**
- Old Danish wind turbines are **renovated, sold and reused** in other countries,
- **Material efficiency has increased significantly** – bigger turbines = les material use pr. MW.

The technological innovations and the change towards service- and value-based business models are the dominant factors, but these are of course also related to changes within the value chain. The current climate challenges and especially the scope 3 emissions are putting extra demands on improving the collaboration with suppliers and customers to deliver decarbonization of the value chain including supplying materials such as steel and concrete with a low carbon content.

The environmental benefits of the extension of the durability and lifetime of the wind turbines are significant. However, these developments do also have a least one back-side. In the early days, the public support for raising wind turbines was significant since they were also owned and operated by farmers and wind cooperatives in the communities. With the increased turbine size and the professionalization of the industry with big manufacturers and institutional investors, then the NIMBY (Not-In-My-Back-Yard) effect has also become much more common. This has been tried to counteract by offering shares and benefits to neighbors within a certain distance, and it is also part of the reason for more attention is given to off-shore wind turbine parks than to on-shore.

## Acknowledgments

The paper is part of a larger investigation of durability of different product groups from electronics over industrial equipment to energy technologies. The investigation has been supported financially by the Danish Environmental Protection Agency.

Further, the information related to SGRE is based on an in-depth interview with Jonas Pagh Jensen, Head of Sustainability – Value chain engagement at Siemens Gamesa Renewable Energy.

# Circular Colour: Reusing Colour from Previous Textile Lifecycles in Textile Finishes

**Miriam Ribul**[(a)]
a) Materials Science Research Centre, Royal College of Art, London, United Kingdom

**Keywords**: Colour; Reuse; Circular Economy; Regenerated Cellulose; Textile Finishes.

**Abstract**: Colour is a key component of textiles, drawing interest while also changing with the seasons, which calls for a systemic perspective of its materials circularity in the context of future product lifetimes. To develop new design processes with regenerated cellulose obtained from post-consumer textiles, an exploration of solely undyed materials is not consistent with the reality that established design techniques produce a wide range of multi-coloured textiles. On the other hand, the presence of dyes reportedly impacts on chemical recycling, and conventional dyestuff for cellulosic materials is often oil-based and includes persistent dyestuff made up of unknown chemicals. Keeping the dyes of discarded textiles in a closed loop would replace the need for new dyestuff, reducing the use of water and energy for dyeing and de-dyeing processes, and avoiding the dispersion or landfill of potentially hazardous chemicals. This paper presents a textile technique that reuses the colour from waste textiles as the dye for cellulose-based textile screen printing processes. This was developed from the interaction and integration of textile design techniques with materials science processes for cellulose regeneration using a methodology developed by the author. When printed textile finishes reuse the colour from the cellulose source from previous textile lifecycles, no added dyes are needed, and the resulting mono-material textiles are compatible within the context of the circular bioeconomy. The results facilitate a material's future circularity, since the reused dyes do not disrupt the chemical recycling process in the regeneration of colourful, cellulose-based textiles for future product lifetimes.

## Introduction

In a circular economy, the transformation of waste textiles into circular materials, as achieved in scientific developments with regenerated cellulose, would restrict design techniques and show limited aesthetic capabilities as opposed to conventional textile processes when working solely with undyed cellulose resulting from chemical recycling technologies. Creating visual and aesthetic qualities with colour in textiles is a key skill attributed to textile designers. To this end, the circular materials practice presented in this paper considers colour in the textile value chain.

Conventional dyestuff for cellulosic materials is oil-based (Ellen MacArthur Foundation, 2017), but its chemical composition is largely unknown (Roos, 2016). Cellulosic fibres are dyed with either reactive, direct or vat dyes (Roos, 2016). Direct dyes do not need a mordant and attach to the fibre through a water bath process where increasing water temperature and salt aids the diffusion of the dye (Ingamells, 1993). Reactive dyes have small pigments that penetrate the fibre with excellent wash fastness since they are water-soluble in a bath with salt and fixed through an alkali (Ingamells, 1993). Vat dyes are not soluble in water and require a, 'strongly alkaline solution of a powerful reducing agent' (Ingamells, 1993, p. 101) to enclose the colour in the fibre, resulting in highly water, light and bleach-resistant textiles. In other words, these dyeing processes for cellulosic fibres require water, chemicals and high processing temperatures. Sulphur and azoic dyes are part of the category of water-insoluble dyes that are suitable for cellulosic fibres. Azoic dyes are categorised as a substance of concern as they have been shown to cause cancer and also because of their long-lasting attachment to the fibre (Ellen MacArthur Foundation, 2017). An additional impact that these dyes cause is created by the large quantity of water used—1kg of cotton requires fifty litres of water (Ingamells, 1993). Dyes can have hazardous impacts on the environment if the textile is landfilled (Ellen MacArthur Foundation, 2017).
The presence of persistent dyes made up of unknown chemicals reportedly impacts on chemical recycling (Elander and Ljungkvist,

2016). Coloured textiles require de-dyeing to remove substances from the cellulose that can hinder the stages of dissolution and regeneration (MISTRA Future Fashion, 2015). Dyes are fixed and can be difficult to remove. The molecular interaction between the dye and the fibre in the dyeing process defines the wash fastness, or in other words, the property of the dye meaning that it does not bleed out during a wash cycle. Most chemical polymer recycling technologies require the removal of the colourant, which is normally achieved by applying high process temperatures, water, and chemicals such as bleach (MISTRA Future Fashion, 2015).

Reusing the colour from the waste source in the new lifecycle of regenerated cellulose fibres is a recent approach for textiles. This is linked to the fact that the closed-loop chemical recycling of cellulose materials is also recent. Projects from Aalto University have demonstrated how colour from the material of the previous lifecycle has been retained for the fibre spinning process, which replaces the act of dyeing the regenerated cellulose once it has become a textile (Kääriäinen & Haarla, 2017). This paper presents the reuse of dyestuff from previous textile lifecycles in textile finishing processes.

## Colour in the textile value chain

Designers Thompson and Thompson (2014) state that in the textile value chain, colour can be applied by either stock dyeing fibres, dyeing yarns, piece dyeing rolls of fabric, dyeing finished products or garments, or by printing. They write that “[d]yeing uses the same chemicals as printing [...]; the difference is that dyeing involves immersing the material in dye solution to achieve a solid colour throughout, while printing is used to reproduce multi-coloured patterns and designs on the surface” (Thompson & Thompson, 2014, p. 240). They also state that:

> [P]rinted colour only penetrates the surface of textiles and does not go right through like dyeing, unless printing openwork or sheer fabrics. Printing is used to apply pigment ink. Pigments coat the surface of the raw material, as opposed to chemically bonding to its structure like dyes. Therefore, it is much more straightforward to colour-match with pigments than it is with dyes. The setback is that they are more vulnerable to abrasion and rubbing. (Thompson & Thompson, 2014, p. 242)

Research by the author established how a cellulose dissolution obtained from post-consumer textiles can be screen printed onto cellulose-based textiles for mono-material textile finishes (Ribul, 2023a, 2023b). In the context of the textile value chain, low value regenerated cellulose materials from waste textiles unsuitable for the fibre spinning process can be reused for finishing of cellulose-based textiles made of regenerated cellulose fibres obtained from post-consumer textiles, enabling a closed loop process for chemical recycling (Ribul, 2021). The objective of this research was to introduce colour into textile printing processes that are compatible with chemical recycling technologies for cellulose regeneration.

## Circular colour in textile finishes

The technique was developed using a Material-Driven Textile Design methodology developed by the author for textile design practice in materials science research during three research residencies in laboratories exploring chemical recycling of post-consumer textiles into regenerated cellulose: two residencies at RISE Research Institutes of Sweden and one residency at Aalto University (Ribul et al., 2021). The practice work began with a method to produce regenerated cellulose films (Ribul & de la Motte, 2018) and explored colour in the aim to develop new textile processes using regenerated cellulose materials which are inscribed within the circular bioeconomy.

The cellulose dissolution for regeneration in this technique followed a similar method to the preparation for fibre spinning: a cellulose source of postconsumer cotton was dissolved using ionic liquid solvents: 1-Ethyl-3-methylimidazolium acetate (EmimAc) during the residencies at RISE; and Aalto University’s patented Ioncell solvent in the third residency (Michud et al., 2014). The cellulose dissolution was then regenerated using a water or ethanol-based coagulation bath (Ribul et al., 2021).

The practice work built iteratively on a series of experiments for the introduction of colour. Material tests in the first residency established the capability of a regenerated cellulose film to bond with a substrate and subsequent studio practice identified a transfer of colour from other materials such as wood using bioplastics with similar properties. Material experiments in the second residency showed that an un-dyed, post-consumer cellulose source resulted in a transparent regenerated cellulose film that is not very visible on white cellulose-based fabric substrates (such as cotton, viscose and lyocell) for textile finishing techniques such as printing. In this residency, sawdust, synthetic flock, glitter and post-consumer milled cotton were used to enclose physical colour in the form of particles into the films, which however resulted in uneven and undefined colour as opposed to conventional synthetic liquid pigments explored for textiles screen printing in the following studio practice. Prototyping in the third residency then introduced dyed post-consumer cotton, milled with a Wiley mill and dissolved using the method described above for a consistent and even colouration of the cellulose dissolution for textile screen printing. Several processes were tested to achieve a pigmented dissolution that would create a visible print finish in the practice outcomes which are described in the next sections.

## Barriers to circular colour

The aim of creating a specific colour range proved more complex than the conventional textile process of blending pigments into water-based binders for screen printing. Several barriers towards the chemical recycling of dyed and finished textiles were identified. These required additional processes to analyse and modify the cellulose source in order to dissolve it.

### *Turquoise: post-consumer garment*

To create a turquoise colour in the cellulose dissolution, the practice work introduced a dyed ten-year-old garment that had been washed several times and had a label stating that the material was made from one hundred percent cotton. Seams, prints and labels were cut out from the garment to avoid non-cellulosic materials (such as synthetic threads, prints and labels) entering the chemical recycling process. The first dissolution experiment did not dissolve the turquoise milled post-consumer cotton. Viscosity tests were performed in collaboration with a materials scientist that showed that the degree of polymerisation could not be measured. This indicated either a high degree of polymerisation where the material has not sufficiently degraded for the dissolution (Palme, 2017), or that there are cross-linking agents present in the dyes or finishes of the textile, disrupting the dissolution process (Smirnova, 2017). Cross-linking agents can bond the dye more strongly into the fabric or create bridges between finishing molecules and fibre molecules (De la Motte, 2012). The dyed fabric was soaked in a chemical solution to remove potential finishes, washed in water and dried in an oven at 40˚C. The chemical treatment did not yield any results when a second dissolution was tested and the cellulose source did not dissolve in a result similar to the first experiment. The dominating factor limiting the dissolution was the potential of unknown chemical cross-linking agents in the finishes of the textile. The analysis, chemical treatment and failed dissolution tests demonstrated that a dyed garment labelled as one hundred percent cotton can contain high levels of unknown substances that disrupt recycling possibilities and require harsh chemicals to remove them.

### *Cyan, yellow and magenta: ‘100%’ cotton fabrics*

Small samples of dyed cotton fabrics in a cyan, magenta and yellow colour range were sourced for their shade and for their one hundred percent cellulose-based content. However, the fabrics could not be milled. Burn and stretch tests evidenced a synthetic content in the plain weave fabric that hindered the milling process, signposting a potential elastane content that showed a slight shine and melted during burning. Therefore, it was not possible to dissolve the textile samples. The experiment highlighted how fabric labelling often does not correspond to the composition of the textile.

### *Red: recycled cotton textiles*

A red dyed, organic recycled cotton fabric could also not be dissolved. Viscosity tests highlighted a high degree of polymerisation in the cellulose chains caused by insufficient degradation of the fabric through wash and wear (Palme, 2017). A sulphuric acid wash degraded the fabric to facilitate the dissolution process. This same process is also recorded in Smirnova’s account of the dissolution of several dyed fabrics (2017). The dye effluent in the sulphuric acid wash can be avoided with a higher degradation of the cellulose source.

## Circular colour

The final practice work used three types of pigments in the screen printing process. The colour sources used achieved transparent to opaque prints.

*Red: recycled cotton textiles*

A sulphuric acid wash to degrade a red cellulose-based recycled cotton fabric led to a significant loss of dye during subsequent washes of the milled cotton. The milled cotton was then dried and a colour change from red to an orange shade pointed to a chemical transformation in the dyes during the dissolution process. The milled, red post-consumer cotton in figure 1 was introduced in subsequent textile techniques in the practice work. Another change in colour took place when the cellulose film on fabric was regenerated in an ethanol coagulation bath. If regenerated in water, the orange colour stayed on the fabric and resulted, however, in brittle films (Figure 2).

**Figure 1. Red recycled milled cotton (2018).**

**Figure 2. Orange cellulose dissolution on fabric (2018).**

*Black: charcoal*

After experiments with dissolving post-consumer dyed cellulose sources failed, possibilities of adding compatible dyes to un-dyed post-consumer cotton cellulose sources were explored by sourcing charcoal. Granulated charcoal is a non-toxic organic material that can be derived from wood ash. The charcoal was added to the post-consumer milled cotton at the cellulose dissolution stage. The dye required no additional chemicals to bond to the cellulose in the dissolution, and resulted in a visible print (Figure 3). At the chemical recycling stage, the wood-based dye can be regenerated with the cellulose material or safely biodegrade.

**Figure 3. Charcoal-dyed dissolution on fabric (2018).**

*Blue: vat dye*

A light blue milled post-consumer cotton was dissolved to generate another colour (Figure 4). The light blue shade of the cellulose dissolution was not visible when screen printed onto fabric. A stronger blue shade was obtained when the vat dye corresponding to the dye in the cellulose source was added as a pigment into the dissolution process. The resulting dark blue shade was visible when printed onto fabric and demonstrated that the dissolution can be re-dyed to achieve a stronger colour (Figure 5). Re-dyeing by adding chemicals in the form of pigment is not suitable for a closed loop chemical recycling system. On the other hand, the vat dyeing process did not add a reacting agent normally required for fixing the dye to a fibre.

**Figure 4. Light blue milled cotton (2018).**

**Figure 5. Blue cellulose dissolution on fabric (2018).**

## Conclusions

This technique reuses the colour from waste textiles as the dye for the cellulose-based dissolution in the textile screen printing process. The dye makes the regenerated cellulose film visible when it is printed as a finish onto cellulose-based fabric substrates. The results also demonstrate several opportunities for dyed mono-material finishes using waste textiles by bonding dyes to the cellulose dissolution without adding chemicals. When the technique reuses the colour from the cellulose source, no added dyes are needed in the finishing process and the resulting mono-material textiles are compatible with the context of the circular bioeconomy. The technique facilitates a material's circularity, since the reused dyes do not disrupt the chemical recycling process of cellulose-based textiles. Therefore, various dyed cellulose dissolution experiments can potentially be combined to match colours while the cellulose is still in its liquid state, similar to the mixing of pigments in conventional screen printing techniques. This could provide more possibilities for blending colour in the finishing process and requires fewer dyed waste cellulose sources to achieve more colours.

Multiple barriers were identified in the chemical dissolution of dyed textiles. A classification could be carried out, distinguishing between the different types of cellulose source dyes that would provide specific colour ranges in textile finishing using regenerated cellulose materials. The classification of dyes could extend in order to consider cross-linking agents that disrupt the chemical recycling process. Abrasion, wash and colour fastness tests could be performed in future research.

The cellulose dissolution for the finishing process however can use low value cellulose waste that is not suitable for fibre regeneration (Ribul, 2021), and results in mono-material cellulose-based textiles designed for future product and material lifecycles. This work can have future implications for research and practice that explore strategies for reuse of materials and products before recycling takes place.

## Acknowledgments

With thanks to the Centre for Circular Design at Chelsea College of Arts (UAL), where this PhD research was based, and to supervisors Kate Goldsworthy and Carole Collet. Thanks to Hanna de la Motte and RISE Research Institutes of Sweden as well as Aalto University for hosting practice elements of the research. This paper was supported by the Materials Science Research Centre, Royal College of Art.

# A Social Practice Theory analysis of the impact of clothing fit on the use phase

**Clare Richardson[a], Rosy Boardman[a], and Simeon Gill[a]**
a) The University of Manchester, Manchester, UK

**Keywords**: Garment fit; Use-phase; Object Interviews; Social Practice Theory; Sustainable fashion; Slow fashion.

**Abstract**: Garment fitting processes in mass-produced fashion are inherently flawed, leading to widespread difficulty among consumers in finding well-fitted clothing. Previous studies indicate that the quality of clothing fit has a prominent impact on the length of garment use, with poor fit encouraging premature disposal. Thus, improved sustainability in fashion through slowed consumption and disposal is impossible without improved clothing fit. However, there has yet to be an in-depth study regarding how and why poor quality of clothing fit plays such a seemingly vital role in the use-phase of clothing. This paper uses qualitative object interviews through a Social Practice Theory lens to research this phenomenon. Findings indicate that emotional bonds are more frequently cultivated between wearer and garment when the garment in question is deemed to fit well, due to a pleasant wear experience encouraging regular wear. Such pleasant and regular wear facilitates emotional bonding through cultivation of memories and psychological comfort, encouraging longer use-phases.

## Introduction

Slow fashion refers to the production of timeless and durable products encouraging lower consumption and extended use (Fletcher, 2015; Gomes de Oliveira et al., 2022). Decreased production and consumption, and increased longevity of wear, is vital in reducing the environmental impact of the fashion industry (Wiedemann et al., 2020; Wren, 2022). Thus, changes in behaviour in the use-phase are required.

While participants frequently show interest in reduced consumption and increased use phases (Niinimäki & Hassi, 2011), there has been little mainstream movement towards, and inadequate study of such behaviours (Cairns et al., 2021; Liu et al., 2022; Wren, 2022). While limited, among existing studies there is a consistent reference to poor quality clothing fit encouraging premature disposal, and good quality clothing fit facilitating person-product attachment (Laitala & Klepp, 2015; Niinimäki, 2017; Niinimäki & Armstrong, 2013). This suggests the volume of fit failure experienced by mass-manufactured fashion consumers (Kasambala et al., 2016) to be a barrier to the uptake of slower use-practices. This study builds on prior literature, using semi-structure object interviews to understand rather than simply observe the suggested impact of clothing fit on the length and regularity of garment use. This will give an explorative indication as to the impact the current inadequacy of industry fit practices is having on the sustainability of clothing in the use phase.

This paper contributes to literature on sustainability in the use phase through an explorative investigation of an observed barrier to uptake of slow fashion behaviour. By using Social Practice Theory, the impact of quality of clothing fit on the social practices the garment forms part of is investigated, giving insight into the impact of quality of clothing fit on the sustainability of clothing use.

## Literature Review

### *Literature review of slow fashion*

The current mainstream fashion industry is built on the concept of continuous disposal of the old and consumption of the new (Kozlowski et al., 2012). For example, the Atlantic reports that 41% of US 18-24 year olds feel pressure to wear a different outfit every time they go out (Monroe, 2021), and iNews states that an estimated £140 million of wearable clothes are disposed of each year in the UK (Morris, 2022). The environmental impact of this approach to clothing production and consumption is staggering, contributing to issues such as excessive water usage (Grabish, 1999), textile dumps predominantly in the Global South (Beall, 2020), and the use of finite fossil fuel resources for the increasing production of synthetic fabrics (Nguyen, 2021).

Slow fashion is an alternative business model built on timelessness and durability, intended to encourage limited conscious consumption and extended use-periods (Gomes de Oliveira et al., 2022). While playing a vital role in reducing fashion's environmental impact (Wren, 2022), meaningful examples of slow fashion in literature and industry are scarce (Domingos et al., 2022). This is partially due to the current structure of the fashion industry relying on exponential growth, making anti-consumption an unconventional method of reducing environmental impact (Bardey et al., 2021; Kozlowski et al., 2012). Further, a reliance on change in consumer behaviour makes slow initiatives more complex to develop than green manufacturing and materials (Karell & Niinimäki, 2020).

There is a common problematic assumption that more durable materials result in more durable product-person relationships, a blatant misunderstanding of the complexity of person-garment interactions (Whitson-Smith, 2018; Woodward, 2014). While a growing number of scholars stress the importance of clothing's role in social practices when discussing slow fashion (Errázuriz & Müller, 2022; Fletcher, 2015; Joanes et al., 2020), very little attention is given to understanding this role. A literature review conducted by Domingos et al. (2022) found not only a lack of literature on slow fashion, but an even bigger lack of research focusing on consumer and user behaviour. Those that do, tend to rely on surveys and questionnaires. This is problematic due to a frequent observation of the intention behaviour gap (Cairns et al., 2021). This is the observation that fashion consumers will often claim intention to act, or believe they did act, in a more sustainable manner than in reality. This is seemingly true of slow fashion research, with Joanes et al. (2020) finding reported intention to reduce clothing consumption in surveys to bare no relevance to actual consumption reduction in diary studies. This highlights the complexity of the reality of consumption reduction in clothing, resulting in calls for explorative slow fashion research (Fletcher, 2015; Joanes et al., 2020).

### *Literature review of clothing fit and the use phase*

Despite the limitations discussed regarding surveys and questionnaires, they are a useful foundation, providing an indication as to what garment attributes and social practices require further study in the context of slow fashion. Among relevant studies, clothing fit is consistently cited as an important garment attribute regarding extended use and delayed disposal. Among Niinimäki and Armstrong's (2013) respondents to an open-ended questionnaire, the top two most cited physical attributes relating to garment attachment are comfort and good fit. In Niinimäki's (2017) later study, 85% of female participants cite clothing fit as important in garment attachment, supporting Niinimäki and Armstrong's (2013) findings. Whitson-Smith's (2018) wardrobe studies concur with this, finding comfort and good fit to be the predominant factors motivating prolonged wear. Further, in Laitala and Klepp's (2015) study of reasons for disposal in Norwegian households, clothing fit is cited as the second most common driver, after changes in the garment. While these studies observe a link between good clothing fit and the reflection of slow fashion behaviours, there is a gap in literature in the understanding of how and why clothing fit has such an impact on clothing use practices (Whitson-Smith, 2018), which may aid in its utilisation in the encouragement of more environmentally desirable behaviours. This research aims to fill that gap, aligning with Errázuriz and Müller's (2022) calls for qualitative research into facilitating factors of more sustainable clothing use practices.

## Social Practice Theory

Nairn and Spotswood (2015) refer to Social Practice Theory as directing the spotlight away from the individual or the culture, instead focusing on the reproduction of social practices. The present study investigates not the individual or the garment, but the reproduction of related social practices, to understand the role clothing fit plays in their formulation and how this impacts length and regularity of use. The importance of this approach to understanding sustainability in clothing use is exemplified by Joanes et al. (2020). They find that reported intention to reduce consumption in surveys bares no relevance to actual reductions in consumption reported in diary studies. This suggests the structure of social practices, rather than lack of interest, to be a barrier to implementing intended slow behavior. This indicates the need for study of social practices as opposed to individual opinion and intention when understanding drivers and barriers to slow fashion behaviour.

## Methodology

Qualitative semi-structured object interviews are carried out with a convenience sample of 13 UK women between the ages of 23 and 61. This is reflective of sample sizes in previous studies (Maguire & Fahy, 2021; Woodward & Greasley, 2015), and echoes calls for deep rather than broad research in understanding sustainability in everyday life (Kaufman et al., 2021) and the impact of clothing fit (Whitson-Smith, 2018). Clothing use practices are complex and somewhat unique to an individual (Gwilt, 2021), meaning they cannot be fully understood by generalisation, requiring in-depth qualitative exploration (Errázuriz & Müller, 2022).

During semi-structured interviews, participants are asked to try on two garments they deem to fit them well, and two they deem to fit them poorly, and discuss their use practices and emotional and physical responses. Such use of object elicitation is suggested to draw out more vivid and accurate discussion of clothing use (Woodward, 2015). This will provide deeper insights into the comparative use practices of well and poorly fitted garments and their drivers. Interview transcripts are analysed through thematic analysis.

## Findings

Concurring with previous literature, the well fitted clothing discussed by participants generally has longer and more frequent use than poorly fitted clothing. Among participants, long and regular use is driven by a pleasurable wear experience facilitated in part by good fit. A pleasurable wear experience results in the regular wear of garments, reinforcing pleasure in wear through the cultivation of attached memories, psychological comfort, and an emotional bond.

### *Pleasant wear experience*

The pleasant wear experience participants describe when discussing well fitted clothing arises from both a physical and emotional response to the garment. Participants frequently express a sense of confidence relating to a positive self-perception.

Lilly: *'I feel confident […] I feel attractive'*

While well-fitted clothing is perceived as making the wearer feel *'attractive'* (Lilly), *'sexy* (Bella)*',* *'smart'* (Megan), and *'elegant'* (Abby), poorly fitted clothing is perceived as making the wearer look *'scruffy'* (Megan), *'frumpy'* (Jade) or *'big'* (Frances). This suggests that well-fitted clothing is important in representing the wearer in a way they deem appropriate and pleasing, and thus is important in feeling confident in multiple contexts.

Further, the increased comfort levels of well fitted clothing discussed by participant's leads to a more pleasant wear experience. Interestingly, there was little age disparity regarding the importance of comfort. Many participants discuss the capacity of poorly fitted and uncomfortable item to *'ruin the day'* (Jade), while a well-fitted and comfortable garment allows the participant to *'relax'* (Frances).

### *Regular wear*

A pleasant wear experience leads to the regular wear of well-fitted garments in comparison to poorly-fitted alternatives.

Abby: *'I wear it quite a lot. I wear it whether it's an occasion or not'*

Multiple participants refer to the importance of well-fitted clothing in a work-place environment. Well fitted clothing is viewed among participants as a vital component of confidence in important professional events.

Jade: *'It makes me feel smart, so I often choose this if I'm doing, like, a presentation. This is a good dress for that because it makes me feel more confident.'*

On the contrary, Kate would not wear a pair of poorly fitted trousers to a conference because they do not make her feel confident.

Similarly, feeling attractive and confident for social occasions is heavily linked to the more regular use of well-fitted clothing.

Frances: *'I'm happy to wear it again and again on an evening out because I just feel it really* *suits me. I really like wearing it cause I can feel it's flattering'*

The role that clothing plays in social practices in terms of looking appropriate and feeling confident and at ease leads to quality of fit having significant influence on how often and when a garment is worn by participants. If a participant feels comfortable and confident, the garment is more likely to become both an everyday staple and a reliable option for important events.

### *Memory cultivation and emotional bonding*

Increased regularity of wear leads to the cultivation of attached memories and an emotional bond, seemingly reinforcing a pleasurable wear experience and contributing to extended use-phases. Some participants refer to the memories of past positive experiences as enhancing confidence. For example, past positive outcomes at professional events drive Abby to continue to wear her well-fitted blazer. Similarly, memories of fun and successful dates result in Lilly feeling confident and at ease when wearing her well-fitted skirt and top, driving her to repeatedly wear them for similar occasions.

Further, the frequent wearing of well-fitted clothing can lead to a level of psychological comfort, with the garments becoming almost an extension of the self.

Kate: *'It just fits and I'm comfortable and it's like, a bit of me'*

Emotional bonding and attachment of memories have previously been cited as vital in extending ownership and length of use. Good clothing fit appears to facilitate this, by eliciting an emotional and physical response in participants that drives the regular wear that appears to lead to emotional bonding.

## Discussion

Previous studies find long use phases to be encouraged by the accumulation of memories and emotional attachment (Errázuriz & Müller, 2022; Niinimäki & Armstrong, 2013), something which is facilitated among participants by good fit through a pleasurable wear experience. Emotive factors relating to long use phases have previously been discussed to be difficult to facilitate through physical garment attributes due to their reliance on use-behaviour (Connell, 2010; Karell & Niinimäki, 2020). The present study of use-behaviour indicates that such person-garment relationships can be facilitated by understanding what garment attributes encourage regular wear. According to Mugge et al. (2005) and Errázuriz and Müller (2022), emotional bonds between person and product can be created and maintained through regular use. Therefore, the encouragement of regular garment use through pleasing physical qualities, in this case clothing fit quality, has potential to facilitate emotional bonding and memory cultivation and thus an extended use-phase. This expands on Niinimäki's (2017) observation of the importance of clothing fit in garment attachment.

Findings indicate that participants are inclined to wear well-fitted clothing more regularly as a well-fitted outfit is vital in achieving a perceived positive presentation of the self. This desire to wear appears to be sustained over time by the development of emotional attachments, culminating in not only regular, but long and regular use. Feeling comfortable and believing oneself to look pleasing and appropriate instils a sense of confidence in participants, resulting in a positive wear experience and the accumulation of pleasant associations and memories. This further reinforces the positive wear experience, culminating in a cycle of long and regular garment use and thus the reflection of slow and more sustainable behaviours.

This indicates that improvements in garment fit have potential to facilitate more sustainable person-garment relationships by increasing pleasure in wear, thus encouraging regular wear and resulting in long use phases due to the accumulation of memories and positive associations.

## Conclusion

This study provides novel explorative insight into the importance of clothing fit on the social practices of garment use and the reasons for its observed impact on longevity of garment use. Findings conclude that the pleasurable wear experience that has previously been cited as vital in use-longevity can be facilitated through improved clothing fit due to its capacity to elicit a positive self-perception, sense of confidence, and comfort. This indicates that improved clothing fit may have potential in encouraging longer use-phases and contribute toward more sustainable clothing behaviours.

# Potential Rebound Effects of 1.5° Lifestyles

**Jessika Luth Richter[(a)], Oksana Mont[(a)], Andrius Plepys[(a)], Matthias Lehner[(a]**
a) International Institute for Industrial Environmental Economics, Lund University, Lund, Sweden

**Keywords**: Rebound effect; Spillover effect; Behaviour;Llifestyles.

**Abstract**: Understanding how lifestyles should and could change to meet the terms of the Paris Agreement is the aim of the project 'EU 1.5° Lifestyles'. It focuses on lifestyle options compatible with a 1.5°C target and explores the structural barriers and enablers to implementing these. Many of these lifestyle options relate to circular strategies such as sharing, reusing and repairing products. However, even if lifestyle changes are achieved, there is a risk of rebound and negative side effects that can undermine the intended outcomes. While rebound effects have been studied, particularly regarding energy and economic mechanisms, less attention was paid to other environmental effects and social mechanisms. A systematic literature review was conducted for rebound effects of sustainable lifestyles more generally and more specifically in the consumption domains: nutrition, housing, mobility, and leisure. This contribution maps the potential rebound effects of lifestyle changes and the different mechanisms by which these effects occur. It gives an overview of the literature on rebound effects related to sustainable lifestyle strategies for households. The results indicate some domain areas are more studied than others, but also a gap in understanding rebound effects empirically and holistically.

## Introduction

There is broad agreement that lifestyles changes are needed to meet the terms of the Paris Agreement (Akenji et al., 2021). Many of these lifestyle options relate to circular strategies such as sharing, reusing and repairing products. However, even if lifestyle changes are achieved, there is a risk of rebound effects that can undermine the intended outcomes (Koide et al., 2019). Understanding of rebound effects related to lifestyle changes, their possible mechanisms, and ways to address them is key to realising the full potential of behavioural change mitigation strategies.

## Research Approach and Method

The objective of this research was to understand how rebound effects have been studied in relation to sustainable lifestyles.

A structured literature review was conducted first for research on rebounds (searching the Scopus database for titles and key words for "rebound effect" + "sustainable" + "household OR individual" + "lifestyle". In addition, specific searches for rebound and particular lifestyle changes were also conducted. This yielded 108 articles. The abstracts of these were reviewed for relevance, yielding 82 articles. These articles were read and coded for types of rebounds, magnitude, domain of consumption, specific lifestyle options considered and measures to address rebound effects. In addition, 28 more articles were added through snowballing. This paper focuses on the studies that categorised rebound, measured its magnitude in key consumption domains and/or suggested strategies to mitigate rebound.

## Rebound Effects

There was a variety of different categorisations of rebound effects related to lifestyles in the literature. Here we give an overview of the main mechanisms and types of rebounds.

### *Economic mechanisms*

*Direct rebound effects* typically relate to an increase in demand for or usage of a product or service, which could be induced by improved material, energy or production efficiency, which in turn can lower the life cycle costs of products. For example, a consumer installing energy-saving lamps at home, however, then they might use them more intensively or buy and install more lamps than they had before, which would undermine the energy savings.

*Indirect rebound effects* most often refer to a secondary effect from re-spending of monetary savings towards the consumption of other goods and services, with an associated environmental impact (Gillingham et al., 2016). For example, a consumer may change to more energy-saving lamps and use the savings for consumption of another good or service, with its associated environmental impact, e.g. a vacation ("lights to flights" - see Chitnis et al., 2013). The economic savings is often referred to as the "income effect" while there is also a "substitution effect" in that there will be relatively less expenditure on lighting and more on another good or service (Reimers et al., 2021). In addition, increased efficiency, savings, and changes in demand can lead to economy-wide effects, i.e. lower costs lead to additional output (Jenkins et al., 2011).

### *Psychological mechanisms*

There are also studies exploring psychological mechanisms of rebound effects. An important theory is moral licensing, essentially that after doing a good deed (moral action), e.g. buying a more efficient product or reducing consumption in one area, an individual may feel they can then compensate with a less good or even "bad" behaviour or action (Bauer & Menrad, 2020; Burger et al., 2022). While the subsequent behaviour is the same as in the examples of economic rebound, the mechanism is different.

Whether moral licensing occurs is also related to moral consistency and moral balancing (Cornelissen et al., 2013). Moral balancing is when people consider trade-offs and consequences while moral consistency is when people are guided by rules and integrity. The former is associated with moral licensing while the latter generally inhibits it for individuals with strong environmental values and a rule-based mindset, e.g., see Bauer & Menrad (2020).

Adding to the complexity, the triggering behaviour itself can influence subsequent behaviour. This is often referred to as a 'spillover effect'". After making one behaviour change, a person might make similar changes in the same or other domains (Seebauer, 2018). Bauer and Menard (2020) found that this is only the case for individuals with environmental values guided by rules.

### *Other rebound effects*

Rebound effects can be studied not just in how consumers spend money, but also on what consumption activities they choose to spend their available time (Jalas, 2002). Time use rebound research shows that increasing efficiencies and speeds of transport have enabled longer distances and increased travel overall (Font Vivanco et al., 2022; S. Kim et al., 2020). Studies have also focussed on the environmental impacts of activities and how changing allocation of time use for different consumption activities can change overall environmental impacts (Bieser & Hilty, 2020).

Hertwich (2005) argues that the focus in research on economic rebound effects is too narrow and that any analysis of rebounds should be extended to both behavioural and systems responses. While these effects may be unintended, they are not always negative (for example, positive health effects). The term ´ripple effects´ is suggested for conceptualising rebound effects more broadly.

## Lifestyle Rebounds

Here we focus on the specific rebounds from studies specific to lifestyle domains.

### *Transport*

Many studies on rebound effects examined ridesharing/carpool and car sharing services. Coulombel et al. (2019) argue that the savings from sharing costs can induce fewer vehicles and less congestion; which, in turn, can cause more use of car transport and driving longer distances. The authors estimate size of the rebound effect is between 68% and 77% in terms of GHG reductions, in line with earlier research (Shaheen et al., 2016; Xu et al., 2015)

Rebound estimates for carsharing vary significantly. (Chen & Kockelman, 2016)found rebound effects of just 2%, Vélez (2023) found as high as 70%- 85%, and Font Vivanco et al. Font Vivanco et al., 2015) found between 40% in the EU, They find an indirect environmental rebound effect of 135% due to re-spending with higher environmental intensities (e.g. flying). This is in line with earlier studies (Hertwich, 2005; Briceno et al., 2005))

Ottelin et al. (2017) found reducing driving results in a rebound between 11-41%, with an average of 23% (in line with Chitnis et al., 2014; Druckman et al., 2011). The same study estimates even higher rebound effects (68%) for an average middle-income Finnish person who gives up a car (Ottelin et al., 2017). It is assumed that savings are re-spent on average consumption and that other travel, in particular flying, is a large driver of rebound. Similarly, Vita et al. (2019) find if savings from cycling re-spent on flying offset the emissions saved.

Teleworking can potentially reduce commutes and distances travelled (Caldarola & Sorrell, 2022; Shabanpour et al., 2018); however, a growing number of studies show that telework may encourage longer distances from work if people do not need to commute to work every day ((Cerqueira et al., 2020; de Vos et al., 2018; Zhu, 2012). People may switch to teleworking, but also shift to less sustainable transport modes (Ceccato et al., 2022; Hensher et al., 2021). In addition, the energy efficiency of workplaces versus homes affects the total impacts and rebounds from teleworking (Guerin, 2021). Teleworkers may also have more non-work-related travel (de Abreu e Silva & Melo, 2018) and families with at least one teleworker tended to travel more per week (Caldarola & Sorrell, 2022; Kim et al., 2015).

### *Housing*

Chitnis et al (2013) estimated the rebound effect connected to reducing indoor temperatures 1 degree C to be only 7% while other heating and energy efficiency measures resulted in a rebound of around 12-13%. They found even higher effects if the embodied energy of the efficient technologies is also considered (e.g. up to 67% for solar thermal). Bardsley et al. (2019) found a direct rebound effect up to 40% with thermal upgrades to housing in the UK.

In terms of households adopting renewable energy such as solar photovoltaics, several studies have estimated rebound effects: 5-8% in California, USA ((Kim & Trevena, 2021); 7% in Dutch households (Aydın et al., 2023); 5-33% in Germany (feed-in tariffs were associated with higher rebound – see Galvin et al., 2022), 15%-20% in Australian households (see (Deng & Newton, 2017). Galvin et al. (2022) in particular note that policies like feed-in-tariffs can undermine their own goals through rebound.

Sorrell et al. (2020) note the high potential for rebounds in response to energy sufficiency related behaviour changes. In particular, Große et al. (2019) also find flying as a potential rebound action associated with urban and smaller living spaces.

### *Food*

Reducing food waste has potential for a significant rebound effect, with the magnitude differing in studies; e.g., 57% (Hagedorn and Wilts, 2019), 77% (Chitnis et.al., 2014), 23%-59% (Salemdeeb et al., 2017) and 68%-100% (Bjelle et al., 2018). Again, assumptions about re-spending are key. If savings from avoidance of food waste go into energy-intensive categories, such as air travel and heating of space, the environmental benefits of avoiding food waste can be completely negated (Martinez-Sanchez et al., 2016). WRAP (2014), however, observe that when avoiding food waste people often purchase food of higher quality and cost, such as buying local food, better quality meat or switching to higher-cost food categories.

Reducing meat consumption at home (50%) and in restaurants could result in a 25% rebound effect ((Wood et al., 2018). These rebound effects were caused by the increased demand for non-meat products and increased consumption of other products triggered by savings from the no-meat diet. A study of vegetarianism by Grabs (2015) shows significant rebound effects: 76-130% for energy use and 25-88% for greenhouse gas (GHG) emissions. They indicate that higher-income groups show lower rebound effects and lower-income groups have higher rebound effects because they tend to spend savings on more environmentally intensive goods.

An interview study by Dreijerink et al. (2021) explored awareness about the moral licensing effects of Dutch consumers who already follow a vegetarian diet. 5 out of 26 interviewed consumers demonstrated moral licensing behaviour, ranging from eating meat after several days of following a vegetarian diet (direct rebound) to having fewer hesitations when considering buying a less fuel-efficient car (indirect rebound).

Challenging previous studies, Andersson & Nässén (2023) show that a vegan diet has a positive spill-over effect on other consumption domains, reducing overall impacts. This is explained by vegans having pro-environmental values that prevent them from re-spending in categories with high environmental impacts. Lower rebound is also supported by an earlier study where 'green' consumers were assumed to re-spend on organic products (Carlsson-Kanyama et al., 2005).

According to Bjelle et.al. (2018), eating an organic green diet leads to between -47% and -68% rebound effects. When other measures are added, such as local products and composting, the negative rebound effects increase to -91%-134%, due to the high costs of implementing both of these actions.

### *Leisure and Goods*

The rebound effect studies of transport for holidays and leisure largely overlapped with the transport studies already mentioned. Carlsson Kanyama et al., 2021 specifically consider train holidays, versus driving, flying or staycations. The choices results in a shift in GHG effects, but the savings, or lack thereof, depend on the assumptions made.

Wood et al. (2018)) investigate reductions in demand for apparel and textiles and found a high (75%) rebound due to the low carbon intensity of the clothing sector compared to other consumption categories to which consumption shifted. On the other hand, Kawajiri et al. ( 2015) explicitly refer to buying higher quality and more expensive goods such as clothing could actually reduce both climate impacts and decrease rebound effects.

Makov & Font Vivanco (2018) looked at the rebound effects of smartphone reuse, finding a range of effects between 27-46%, with an average of 29%. The rebound effect is mainly from the re-spending of savings (mostly on food, non-durable goods and transport) and the authors note that the relatively low GHG savings from purchasing a secondhand phone versus alternatives also results in a rebound from imperfect substitution. The authors also find the reuse is not a direct substitute for buying new, which was also a finding of Ottelin et al. (2017), who also found repairing associated with an increased material footprint.

## Measures for Avoiding Rebound

It is important to note that rebound effects are also associated with development and wellbeing (Makov & Font Vivanco, 2018). Lower income households may not be consuming at levels desirable for their wellbeing. For example, heating can be associated with positive health impacts from allowing energy-poor households to heat to their preferred temperature (Seebauer, 2018). In addition, some of the highest rebound effects for energy efficiency lighting and solar PV, e.g. up to 200% in India (see Chakravarty & Roy, 2021) are associated with meeting unmet demand as households have increased access to services and technologies. It is suggested that rebound measures should first and foremost target high income households (Murray, 2013).

The more general suggestions for addressing rebound effects in the literature varied. Seebauer (2018) found that higher education levels reduces rebounds and suggest education helps individuals better understand aims, e.g. of renovations and their own impact.

How savings are re-spent is also key to limiting rebound. As much as possible, savings should be directed towards low-impact categories such as health, education and cultural activities and these consumption categories also have positive social impacts (Albizzati et al., 2022).

Wiedenhofer et al. (2018) considered that income remains a driver of overall carbon footprints and that less work with less income can reduce carbon footprints and rebounds due to reduced spending and shifts in consumption patterns. The authors suggest more time could be spend on lower carbon well-being activities such as care and community activities.

There are also specific suggestions to avoid rebound effects in the consumption areas. In transport, these include improving public transport, reducing road capacity, and increasing the cost of travelling by car solo (Coulombel et al., 2019). In the food domain, organic food is often mentioned as an example of a re-spending category of goods that helps avoid rebound effects due to higher prices of organic products (Hertwich, 2005). When efficiency measures lead to cost savings, the savings should be spent on higher-quality goods with lower sustainability impacts.

Claudelin et al. (2020) find that reinvesting saved money from one low carbon lifestyle change (e.g. reduction of meat or flights) into a low-carbon investment (e.g. a solar energy or carbon sequestration project – i.e. "impact investing") can be an effective measure to reduce rebound. It has the added benefit of increasing the GHG mitigation potential of the first action (e.g. a negative rebound effect).

## Broadening Rebound Research

Our systematic literature review revealed that rebound effects related to sustainable lifestyles have been primarily studied by examining economic mechanisms, associated with savings, income, spending. Studies have been mostly quantitative (Figge & Thorpe, 2019) and focussed in the energy domain (Reimers et al., 2021; Vita et al., 2019; Wood et al., 2018).

The narrow conceptualisation of rebound effects so far does not address the complexity of consequences of low-carbon behaviour changes (cf. Font Vivanco et al., 2022). However, a broadening of the conceptualisation of rebound effects also results in boundaries of the concept becoming less defined.

Echoing Castro et al., (2022)'s findings of rebound effects of the circular economy we also find a need to further study the human behaviour aspects of rebound effects. Some studies, e.g. Andersson & Nässén (2023) find strong environmental awareness and attitudes result in spillover rather than rebound effects; however, the conditions and generalisability for this are not clear (see e.g. Sorrell, 2018) and should be explored further. Both broad consideration of rebound effects as well as a focus on empirical studies should be part of a future research agenda.

## Acknowledgments

This research was supported by funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101003880.

# Practices of Motherhood: Embodied Experiences of Everyday Fashion

**Emma Rigby**[a], **Anja Connor-Crabb**[b],
a) Cardiff Metropolitan University, Cardiff, UK
b) University of Leeds, Leeds, UK

**Keywords**: Motherhood; Clothing; Use; Durability; Change.

**Abstract**: Practices of garment use and care are pivotal to sustainability in fashion (Fletcher, 2016; Laitala & Klepp, 2020). This research focuses on working mothers with young children: how the dual pressures of parenting and work influence changes in clothing practices. The project builds discussion about the feminization of care, how care can transform relationships with fashion, and how these ideas link to sustainability (Southwell, 2014; Fletcher & Tham, 2019). The intersection of care and motherhood is significant because it marks a time of change for women and forms the context within which the next generation grows up. The constraints posed by modern-day parenting often prevent women from acting upon concerns for the environment reflected in their garment practices and their ability to model pro-environmental behavior for their children. This exploratory qualitative study draws on findings from garment-led interviews (Twigger Holroyd, 2017) with 20 working mothers of young children in the UK to show how evolving household dynamics prompt changes in garment use. The findings present an entangled picture of the cultural, social and emotional landscape of early motherhood, evidencing the undeniable materiality of fashion embodied in the experiences of becoming and being a mother. Three key themes that emerged from the research in relation to change include: comfort and movement, identity, and enduring style.

## Introduction

Within the field of fashion and sustainability, there is an established body of research that recognizes the significance of garment use practices to facilitate longer active garment lifetimes (Fletcher, 2016; Laitalia & Klepp, 2020). Wearing existing garments for longer can reduce the need for new garments, thus slowing the speed of material throughput and resource use (Laitala & Klepp, 2015; WRAP, 2017).

Building on this logic, we focus on early motherhood as a liminal period where clothing practices evolve and develop in new ways. Indeed, the early years of motherhood are often chaotic, unpredictable and tiresome, and many aspects of everyday life change. The aim of the research is to better understand factors that contribute to change in clothing practices during this period and consider opportunities for the adoption of more sustainable clothing practices. We do this through exploring the experiences and practices of 20 working mothers with young children in relation to specific garments owned by the participants. Data is collected through the exploratory method of garment-based interviews (Twigger Holroyd, 2017).

## Context

### *Motherhood*

In the broader scope of this project, we understand motherhood as a non-binary and inclusive term relevant to all those who have experienced and participated in care giving. We use the term motherhood rather than parenthood because motherhood is a term more culturally entrenched with practices of care (Collins, 2019).

Literature surrounding both care and motherhood, specifically within the area of gender feminism, has long criticized how care and motherhood are feminized and simultaneously devalued (e.g., Millar Fischer & Winick, 2021; Tronto, 2005). Working mothers often carry a dual load: holding down employment while taking on the dominant share of parenting, often in combination with housework (Collins, 2019; Friedmann, 2019).

Existing literature explores how motherhood is socially constructed and how different pressures act on women to perform the role of "mother", but how women respond less so. In this research we look at how women use clothing as part of the material culture of motherhood, how change is assimilated through clothing, and how this links to consumption, use and durability.

### *Consumption*

Consumption and durability share an inherent relationship framed by the use of products and related human behaviors. Prioritizing the use of products and appliances within studies of sustainable consumption is recognized as a logical path to better understand how and why different forms of environmentally damaging consumption occur as they do (Shove & Warde, 1998). Consumption is an outcome of how particular practices are played out (Warde, 2005).

### *Continuity and change*

In the past decade, continuity and change have been popular areas of focus within studies of sustainable consumption (Shove, Pantzar & Watson, 2012). It is recognized that changes in life circumstances (e.g., finding a partner, having a child, starting a new job) often provoke changes in routines and habits (Verplanken, 2006). Some research has looked at how moments of change become intervention points that disrupt existing routines and prompt pro-environmental changes in practices (Burningham et al., 2014; Jack, 2014).

Skjold (2016) explains changes in dress practices and taste preferences through outlining the Biographical Wardrobe Model. She explains the concept of *continuity* to highlight how change occurs gradually in tandem with external life-altering events (e.g., teenage "identity crisis", starting a new job, finding a partner, having children). Skjold (2016) found people's wardrobe items act as anchors to connect their identities of the past, present and future. Repetition of shape, style and fabric connect gradual changes in preferences of taste throughout different phases of life. This method of wardrobe research contrasts with other methods of understanding dress practices that prioritize newness and trends; it opens a space to better understand the everyday decisions people make as they dress and how these decisions are influenced by temporality. Similarly, Woodward's (2007) research shows that decisions on what to wear are deeply influenced by how people develop social constructions of their identity. Clothes kept and worn for the longest provide greater value during identity construction during different life stages.

Other research which has looked at clothing use specifically during pregnancy. Ogle, Tyner and Schofield-Tomschin (2013) found maternity clothing disrupts existing identities, affirms new identity as "pregnant/expectant mother", and at the same time supports the continuity of existing identity. Maternity clothing incited and relieved ambivalence during this significant life change to motherhood. Research that looked at how women's everyday shopping practices change in the first few months following the birth of a child (Burningham et al., 2014) found that change is not instantaneous but rather primarily gradual, ongoing, and oftentimes transient. Further, the research recognized the significance of other people in the household (young families do not act in isolation) and how they influence change.

### *Durability*

Increasing product durability is widely understood as a method to increase a product's useful and active life (Cooper et al., 2013; WRAP 2017). Doing so is assumed to reduce the need for further acquisition-driven consumption (Chapman, 2009). Within fashion design and sustainability literature, usership and human action is recognized as an intrinsic component fostering garment durability (Fletcher, 2012; 2017). Delving deeper, more recent research on "decentering durability" (Fletcher & Fitzpatrick, 2021) highlights the need to reframe our understanding of durability outside of the common Western epistemologies as implicated in the environmental crisis. Here, an understanding of durability is offered through plural ideas and actions. Fletcher and Fitzpatrick (2021) have identified features of durability as defined by a) community and how the culture of the community projects durability; b) gender and the intersections of cultural and personal expectation; c) care and decentralizing care-based knowledge from industry to home; d) body and how it changes and feels in different clothes; e) temporalities and how time alters relationships with garments; f) emotions and how they are socially and culturally specific and how they contribute to individual accounts of durability; g) and practical action and agency where durability is linked to independent action and practical skill. These descriptors are relevant to our project, which recognizes the complex social context in which fashion and clothing behaviors exist (Fletcher, 2016).

### *Summary*

In summary, there is a lack of critical design research concerning motherhood, the material culture that surrounds it and implications for how garments are used. Throughout motherhood, many changes are negotiated which are reflected in evolving consumption and use practices (Burningham et al., 2014; Ogle, Tyner & Schofield-Tomschin, 2013). As such, this project contributes to and expands the existing bodies of research concerning clothing practices (e.g., Buckley & Clarke, 2012; Connor-Crabb & Rigby, 2019; Fletcher, 2012; Laitala & Klepp, 2020) with special focus on motherhood, change and how these ideas link to sustainability (Fletcher & Tham, 2019; Southwell, 2014).

## Methods

Fieldwork was conducted between May and August 2021 with 20 working mothers (age 29 to 45) of young children (age 2 months to 6 years) residing in various UK locations. Semi-structured garment-based interviews were carried out online using Zoom, audio recorded and subsequently transcribed verbatim using Otter.ai software and thematically coded using QSR NVivo software.

The aim of the interviews was to identify factors that contribute to changes in the way clothes are worn and used during early motherhood. To explore this, we asked participants as a discussion prompt (Twigger Holroyd, 2017) to select an item of clothing that signifies change since having children. This approach builds insights from individual experiences of motherhood, tapping into accounts from a societal group that is widely underrepresented and undervalued. Millar Fischer and Winick (2021, p.16) recognize this approach as “explicitly feminist and antiracist”.

Although we do not view motherhood as exclusive to cis women who have borne children, our small demographic sample for this project does not reflect the diversity of all those who experience motherhood. Participants recruited through our personal networks and snowballing did not lead us to any participants outside of this identity; we acknowledge this to be a limitation of the study.

## Results and Discussion

The changes to the household dynamics when a child is born are significant and are consequently reflected in clothing practices of acquisition, use and care.

### *Comfort and movement*

An immediate and obvious theme emerging from the interviews was the need for comfort and styles that allowed for movement. Participants described how their bodies physically changed through losing and gaining weight, as well as simply feeling different postpartum.
Pre-pregnancy items no longer fit or they felt too restrictive with the physical demands of looking after children. Participant A6 describes the garment shown in Figure 1:

> And it's comfortable enough again that I can crawl around the floor. So I feel like skirts and dresses went out the window for a while. Especially when with a really little one because you’re kind of on the floor playing.

**Figure 1. Garment for movement (A6).**

The chosen items were typically newly purchased to accommodate the need for increased movement and comfort. They are either stretchy or more loose-fitting for "more breathing room" (A8) and often become intensively used items, as exemplified by a participant who described her leggings, pictured in Figure 2 as "a safety comfort uniform" (E7).

**Figure 2. A safety comfort uniform (E7).**

Women who breastfed discussed the significance of accessibility in dictating what they were able to wear. Tops with concealed openings allow for modest access, while integrated bras would allow for fluctuations in bra size (see Figure 3). Changes in body shape and size can lead to some wardrobe items becoming redundant, at least temporarily. Hence, evolving relationships with our bodies can impact garment longevity–these changes are "personal, gendered and shaped by cultural values and beliefs" (Fletcher & Fitzpatrick, 2021, p. 15).

**Figure 3. Top with integrated bra (A2).**

*Identity*

The wardrobe becomes a space where identities of past, present and future are connected (Skjold, 2016) when women negotiate clothing as expressions of identify in addition to functional requirements. Participant A2 reports:

> I didn't feel like I could dress how I wanted to, because of the change in body size and the change in body shape as well […] it was maybe by four or five months old that I remember turning to my mom and saying, *I feel like I'm dressed like me.* [...] I feel like I've styled myself. Yeah. That there was a choice.

The desire to express style authentically, rather than conforming to trends, has generally led to purchasing new items less often than in younger years, which is also due in part to a change in priorities and lack of time. For instance, one participant said of her new cardigan (see Figure 4): "I'm going to dress for me now. […] So it was almost like the first step of recapturing and rediscovering me" (E4).

**Figure 4. Rediscovery of identity (E4).**

In some cases, this led to new purchases. Participant A8, for example, describes a bright pink and red striped jumper she bought inspired by her daughter's favorite color combination (see Figure 5):

> I remember the first time I put this on, and it felt really like a bold piece of clothing to wear. […] I think it was just I felt like a really different person having had Anya. […] I think it was more about trying to find something that really felt me

**Figure 5. Feels-like-me bold jumper (A8).**

### *Enduring styles*

Many women described spending more on an individual item for themselves that they would consider good quality and long-lasting (e.g., garment in Figure 6). This aligns with the connection Fletcher and Fitzpatrick (2021) describe between age and the acceptance of more durable clothing. This was motivated by sustainability concerns in some cases, though cost was a barrier. Second-hand garments enabled budget-friendly sustainable consumption. Most participants cited an increased desire to live sustainably since having children or linked to newly gained knowledge on the topic. Buying, and to a lesser extent selling, second-hand children's clothes – and thus increasing their lifespan – from online platforms or mobile phone apps was common, due to convenience, while visits to brick-and-mortar shops decreased significantly:

> Since having the kids, I don't really get to go around the charity shops or the car boots sales so much. And if I did, there was no hope in hell of me getting to try it on and check it even fits[...]. So I buy more stuff new, although I'm not buying very much stuff, there's more of a chance of it being new than there was. (E1)

**Figure 6. Good quality garment (A3).**

### *Summary*

Overall, themes relating to changing bodies and lifestyles and their impact on clothing choices emerged from the interviews. A shift in priorities expressed through a focus on more enduring styles was identified. Participants discussed environmental concerns in relation to their clothing choices and care practices; however, their ability to apply their values and intentions were often hindered by time pressures, particularly in relation to sourcing second-hand garments – a key strategy to increasing garment lifetimes (Gracey & Moon, 2012).

## Conclusion

In this paper we explored motherhood as a liminal space, where clothing practices evolve and develop in new ways. The findings present an entangled picture of the cultural, social and emotional landscape of early motherhood, evidencing the undeniable materiality of fashion embodied in the experiences of motherhood. Three themes that emerged from the research in relation to change include: comfort and movement, identity, and enduring style.

The experience of motherhood is closely intertwined with the physical demands on the body. Participants described a range of expected and unexpected ways in which the physical demands of motherhood influenced the types of clothes they wore. Negotiating identity in motherhood can lead to new purchases, motivated by an expression of their authentic self, as also found by Ogle, Tyner and Tomschin (2013) rather than the perceived need to follow trends. Garments will thus be in use longer. This builds on the work of Skjold (2016) and understanding of the "biographical wardrobe", where change takes place as a gradual process; it reflects repetition of the familiar regarding style, color, shape and fabric. Buying longer-lasting clothes and wardrobe staples of better quality had higher priority during motherhood. Generally, a desire for sustainable lifestyles but lack of time due to the dual pressure of parenting and work compromised the ability of participants to act fully on environmental concerns.

Building on existing scholarship (Collins, 2019; Millar Fischer & Winick, 2021), we argue that the feminization of motherhood left our participants increasingly time poor and had a negative impact on their ability to model pro-environmental behavior. Accordingly, we recognize that fashion and sustainability merge into a feminist issue. Potential areas for future research include identifying factors for a more balanced domestic load, particularly regarding clothing practices and how factors may vary in different geographical regions.

# Drivers and barriers for bio-based plastics in durable products

**Linda Ritzen, Puck Bos, Phil Brown, Ruud Balkenende, Conny Bakker**
Delft University of Technology, Delft, the Netherlands

**Keywords**: Bio-based plastics; Drivers; Barriers; Circular economy; Durable products; Value chain.

**Abstract**: Bio-based plastics are gaining attention as a sustainable, circular alternative to the current, petrochemical-based plastics. The main application of bio-based plastics is in single-use packaging with short lifetimes. Extending the application of bio-based plastics products towards durable consumer products requires the involvement of different value chain actors. An online interactive workshop, with 46 participants representing the entire value chain, produced a list of drivers for using bio-based plastics in durable consumer goods and barriers to overcome. The primary barriers to using bio-based plastics in durable products were related to their underdeveloped value chain and a need for more knowledge. The underdeveloped value chain was associated with high costs and no infrastructure for recovery at end-of-life, reducing potential environmental benefits. Participants indicated that they did not expect the value chain to mature without substantial government stimulations. Participants also noted a lack of knowledge among value chain actors as well as end-users. Value chain actors expressed that they need more clarity about what bio-based plastics are available and how they can be used in a sustainable way. While the market demand for sustainable alternatives is growing and bio-based plastics are a valuable marketing tool, users are poorly informed, and marketing should be thoughtful to avoid greenwashing.

## Introduction

Plastics are vital for modern life, but their environmental impact and damage caused by plastic pollution necessitate a new approach. Plastic production consumes up to 8% of fossil fuels extracted annually (Lambert & Wagner, 2017), while it is estimated that 79% of all plastic ever produced has accumulated in landfills and the natural environment (Geyer et al., 2017). Bio-based plastics have the potential to enable circularity since they are based (at least in part) on biomass, rather than finite petrochemical resources (International Standards Organisation (ISO), 2015). The renewable nature of bio-based plastics enables circularity at the plastic production level. While only accounting for 1% of all plastics produced in 2022, the market for bio-based plastics is growing at over three times the rate of that of petrochemical-based plastics (Skoczinski et al., 2023). The Circular Economy Action Plan contains plans to stimulate the bio-based sector (European Commission, 2020).

Bio-based plastics can be divided into drop-ins and dedicated bio-based plastics (Carus et al., 2017). Drop-in bio-based plastics are chemically identical to petrochemical-based plastics of the same name, such as polyethylene (PE). Dedicated bio-based plastics have no petrochemical-based equivalent. Biodegradable plastics are plastics that can be decomposed by living organisms and can be bio- or petrochemical-based. Not all bio-based plastics are biodegradable, although the two are often associated (Lambert & Wagner, 2017).

The main application of bio-based plastics is in single-use packaging with short lifetimes (Skoczinski et al., 2023). The application of plastics in single-use products will likely be limited by environmental legislation in the European Union (European Union, 2019) and other countries (Xanthos & Walker, 2017). The application of bio-based plastics may then shift towards durable products. However, applying bio-based plastics in products with extended lifetimes requires the involvement of value chain actors unfamiliar with these materials.

This study aims to unveil how bio-based plastics are perceived by actors throughout the value chain for durable consumer goods: in this case, the telecommunication sector. An interactive workshop produced a list of drivers for using bio-based plastics and barriers to overcome in order to extend the lifetime of bio-based plastic products from packaging towards durable consumer goods.

## Methodology

In October 2020, 46 participants representing the entire telecommunications value chain attended an online workshop. Participants were approached through the network of a Dutch telecommunications company and that of the authors. Prior to the workshop, 39 participants filled out a survey about their role in their company and their experience with bio-based plastics. Table 1 contains an overview of the participants. Survey participants covered the entire value chain of telecommunications products, in addition to the fields of legislation and research. 26 out of 39 respondents were employed in a sustainability-related role.

| Role | Number of responses |
|---:|---:|
| Design and/or development | 10 |
| Legislation | 4 |
| Management | 10 |
| Research | 5 |
| [illegible] | 8 |
| Sustainability | 26 |
| Other | 1 |

**Table 1. Overview of participants' role. Participants could select multiple answers.**

During the workshop, the participants were given a brief introduction to bio-based plastics, followed by an interactive assignment. Participants were asked to fill out an online collaborative whiteboard with drivers and barriers to using bio-based plastics in durable products. Participants could place green dots on entries to mark them as important.

After the workshop, all entries were anonymised, and those not phrased clearly were removed. The remaining entries were independently coded by two of the authors and grouped into drivers and barriers. These drivers and barriers were developed into themes that describe the participants' attitudes towards using bio-based plastics in their durable products. To determine the perceived importance of each driver or barrier, the number of post-its corresponding to them was combined with the number of green dots they received.

## Results

### *Prior knowledge of the participants*

Figure 1 displays the outcomes of the pre-workshop survey. The majority of respondents rated their knowledge about bio-based plastics as low to very low. Most also had little to no experience working with bio-based plastics. 8% of respondents were already producing products containing bio-based plastics, and 77% of respondents considered it likely to very likely that they would do so in the near future.

### *Drivers and barriers to bio-based plastics usage*

Drivers for bio-based plastics usage were categorised into the following seven themes: legislation, public perception, sustainability, design opportunities, sourcing, end-of-life, and collaboration. Below, the drivers for each theme are listed in order of perceived importance. It should be noted that the statements represent the participants' views and not necessarily the facts or the authors' views.

Driver theme 1: Legislation

- Existing and future regulations and sustainability targets could incentivise the use of bio-based plastics. For example, the European Green Deal, the Circular Economy Action plan, and $CO_2$ emission targets.

Driver theme 2: Public perception

- Bio-based plastics can be used as a marketing tool to engage customers who are becoming increasingly environmentally contentious.
- Being an early adopter of bio-based plastics will reflect well on a company's image and establish them as a frontrunner.
- The interest in bio-based plastics in the corporate world is growing.
- Policymakers are driven by increased public awareness of environmental issues as well as business needs.

Driver theme 3: Sustainability

- Bio-based plastics can help companies to realise a circular business model.
- Bio-based plastics production can have a lower environmental impact than petrochemical-based plastics production.
- Bio-based plastics can be a sustainable solution for the long term due to their renewable resources.

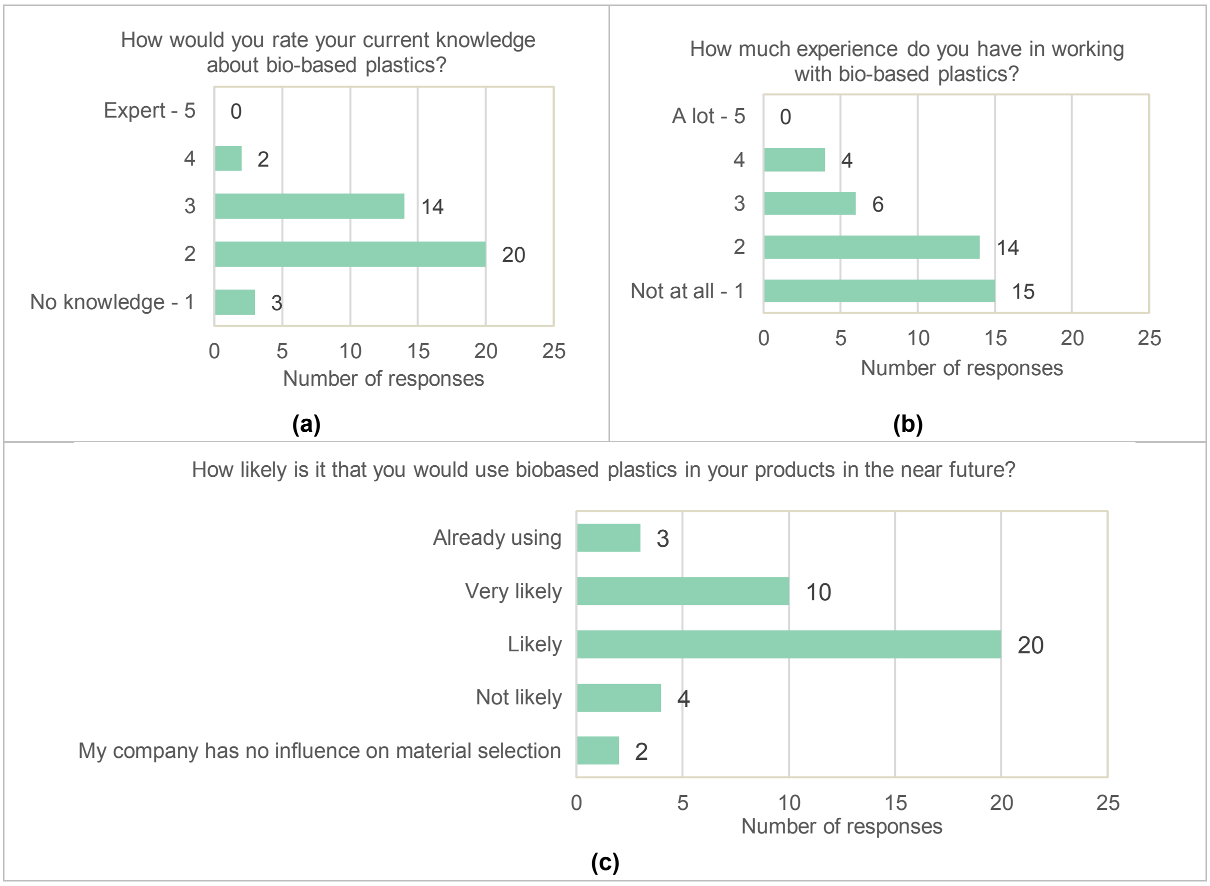

**Figure 1. Outcomes of the pre-workshop survey about (a) prior knowledge of bio-based plastics, (b) prior experience with bio-based plastics, and (c) likeliness of using bio-based plastics in the near future.**

Driver theme 4: Design opportunities

- Bio-based plastics can have new and unique properties that can be exploited in product design to add to performance and user value.
- Drop-in bio-based plastics can directly replace petrochemical-based counterparts, enabling a gradual transition.
- A new material creates the opportunity to experiment and develop new knowledge about its application.

Driver theme 5: Sourcing

- Bio-based plastics can be produced from a wide range of feedstocks, including waste, potentially resulting in a stable and local supply chain that is ultimately less dependent on fossil fuels.

Driver theme 6: End-of-Life

- Biodegradable (i.e. not per se bio-based) plastics can reduce waste and can be used to collect other compostable materials. For instance, biodegradable compost bags to collect home compost.
- Biodegradable plastics can provide a sustainable solution for products that wear or dissipate into the environment, such as tires or shoe soles.

Driver theme 7: Collaboration

- Being a new material, bio-based plastics allow for more interaction, knowledge sharing, and collaboration within value chains.
- Bio-based plastics can create new job opportunities.

Barriers to bio-based plastics usage could be categorised into the following seven themes: costs, lack of knowledge, sourcing, sustainability, end-of-life, an uncertain future and material properties. Below, the barriers for each theme are listed in order of perceived importance by the participants.

Barrier theme 1: Costs

- Bio-based plastics are more expensive than petrochemical-based plastics, increasing the price of a product.
- Users may not be able or willing to pay more.
- The entire value chain must change to accommodate bio-based plastics, which is expensive and time-consuming.

Barrier theme 2: Lack of knowledge

- Not all properties of new bio-based plastics are known. Bio-based plastics may have a lower technical performance than petrochemical-based plastics.
- Adding more variation in plastics adds complexity to proper disposal, making it confusing for end-users.
- It is risky to communicate bio-based with end-users because they do not have much knowledge about the concept, and the environmental benefits are still unclear.
- There are no clear guidelines on how to use bio-based plastics.
- Policy makers are not well informed about bio-based plastics.
- Bio-based plastics are not well known throughout the value chain. There is also insufficient information available.

Barrier theme 3: Sourcing

- Transitioning fully to bio-based plastics may not be possible without competing with food supply.
- The current volumes of available bio-based plastics are too low to cover demand and to enable recovery at end-of-life for dedicated bio-based plastics.
- Pollution from biomass may transfer into the plastic.

Barrier theme 4: Sustainability

- There are no standards for measuring and communicating the environmental impact of bio-based plastics and no policies regarding resource use, potentially leading to greenwashing.
- There is not enough clear information available about the environmental impact of bio-based plastics production and whether it is lower than petrochemical-based plastics.
- Marketing a product as more sustainable may cause end-users to adopt a less critical consumption attitude.
- Company image may suffer if bio-based plastics are derived from biomass that has damaging environmental effects.

Barrier theme 5: End-of-life

- Recovery of bio-based plastics at end-of-life is not yet guaranteed. Especially for dedicated bio-based plastics, production volumes are too small to facilitate reverse value chain infrastructure.
- The degradation levels of bio-based plastics compared to petrochemical-based plastics during recycling are unknown.
- Recyclability still needs to be guaranteed by product design.

Barrier theme 6: Uncertain future

- Certification of bio-based plastics can be complicated, taking years to develop.
- It is unclear how the market will develop, and governments are not taking an active role.
- There is a strong lobby of oil companies.
- Bio-based plastics are a rapidly developing field, which is difficult for companies.

Barrier theme 7: Material properties

- The aesthetics of bio-based plastics may be perceived as less desirable or of lower quality.
- Bio-based plastics properties may not meet material regulations such as fire safety or skin contact.
- Material composition and properties could vary depending on the source.

## Discussion

Figure 2 presents an overview of the driver and barrier themes and illustrates the tensions between them. The observations are broadly in-line with pre-existing research. There is a tension between the positive public perception of bio-based plastics and their high costs. Bio-based plastics are more expensive than regular petrochemical-based plastics, which is often seen as a barrier (Álvarez-Chávez et al., 2012; Brockhaus et al., 2016; Rai et al., 2021).

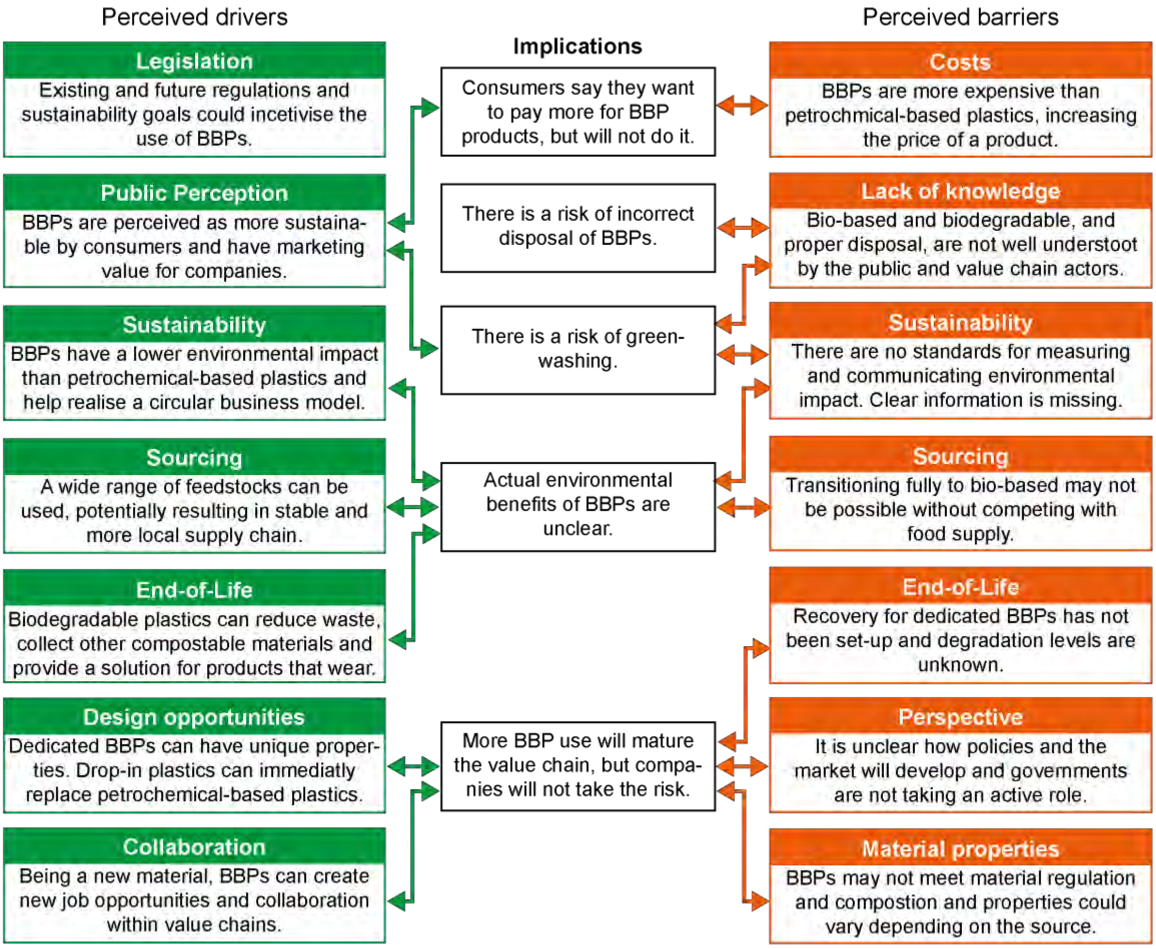

**Figure 2. Overview of drivers and barriers for using bio-based plastics (BBP). Tensions between the drivers and barriers are highlighted in the middle column.**

The public perception of bio-based plastics is positive, and consumers state that they would pay an increased price for a bio-based product (Kainz et al., 2013), but not everyone follows through on their stated willingness to pay more for a bio-based products (Barber et al., 2012; Prothero et al., 2011). This value-action gap is a common phenomenon for more sustainable products.

Despite their positive perception, the general public's knowledge about bio-based and biodegradable plastics is poorly developed (Dilkes-Hoffman et al., 2019). Using bio-based plastics could therefore be risky, according to the participants. The use must be communicated clearly to the consumer in order to justify an increased cost. When bio-based plastics are applied in durable products, the bio-based aspect is typically mainly reflected in marketing (Bos et al., 2022). However, the concept of bio-based plastics is complex, and the sustainability of the plastics is not entirely proven. This puts a company at risk of being accused of greenwashing.

The lack of public knowledge also extends to the recovery of bio-based plastics, combined with a lack of recovery infrastructure. Participants were concerned about proper disposal of bio-based or biodegradable products by end-users, and then by the reverse value chain. After use, drop-in bio-based plastics can easily integrate into existing recovery streams. However, these streams do not exist for novel, dedicated bio-based plastics, and there are no regulations or standards for their recovery at present (Briassoulis et al., 2019). Biodegradable plastics are not yet accepted in most industrial composting facilities (Álvarez-Chávez et al., 2012; Rai et al., 2021), and rarely fully disintegrate in home compost or nature (Lambert & Wagner, 2017). This creates the risk of doing more harm than good when using bio-based or biodegradable plastics.

Value chain actors themselves also lack knowledge about bio-based plastics. This already became apparent in the pre-workshop survey. Moreover, biodegradable plastics were often discussed during the workshop as if biodegradability is a property of bio-based plastics. However, biodegradable plastics are not necessarily bio-based, further highlighting the lack of knowledge and confusion. Furthermore, participants were not well informed about alternatives to the plastics used in their products. While bio-based packaging is already readily available, incorporating bio-based plastics in durable products requires the development of new knowledge.

Participants were divided on whether the environmental impact of bio-based plastics would be higher or lower than that of petrochemical-based plastics. Bio-based plastics are perceived to be more sustainable by many of the workshop participants as well as the general public (Brockhaus et al., 2016), but this is not yet confirmed by lifecycle assessment (Bishop et al., 2021; Walker & Rothman, 2020). Exploiting the sustainable image of bio-based plastics in marketing while the actual environmental impact remains uncertain can lead to greenwashing (Calero et al., 2021; Cardon et al., 2011; Nandakumar et al., 2021).

Most barriers and tensions appeared to originate in the immature value chain of bio-based plastics, which was considered a major barrier. During the workshop, this was labelled as an apparent causality problem, more commonly known as a chicken or egg problem. The immature value chain makes bio-based plastics expensive and poorly understood, resulting in unclear environmental benefits. The value chain cannot develop if bio-based plastics are not used more widely, but it is also a barrier to more widespread usage.

## Conclusions

Although knowledge about and experience with bio-based plastics was low for most participants, they expected that bio-based plastics would be used in their durable products in the near future. Workshop participants reported legislation and public demand for more sustainable products as the main drivers for using bio-based plastics in durable products in the telecommunications sector. Some existing legislation already incentivises the use of bio-based plastics, but participants expected future legislation to further promote bio-based. Bio-based plastics can be valuable in marketing and design, but the lack of knowledge and confusing terminology surrounding them require careful consideration in order to avoid greenwashing.

The circularity and sustainability of bio-based plastics were seen as a driver as well as a barrier. Bio-based plastics are perceived to be more sustainable, but the environmental benefits of bio-based plastics production and upscaling are still debated. Many bio-based plastics cannot be recovered at end-of-life as of yet. Notably, sustainability was not considered as important of a driver as legislation and public perception.

If bio-based plastics are to find widespread usage in durable consumer products rather than single-use packaging, their value chain needs to grow, and information is still missing. The bio-based plastics value chain will not mature by itself but requires government stimulation. Furthermore, bio-based plastic packaging options are readily available, but applying bio-based plastics in durable products requires the generation of new knowledge. There need to be more resources about what bio-based plastics are available and how they can be used in durable products. The sustainability of bio-based plastics needs to be further studied: the environmental impact and the effects of land-use change due to upscaling are not clear at present. Recovery at end-of-life also needs to be guaranteed.

b) Department of Chemistry, Materials and Chemical Engineering, Politecnico di Milano, Milan, Italy
c) National Interuniversity Consortium of Materials Science and Technology (INSTM), Florence, Italy

**Keywords**: Packaging; Sustainable materials; Circular economy; Zero waste; Life Cycle Design.

**Abstract**: Circular packaging materials are becoming increasingly relevant to ensure sustainable and environmentally friendly solutions for citizens and future generations. This work aims to present a glimpse of the current state of research by analysing fifty relevant case studies of packaging materials on the market or under development (for food, disposables, cosmetics, luxury, electronics, healthcare, etc.). The conducted analysis and clustering activity pointed out prominent development trends for incoming years. The study is supported by three multidisciplinary laboratory experiences of the Making Materials[1] research team of Politecnico di Milano, in which end-of-life packaging can be considered no longer a waste to dispose of but a new resource for subsequent production. The collaboration between all the stakeholders in the process is crucial to make this closed cycle work and be efficient.

## Introduction

The limited availability of fossil resources, increased pollution caused by traditional plastics and new regulatory restrictions have pushed companies to adopt more sustainable solutions, especially for short-term applications such as packaging. At both global (e.g., Agenda 2030) and European levels (e.g., the European Green Deal and the Circular Economy Action Plan), several strategies and action plans have been adopted to safeguard the planet and promote the use of alternative, environmentally friendly materials for both rigid and flexible packaging (European Commission, 2021; United Nations, 2021). Moreover, in 2019 the European Commission approved the Single Use Plastics (SUP) Directive, which requires the reduction of plastic in single-use applications by encouraging the development of benign and natural alternatives, not chemically modified (European Commission, 2019). Another important step towards the circular economy was taken in November 2022, when the European Commission published new rules for the Circular Economy Action Plan, which follows the ones presented in March 2022 (European Commission, 2022a). The primary focus of this second part is packaging and its related waste.

Unfortunately, the packaging industry is still strongly tied to the linear economy model, in which packaging is designed, produced, consumed and disposed of. Today, the main challenge consists in replacing the traditional linear economic system with a new production and consumption model that promotes the reuse and recycling of materials for as long as possible. In this way, the product's materials are recovered and fed back into the production cycle, reducing waste to a minimum and generating new value. This transition is not simple and immediate; it requires the synergetic effort and collaboration of all actors in the chain: suppliers, manufacturers, recycling processors, distributors, retailers, end consumers and waste service providers (European Parliament, 2015).

In the circular economy context, packaging design and materials choices are crucial in future sustainable innovation. It has been proved that 80% of environmental impacts derive from the design phase (European Commission, 2022b). The designer is, therefore, called upon to intervene in this circular transition phase by adopting a strategic eco-design approach: a sustainable design

[1] Making Materials is a multidisciplinary research group led by Professor Barbara Del Curto engaged in numerous university and corporate projects. The team's main research areas are material selection criteria, development of fibre-reinforced composites, additive manufacturing technologies, nanotechnology, materials and sustainability, smart/active packaging and CMF (colours, materials and finishes) analysis (Making Materials, 2020).

aimed at changing consumer behaviours and habits and ensuring a reduction in waste both at the production and consumption stages (Zeng et al., 2020).

## Packaging sector and materials selection

Packaging is now ubiquitous in our daily lives, allowing the containment and protection of goods, and facilitating efficient logistics operations. The global packaging market is expected to grow further in the coming years, reaching over $1.2 trillion in 2028 (Smithers, 2022), resulting in an urgent need for optimising end-of-life technologies. The new rules of the Action Plan for the Circular Economy, cited above, address the problems of the packaging sector and packaging waste in particular (European Commission, 2022d).

Plastics, due to their low cost, lightweight, good durability, mouldability and high barrier properties, are the preferred and most suitable materials for packaging (Filho et al., 2021). European data on plastic recycling recorded in 2020 indicates a positive trend since 2006, but unfortunately, even today, more than 23% of post-consumer waste is sent to landfill (Plastics Europe, 2021). In this case, the durability of plastic becomes a disadvantage: components dispersed in the environment take hundreds or thousands of years to degrade, accumulating in seas, oceans and beaches around the world. This leads marine species to ingest plastic residues that inevitably end up in the human food chain (Filho et al., 2021).

In this regard, the second part of the Circular Economy Action Plan focuses on two main aspects: a proposal for a regulation on packaging and packaging waste (PPWR) and a policy framework on biobased, biodegradable, and compostable plastics (European Commission, 2022c, 2022d). Therefore, European Commission intends to act on two levels: one that, in addition to preventing the production of packaging waste, aims to reinforce the reuse of packaging, increasing the quality of recycling and pushing for the use of secondary raw materials; the other focuses on regulating the implementation of biobased, biodegradable and compostable plastics. From the circular economy point of view, reuse and recharging are the lowest energy-consuming practices and enable the extension of materials and product life (Ellen MacArthur Foundation, 2019). Some cases of companies on the market are already present favouring high-quality materials to guarantee longer life and facilitate reuse, especially in the French and German context: one case is the reusable tableware to reduce waste in restaurants by Elium Studio[2].

Another critical point is recycling: recycled materials for packaging can be of various kinds, from paper to metal and polymer. While for paper or cardboard and the most widely used metals for packaging (e.g., aluminium) there are already well-established recycling chains and standards, for polymers there are some controversies (Ellen MacArthur Foundation, 2016). Firstly, it is necessary to clarify that collected plastic material for recycling is intercepted in two main stages: pre-consumer and post-consumer. In pre-consumer recycling, it is constituted of processing waste: the quality of the resulting product is very high since it has not yet faced external contamination and can thus easily return into the company's cycle. On the other hand, in post-consumer plastic recycling, many more variations and complexities come into play (Genovesi & Pellizzari, 2017); one problem is the variety of plastics on the market. In addition, the contamination with other substances and the regulations governing the use of recyclates often limit their applications. The chemical composition and, consequently, the additives differ considerably depending on the original product, which is mostly unknown (Eriksen et al., 2019). Legislations impose greater control and caution if the recyclate encounters foodstuffs in the application, thus limiting the uses in the food packaging sector, which is the largest source of plastic waste.

The PPWR pushes to increase the recyclate content in plastic packaging as early as 2030. It is foreseen that from 2030, each packaging unit containing plastic parts will have to include set minimum percentages of post-consumer recyclate (European Commission, 2022c):

- 30% in contact-sensitive packaging made with polyethylene terephthalate (PET) as the main component;

[2] Source: https://elium.studio/project/mcdonalds-re-use/

- 10% in contact-sensitive packaging made with plastics other than PET (excluding single-use plastic beverage bottles);
- 30% in single-use plastic beverage bottles;
- 35% in packaging other than those mentioned.

Undoubtedly, the recycled plastics sector still has much to improve to become efficient and help tone down the "war" against plastics, but it could have great potential in terms of the circular economy if rightly optimised.

Another topic mentioned in the Circular Economy Action Plan updates is bioplastics, an alternative to replace traditional fossil-based plastics in the packaging sector (European Commission, 2022c). According to European Bioplastics[3], a plastic material is defined as bioplastic if it is bio-based[4], biodegradable[5] or has both characteristics (European Bioplastics, 2019). The great advantage lies in using renewable resources, thus conserving limited fossil stocks and reducing carbon emissions. In addition, the compostability [6] of some bioplastics offers a new solution for their disposal at the end of the life cycle (European Bioplastics, 2019).

The bioplastics market is constantly growing, as shown by studies and continuous innovations in this field. The global production capacity of bioplastics is set to increase from around 2.23 million tonnes in 2022 to about 6.3 million tonnes in 2027 (European Bioplastics, 2022).

The European Commission's communication aims to shed light on these materials so that their use has a positive environmental impact (European Commission, 2022c, 2022d). The guidelines stipulate that the biomass used in biobased plastics must come from sustainable sources and respect the principle of "cascading use": i.e., prioritising waste and organic by-products as feedstock. Regarding communication aspects, generic definitions such as "bioplastic" and "bio-based" should be avoided by specifying the product's exact share of bio-based plastics. Also, the time and environment of degradation should be indicated, and artifacts with a high risk of dispersion in the environment should not be labelled as biodegradable. Moreover, the use of biodegradable bioplastics must be limited to specific applications for which the environmental benefits and value for the circular economy are proven in order not to incentivise waste dispersion (e.g., mulching cloths). Similarly, compostable plastics should only be used if they have environmental benefits, do not adversely affect compost quality, and where there is a system for collecting and treating organic waste. The products that must be made of such materials are listed in Art. 8 of the PPWR (tea bags, coffee capsules and pods, fruit and vegetable stickers and plastic bags made of ultralight material). Communication should always indicate that the products are certified for industrial composting in line with EU standards and indicate disposal methods using appropriate pictograms (European Commission, 2022c).

A further alternative to fossil-based plastics is biocomposites. They are defined as composite materials consisting of a matrix and a reinforcement of natural fibres (Fazeli et al., 2019). The tasks of the matrix are to hold the fibres together, transfer loads to them, and protect the fibres from environmental degradation and mechanical damage during the product's usage. The fibres used are often

[3] European Bioplastics is a European association founded in Germany in 1993. The organisation is responsible for raising awareness across all relevant stakeholder groups about the benefits of bioplastics. The mission is to reduce the dependency on fossil resources by promoting renewable ones (European Bioplastics, 2022).

[4] Bio-based refers to the fact that the polymer is either entirely or partially obtained from biomass, i.e., from any renewable organic material of biological origin and organic waste (European Bioplastics, 2022).

[5] Biodegradable is the material's ability to convert into substances such as water, carbon dioxide and compost through the chemical process initiated by microorganisms present in the environment (European Bioplastics, 2016).

[6] Compostable defines the ability of the material to decompose biologically under controlled conditions (e.g., a certain temperature, time, etc.). The result of the decomposition process is compost: a biologically stable, inert and odorless organic substance, consisting mainly of humus, active microorganisms and microelements, which can be reused in the agronomic field, for example as a fertilizer (European Bioplastics, 2016).

derived from totally bio-based and renewable sources, such as crop fibres (cotton, flax or hemp), recycled wood, wasted paper, by-products of crop processing, etc. (Sengupta et al., 2017). Regarding sustainability, composites represent a critical materials family since the presence and non-separability of different materials should be a disadvantage. Some biocomposite can be bio-based, biodegradable or compostable, following the rules of the PPWR mentioned above, or some biocomposite material could be presented as recyclable. In this case, the company should establish a circular network or returning system and ad-hoc recycling chain, not compromising existing ones.

The packaging materials application landscape is highly complex and diversified. Without analysing material and its applicative relationship in a real context, it is useless to make sustainability judgements; there are many false myths created around "circular" materials to date. For this reason, this study takes an analytical approach to circular packaging materials, as will be seen in the next section.

## Case study mapping

This paper provides an overview of sustainable and circular packaging materials from an in-depth literature search. Making Materials group not only experiments with new materials, as will be shown later, but keeps the trends of new materials under control through systemic mapping (Papile et al., 2022). The case studies presented below were analysed according to the aspects taken into consideration by the research team with the integration of Life Cycle Design (LCD) elements. The LCD methodology (Vezzoli, 2017) considers pre-production (type of resources and raw materials), production (material preparation and processes), distribution (proximity to a local supply chain), use (durability, performance and use/reuse patterns) and end-of-life (disposal and recovery system). All collected data were summarised in Rawgraph[7] flowcharts that offer a clear and intuitive reading of the emerging material solutions.

Fifty circular packaging materials have been mapped, referring to different packaging sectors, contexts, and levels. As shown in Figure 1, the cases belong mainly to food, general product market, cosmetics, disposables, healthcare, luxury and finally, electronics and agricultural packaging sectors. Most of these circular materials for packaging are already industrialised and apply to the consumer market, while only a few cases (n=7) belong to research still in progress or being industrialised.

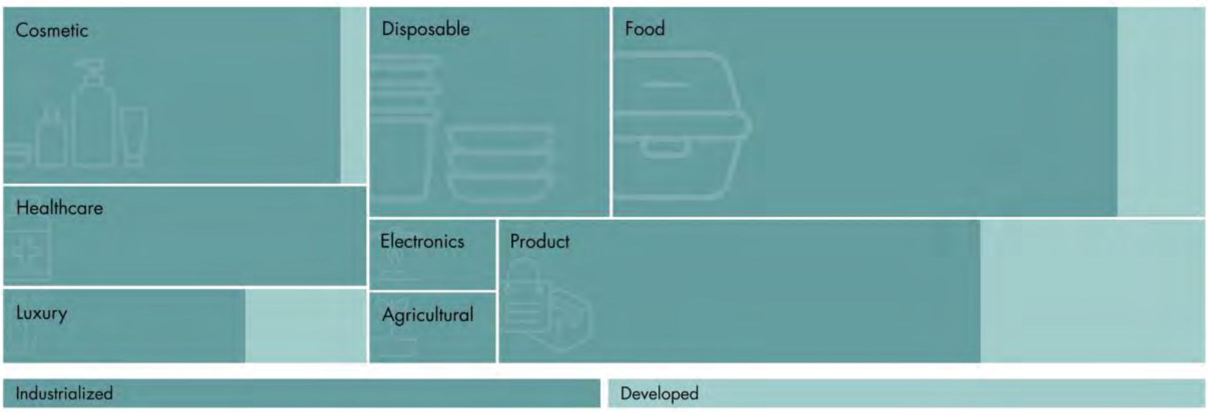

**Figure 1. Application fields and maturity level of the analysed case studies.**

[7] Source: https://www.rawgraphs.io/

To have a complete overview of the cases studied, they have been mapped by continent and geographical area. As can be noticed from figure 2, the materials mainly originate from Europe, America and finally, Asia; with some countries positioning themselves as major innovators. The year of development of these materials was not easy to identify (only for 31 out of 50 cases), but they mostly cover the time span from 2016 to 2021, as reported in the same picture.

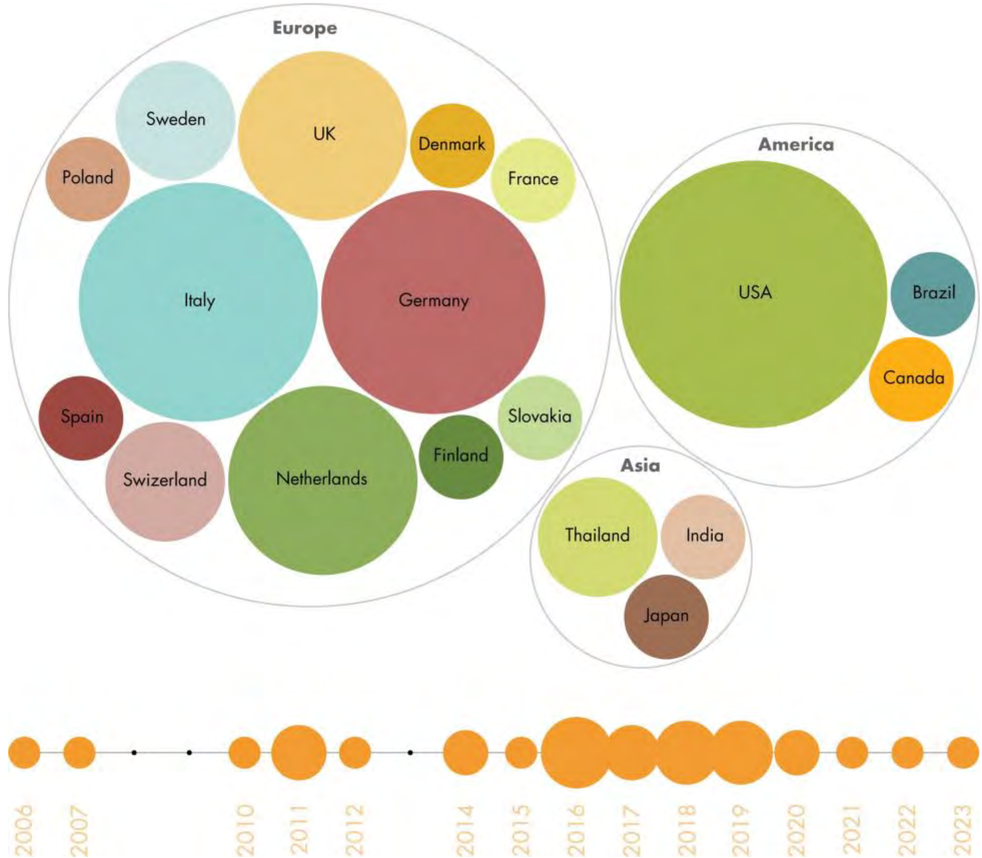

**Figure 2. Geographical and temporal distribution of the analysed case studies.**

From the extensive mapping of cases, some fields of investigation were extrapolated that were particularly relevant: composition and end-of-life guided the division of cases into emerging lines of research for circular packaging materials. In the visualisation shown in Figure 3, it is possible to find from left to right: the materials and their developers, their composition and clustering into the different research trends tracked. The clustering activity conducted pointed out prominent development trends for incoming years.

In order from the least to the most populated, these are:

- Edible: referring to the food packaging sector, these materials will be consumed together with the packaged food such as dissolvable noodle packaging by designer Holly Grounds[8];
- From recycle: materials entirely from post-industrial or post-consumer collections such as PP Repro by EFS Plastics[9] or from waters such as OWP+ by Pack Tech[10];
- Others: The most ambiguous cases were collected here, with compositions ranging from animal waste (e.g., plumage in the case of Pluumo by

[10] Source: https://www.oceanwasteplastic.com/

Aeropowder[11]) to recycled textiles as in the case of Nazena by Nazena Sr[12], to mycelio like Mushroom packaging by Ecovative Design LLC[13];

- Cellulose based: mainly composed of cellulose fibre or derivatives, with possible additional waste materials like leather in the case of Remake by Favini [14] or vegetable fibres from tomato plants such as Solidus solution[15];
- Biocomposites: composed of a bioplastic/recycled matrix plus a natural filler like Artichoke fibres in the case of Alveolo da carciofi by IIT [16] or fibres from meadow grass in Agriplast by Biowert[17];
- Bioplastics: Bio-based and/or biodegradable plastics like BIO-PE (Bio-polyethylene) as I'm green PE by Braskem [18] or Terralene HD 4527 by FkuR [19], and materials PHA (polyhydroxyalkanoate) based as for example YOPP PHA by Mango materials[20].

Notwithstanding the importance of the origin of materials, to ensure their circular life cycle, must be considered the stages of production (energy required for the transformation), transport (affected by geographical proximity), use and disposal (by the entire supply chain and the consumer), and finally the end-of-life, the last step, which can help to close the circle. Most of the materials mapped in this research and summarised in Figure 4 resulted as certified to be compostable, returning to nature by industrial or home composting, technologies in development in most of the studied countries. A large part of materials resulted as mechanically recyclable, although authors are aware that this only occurs in the presence of established supply chains or adequate return systems. While edible, biodegradable and incinerated materials do not assure systemic circularity.

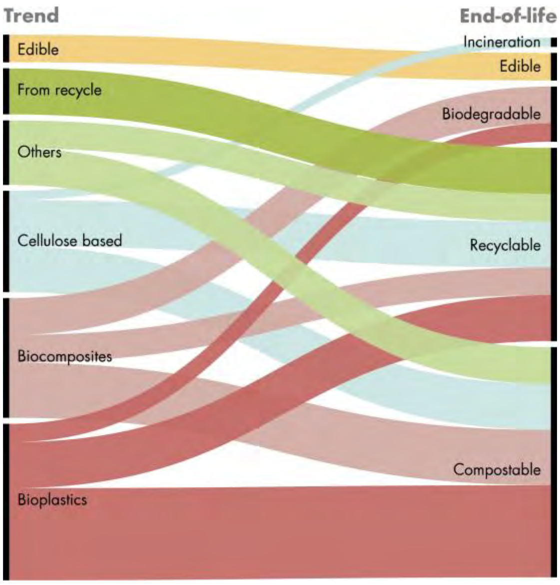

**Figure 4. RAWGraph flow chart highlighting the end-of-life of materials belonging to different emerging trends.**

## Laboratory experiences Making Materials

The Making Materials research group conducted three multidisciplinary laboratory experiments at the laboratories of the Department of Materials Chemistry and Chemical Engineering "Giulio Natta" at the Politecnico di Milano (Milano Bovisa), support the case study analysis carried out and the new emerging trends. Specifically, the experiments were carried out as master's thesis activities and involved the development of new biocomposites for the packaging sector by combining different bio-based, biodegradable and/or compostable matrices with bio-based fillers derived from organic waste, industrial by-products or recycled sources.

The first example is Poly-paper, traceable to the "cellulose-based" trend previously mentioned, a composite material obtained from a fossil-based and biodegradable bioplastic reinforced with up to 60% w/w of recycled cellulose fibres. The result is a material suitable for packaging applications that can be recycled in the paper and cardboard chain and processed like a conventional thermoplastic polymer. The project aimed to integrate the high production versatility of plastic with the high level of recyclability of paper (Santi et al., 2021).

**Figure 5. Case study #1: Poly-paper 3D printed packaging.**

Another project, positioning between the "cellulose-based" and "biocomposite" trends, involved the development of a composite from 100% bio-based and compostable materials, specifically a polylactic acid (PLA) matrix reinforced with microcrystalline cellulose (MCC). PLA and MCC were selected for their biological nature, wide industrial availability, their biodegradability (MCC) and compostability (PLA). Once the compound was extruded in the different composition ratios, several tests were carried out to fully understand its properties. The mechanical characterisation showed that the new material called PLA:ce has similar properties to ABS and PS, which was useful to identify possible fields of application, including the packaging sector (Marinelli, 2018).

Finally, POMOPLA² is a more recent master's thesis project carried out in collaboration with the Istituto Italiano di Tecnologia (IIT) in Genova. The material is based on polylactic acid (PLA) reinforced with tomato waste, resulting in a new high-performance biocomposite that reuses the by-products from the agri-food industry for both rigid and flexible packaging. The cooperative Finagricola (Battipaglia, Italy) was selected as a possible partner interested in the recovery of its by-products. In addition, a natural, biodegradable plasticiser was added to the matrix to improve the toughness of PLA and expand its market to flexible packaging. Following the principles of circular economy, the idea is to give a second life to tomato production waste through the development of POMOPLA², a promising substitute for the current packaging in PP, PE and PET used by Finagricola for fresh tomatoes (Rotondo, 2022).

**Figure 6. Case study #3: POMOPLA² 3D printed packaging prototype.**

In an ideal system (see Figure 7) if POMOPLA² passes the ongoing tests of biodegradability and compostability, the packaging after use can be composted together with the remaining tomato residues (branches, peels, etc.). In composting plants at elevated temperatures and humidity, the organic waste is processed to obtain compost, a natural and ecological fertiliser that can at least partially replace chemical fertilisers for a new agricultural production. Starting from nature, the extent is to return to it through a responsible and endless cycle (Rotondo, 2022).

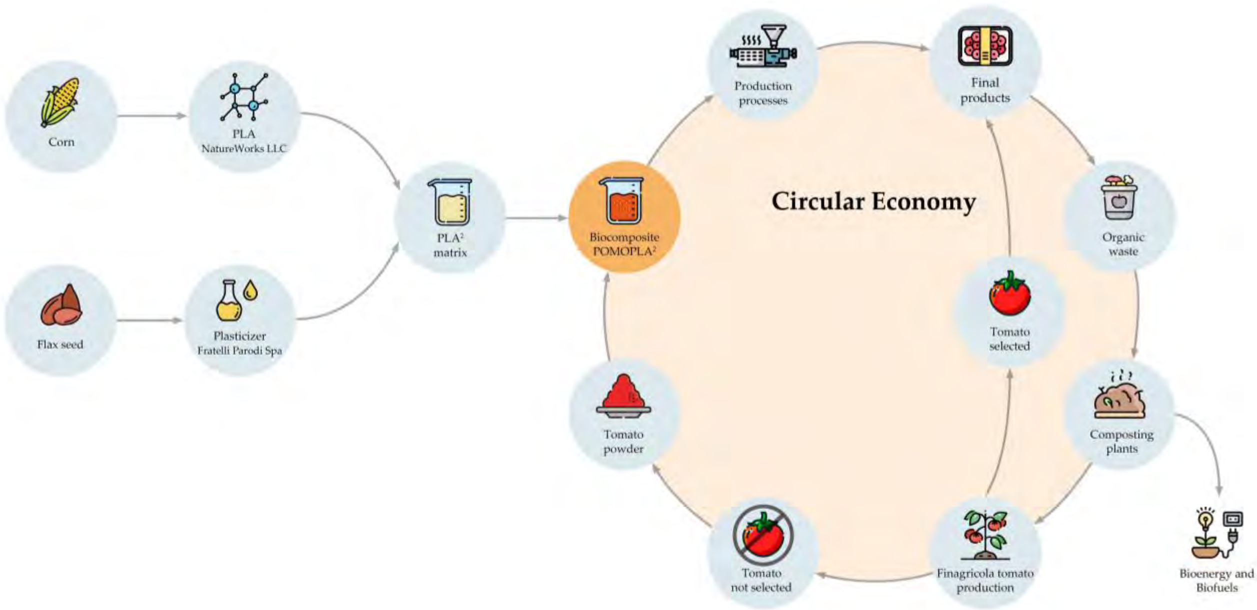

**Figure 7. Case study #3: POMOPLA² ideal life cycle.**

## Conclusions

Circular materials are gaining more and more interest, as demonstrated by the analysis and exploration of the case studies illustrated above. However, it is important to emphasise that not all the solutions presented have the same level of circularity and sustainability. Before selecting the right material, it is important to identify the requirements for the specific end application and to understand the entire life cycle of the product and, thus, of the related material. Adopting eco-design strategies during the packaging development phase makes it possible to achieve a good level of eco-efficiency of the product by considering all related environmental, economic and social aspects.

The research is an ongoing activity, continuously expanding the circular materials database to stay updated with new emerging solutions in the packaging sector and to provide a comprehensive and detailed overview that can be consulted and easily used by companies, start-ups and universities. The library will also show current trends and guidelines for developing new sustainable materials following the circular economy principles. Cycles in which a close synergy between all players in the system is necessary, not forgetting the consumer, who must be informed and educated on the correct use and disposal of materials through appropriate labelling and awareness campaigns. By adopting a collaborative and cooperative attitude, it would be possible to develop more environmentally friendly packaging solutions and help preserve the planet's resources, giving new life to scraps and generating zero waste.

# Too much information? Which labelled product property influences customers' purchasing decisions most

**Jana Rückschloss[a], Karsten Schischke[a], Moritz-Caspar Schlegel[b], Jonathan Zöllinger[a]**
a) Fraunhofer Institute for Reliability and Microintegration IZM, Berlin, Germany
b) Federal Institute for Materials Research and Testing (BAM), Berlin, Germany

**Keywords**: EU Energy Label; Consumer behavior; Smartphones; Energy efficiency; Repairability.

**Abstract**: The individual willingness to pay for sustainable products is significantly influenced by the climate crisis, but is also affected due to additional international crises as the still ongoing pandemic and the war in Ukraine. The better a product labelling is designed, the more likely consumers are to make a well-considered purchase decision at the point-of-sale, which in turn increases the product lifetime of the devices.

The results of this study are based on two consumer surveys with a total of 590 participants. Consumers were asked to make a simulated purchase decision based on the upcoming EU Energy Label for smartphones. Each consumer was presented comparison labels showing different aspects concerning durability (meaning charging cycles, robustness and IP class), repairability, energy efficiency and product price. In addition, there was a question on energy consumption, which was displayed either in Wh/h or in battery endurance per charge in hours.

The analysis of the survey shows a clear ranking of the preferred properties: 1. Durability as best option, Energy efficiency and Repairability as second and third choice. In all categories, a higher price was accepted in favor of a more environmentally friendly product design. When presenting the energy consumption in Wh/h, no reliable distinguishing between higher or lower values was observed. In contrast, higher values were clearly preferred when choosing between different battery runtimes.

Recommendations will be developed for adjustments to the upcoming EU Energy Label for smartphones and other product labels in the future showing circular economy aspects, such as the durability, repairability, recycled content used during production, recyclability or the total footprint of the product.

## Introduction

Today's global crises such as climate change, resource scarcity and increasing energy prices are leading to a rethink of the current economy. This includes prioritizing personal demands and sharpening consumption profiles, especially from the consumer's point of view. Therefore, consumer information on product properties, based on reliable data and presented in an appropriate manner, is key to at least inform, but better trigger, sustainable purchase decisions by consumers. The results of surveys and studies conducted in recent years confirmed the trend towards longer use-phases of products coupled with the acceptance to spend a higher price for the individual mobile devices (bitkom, 2022; Counterpoint Research, 2023; IDC, 2023). Summarized, consumers are buying fewer devices but in higher price categories. E.g., the estimated smartphone replacement cycle in Europe is 40 months on average – which is eight months longer than in 2016 (Duthoit, 2022). For 87 % of the consumers, a long update availability is an important purchase criterion (Haas, 2023).

In this study, the influence of different types of information and their display at the point of sale was analyzed using smartphones as an example. This product category was very prominent due to the legislative process on EU energy labelling of mobile phones and tablets under Energy Labelling Framework Regulation (EU) 2017/1369 and Ecodesign Framework Directive 2009/125/EC (European Commission, 2022). A consumer survey was conducted to determine consumers' interest in sustainable aspects such as durability, repairability, energy efficiency, etc. and their willingness to pay a higher product price for the improvement of these attributes. The results indicate clear priorities and finally let conclude that consumers are willing to choose a sustainable product option if background information at the point of sale is available.

## Method

Two consumer surveys with a total of 590 participants (already cleaned of incomplete entries or obvious misentries) have been carried out. The first survey was conducted at the IFA 2022, the largest consumer electronics trade fair in Europe. A total of 84 people participated in the survey, who are likely to be technologically oriented, because of their interest in attending a consumer electronics trade fair. In addition, the participants as interested in sustainability topics as well, because the survey tooks place at the "IFA Next", the part of the fair which was promoted as program with focus on sustainability. The second survey have been conducted online via the c't magazine newsletter (a specialized print and online magazine for electronics and ICT) three months after the IFA fair. 509 participants answered the questionnaire.

Consumers were asked to make a purchase decision based on the EU Energy Label (European Commission, 2023c) as Figure 1 and Figure **2** show. Smartphones were chosen as example because of both: (i) it is a widely used consumer product and (ii) the ongoing EU legislation concerning this product group coupled with the increasing awareness of new kinds of labelling within the common media. Each time, two simulated EU Energy Labels for smartphones were shown to the consumer, whereby two of the following aspects have been displayed divergent:

**(D)** durability (meaning battery charging cycles, robustness in repeated free fall tests and IP class for dust and water ingress protection),

**(R)** repairability,

**(E)** energy efficiency and

**(P)** product price.

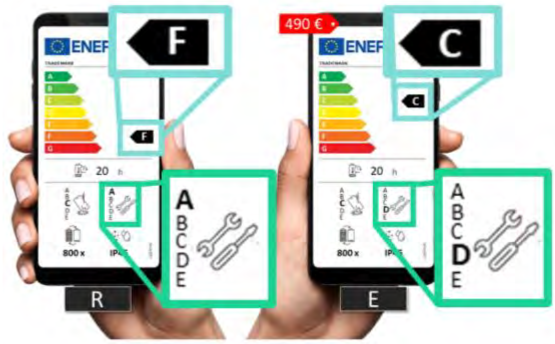

**Figure 1. "Which device would you buy?" – Survey screen asking for a purchase decision with divergent aspects (energy class and repairability).**

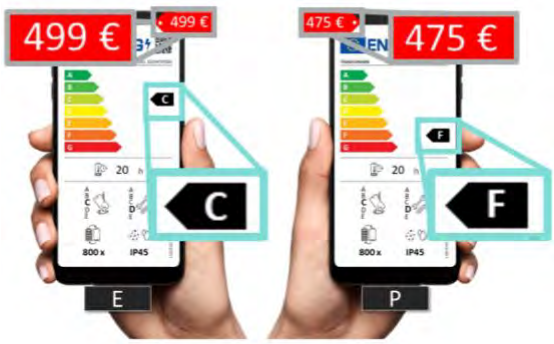

**Figure 2. "Which device would you buy?" – Survey screen asking for a purchase decision with divergent aspects (energy class and price).**

Individual respondents were not given all questions, but always three out of six possible combinations (see Table 1). Overall, the survey comprised three combinations with a higher price for a more sustainable product and three combinations between the other three categories (energy efficiency, durability, repairability). In addition, there was a question on energy consumption, which was displayed either in Wh/h or in battery endurance per charge in hours.

The rationale for the set parameter values is derived from the Energy Labelling framework Regulation (EU) 2017/1369, which requires upon introduction of the energy efficiency label to leave the best classes unpopulated to incentivize further innovation in the market. That is why in the survey products at best are assumed to be in energy efficiency class C. The price difference of 5% between products of

**Table 1. Listing of the parameters in the simulated purchase decisions.**

different environmental performance reflects the results of a technical analysis, indicating that better environmental performance justifies cost increases only in a range well below 5% of the product purchase price (Schischke et al., 2021). The average smartphone price is roughly in the region of 500,- Euros (Haas, 2023).

Because of the time difference of three months between the two surveys and the by that time ongoing regulatory process, we decided to slightly adapt the presented Energy Label in terms of minimum requirements for the charging cycles. To be in line with the latest revision accepted by the European Commission (European Commission, 2022), we added 200 cycles on top of every charging cycle from the IFA survey. This should not change the comparability of the two surveys since the proportion of both values stay the same, but rather represents an updated proposal for an Energy Label.

## Results and Discussion

In each of the following Figure 3 to Figure 8, two aspects are shown comparatively counting the answers in total. The upper part of the bar represents the IFA replies, the lower part contains the c't data. The analysis revealed a very clear picture; a price up in favor of a more environmentally friendly smartphone is accepted in every simulated purchase decision. Durability (D) leads the ranking, followed by repairability (R) and energy efficiency (E). In the smaller survey conducted at the IFA fair, energy efficiency came second in the ranking, ahead of repairability, but with an anyhow rather small sample size. In the survey conducted online, the choice turned. In both cases, the choice between energy efficiency and repairability was not as clear-cut as when comparing the other aspects. For example, the purchase decision in favor of a durable device is surprisingly definite, with only 6.5% of respondents choosing the less expensive device.

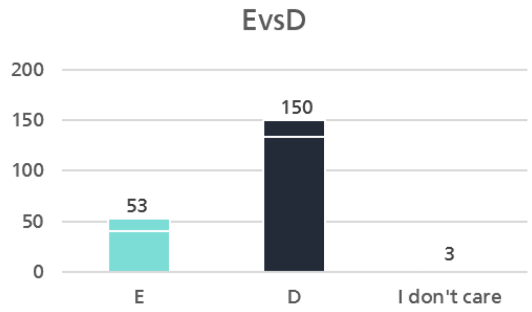

Figure 3. Energy vs. Durability.

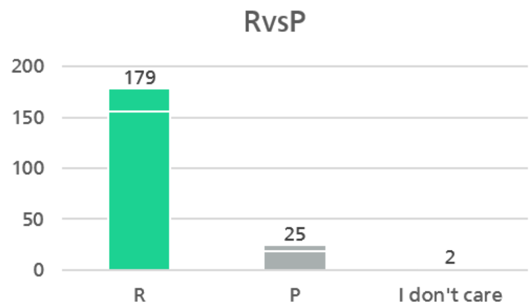

Figure 4. Repairability vs. Price.

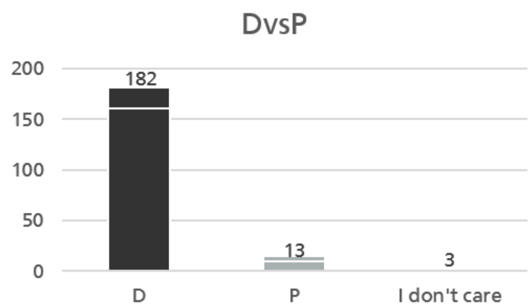

Figure 5. Durability vs. Price.

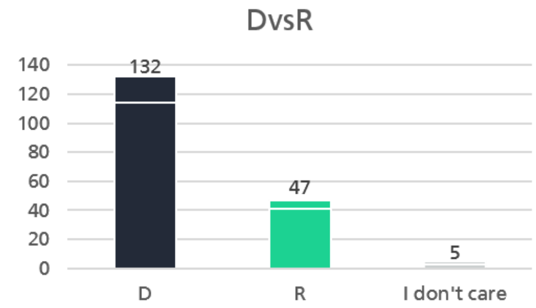

Figure 6. Durability vs. Repairability.

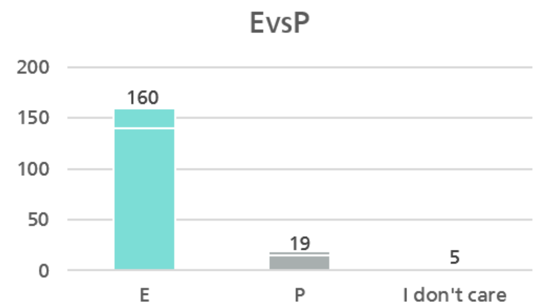

Figure 7. Energy vs. Price.

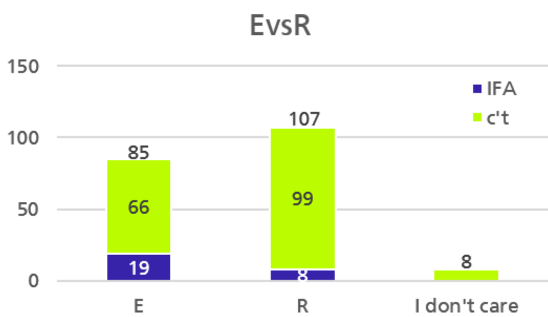

Figure 8. Energy vs. Repairability.

It is not possible to measure the degree to which the users would decide in a real purchase situation. The discrepancy between the answers given and actual behavior is difficult to assess here. For example, in a representative survey about use and repair of smartphones 31 % (317 from 1020 persons) had a defect in their smartphone, but 47 % of this group didn´t repair the phone afterwards (Erik Poppe, Melanie Jaeger-Erben, Anton Schaefer, & Clara Amend, 2022). Even if the planned environmentally friendly behavior is implemented less consistently, however, a positive incentive is likely. Society is increasingly prioritizing climate protection despite other important social issues such as flight and migration or the pandemic. This was the finding of a study conducted by the German Environment Agency in 2022 (Williams & Gellrich, 2022). Depending on the target group, priorities can change, as the results of our surveys also show. Online participants placed less importance on energy efficiency and ranked repairability higher. This is unsurprising among a target group from a magazine for electronics and ICT, who may tend to repair things themselves more often than the average person in society.

During the legislative process concerning the implementation of an EU Energy Label for Smartphones and Tablets in 2022, some stakeholders had argued, that an energy efficiency parameter, such as power consumption per hour of active use would be more consistent with the declaration of efficiency parameters on labels for other products. For this reason, a value in Wh/h should be favoured over a battery endurance in hours (DIGITALEUROPE). However, the survey clearly shows that the specification is not easily understood by end customers. Overall, 90 % chose the longer battery endurance, but only 65 % selected the lower Wh/h value. Even the tech-savvy target group in the second round of the survey selected the low Wh/h values less often in percentage terms than the comparison group selected a longer battery life (69 % and 89 %). This confirms the need for intuitively comprehensible information.

Further evidence is provided by the experience gained in another research project: as part of the scope3transparent 1 project, events were held with consumers to provide information about the environmental impact of smartphones. A total of over 900 people were reached in direct conversation. Recurring questions at all events were what would be the "best" device for the environment and if there are concrete, measurable figures for assessing the environmental impact.

## Conclusions

The consumer is aware of product labels, knows how to handle the given information and is able to include the displayed information in purchase decisions. The results of this study show that especially the durability of products is prioritized, even higher than the repairability of products. This matches also the prioritization of the European Commission, which prioritized durability as the most urgent topic for a potential horizontal measure (European Commission, 2023b). The urgency of labelling the product durability is also expressed by standardization activities, such as for washing machines (Commission Regulation (EU), 2021) or heating devices (European Commission, 2023a). The design of the EU Energy Label is centered around the energy efficiency scale with the green to red arrows, which is the right priority from an environmental perspective for many electrical and electronics devices which were subject to the EU Energy Labelling regulation in the past. For smartphones from an environmental perspective, the energy efficiency is much less important given the overall low power consumption compared to white goods or television sets. Therefore it is an important finding, that the consumer is not mislead by the dominating appearance of the energy efficiency scale and bases purchase decisions much more on those aspects, which in line with findings from smartphone LCAs (Sánchez, Proske, & Baur, 2022) contribute to lifetime extension through better durability and repairability. Also, the introduction of an A to E scale for drop resistances and repairability seems to be interpreted correctly by the survey participants although no further explanation of how theses scales are established have been provided.

Occasionally stakeholders raised some skepticism that the complexity of the proposed Energy Label depicting six different performance aspects might overwhelm the consumer. The rather clear tendencies in purchase decisions and the low number of “I don’t care” choices are an indication that the group of consumers who took part in the survey can deal with this complexity, at least when having the choice between only two devices.

During a literature review of normative documents according to the circularity of products (DIN / DKE / VDI, 2023) consumers awareness of product circularity was prioritized by the experts for electronics and ICT-products as one of the most important standardization activities accompanying the product legislation. The authors conclude that” making the information concerning the circularity of a product […] visible to the consumer, might push sustainable decision-making processes at the point of sale.“ (Schlegel & Giegerich, 2023). This was also confirmed by several discussions with consumers as mentioned before. The results of our surveys indicate that the proposed EU Energy Label, complemented by durability and repairability scoring, is an adequate means to communicate about important environmental and circularity aspects of smartphones. This insight however might

[1] Scope3transparent: Reduce greenhouse gas emissions in upstream supply chains and through changes in purchasing and consumption behavior in business and society. https://www.scope3transparent.de/

lead to the effect that OEMs and retail will put a price premium on those devices, which perform well on the energy label criteria, which then might exceed the 5% price increase assumed for the environmentally better performing devices.

## Acknowledgments

This presented study was conducted within the research project „Scientific Studies on Increasing Energy and Resource Efficiency of Products“, financed and commissioned by Federal Institute for Materials research and Testing (BAM) and German Federal Ministry for Economic Affairs and Climate Action (BMWK).

(d) College of Agriculture and Environmental Sciences. University of California Davis, United States

**Keywords:** Mycelium composites; post-consumer textile waste; materials design; myco-fabrication; *Pleurotus Ostreatus*.

**Abstract:** Mixed fiber textile waste is a significant problem of the textile and fashion industry because of the difficulty of separating natural/synthetic fiber blends prior to bioconversion processing. Repurposing mixed fibers can extend the life cycle of this waste stream, diverting it from landfilling and incineration, lowering carbon emissions. Biofabrication is an emerging technology for the revalorization of these types of waste into materials with a diverse range of applications. In our work, we use fungal mycelium, for its ability to break down and bind to complex compounds, such as those present in mixed textile fibers.

In this paper we present experimental procedures and results on manufacturing processes and compressive behavior of mycelium composites prepared from inoculation of oyster mycelium (*Pleurotus Ostreatus*) into textile waste mixed with local agricultural waste. We then discuss environmental implications in the lifecycle of the resulting materials and the waste streams involved. Our objective is to investigate the repurposing of mixed-fiber textile waste into light-weight composite structures for potential use in low load bearing engineering applications.

The results of this research intend to inform the emerging field of Sustainable Materials Design, Materials made from Waste, and DIY Materials, contributing solutions to economic, environmental and social problems created by waste, as well as to highlight the opportunities for development based on the understanding of this waste as a resource.

## Introduction

### *Mixed-fiber textile waste*

Mixed-fiber textile waste became a problem for solid waste management in the textile and fashion industry with the popularization of the use of synthetic polymers in yarns, fabrics and finishes. Nowadays, 70% of the world's textile consumption corresponds to synthetic fibers, such as nylon, acrylic, polyester, spandex and polypropylene, which are polymers derived from petroleum extraction (Echeverria et al., 2019). In the last two decades, favored by the so-called fast fashion phenomenon, the apparel sector (largest global consumer of textile fibers, Textile Exchange, 2016) has increased production rates, surpassing records of 100 billion items per year in 2015. This represents an ecological disaster in terms of pollution and solid waste management, considering that fast changing collections have decreased clothing utilization rates down to 70% compared to 15 years ago (Ellen MacArthur Foundation, 2017) and that traditional pattern-making systems waste between 10 and 20% of the input material in the cutting process (Rissanen, 2005). It is estimated that in 2015, 16 million tons of textile waste were produced in the United States, of which only approximately 15% could be recycled or reused; the rest was incinerated (19%) and sent to landfills (66%), which eventually impacts soil and waterways health.

Mixed fiber textile waste can be found along all the sector's value chain as post-industrial, pre-consumer and post-consumer textile waste, e.g cutting scraps, unsold inventories and used clothes, respectively (Kamble and Behera, 2021). The guidelines of the waste management hierarchy suggest reducing, reusing and recycling before resorting to energy recovery by incineration and disposal in sanitary landfills (European Commission, 2008). Reduction strategies range from conscious consumption to zero waste pattern systems. Reuse involves extending the life cycle of still functional garments and fabrics in local second hand markets, or through exports that touch the controversial topic of waste colonialism (Stebbins, 1993; Peirson-Smith and Craik, 2021; Manglou et al., 2022). In terms of recycling, product, material and raw-material recycling systems (Piribauer and Bartl, 2019) applied to textile waste face the challenge of finding ways to recover the energy potential of different mixed materials. Some studies have found chemical and biochemical methods to recover oligomers, polymers and monomers in mixed fiber residues; however, the scaling of these technologies to a commercial level is not yet feasible due to its high cost and complexity (Echeverria et al., 2019).

The repurposing of mixed textile fibers appears as one of the most viable options to divert this waste stream from landfilling and incineration, taking advantage of its energy potential. The design and engineering of materials has incorporated textile waste into numerous applications in the form of nonwovens and composites, with various applications in agriculture, construction, automotive, aerospace, textile and fashion, paper, and furniture (Shirvanimoghaddam et al., 2020). In the field of textile fiber-reinforced composites (TFRCs), there is a demand for biobased and biodegradable alternatives for synthetic matrices and reinforcements that can lower manufacturing environmental impacts and insert these materials into the circular economy (see reviews by Kumar and Hiremath, 2020; Kumar Singh et al., 2023; Rakvanshi et al., 2023).

### *Biofabrication of textile waste composites with fungal mycelium*

Pure fungal materials and mycelium-based composites (MBCs) are grown using mycelium, the root structure of fungi (Haneef et al., 2017), and are one of the most promising emerging biomaterials with uses in varied fields including construction, packaging, agriculture, interiors and industrial design (Aiduang et al., 2022). They have a low environmental impact compared to synthetic homologous materials, as they require low energy processes to be manufactured (Burzynski, 2016; Stelzer et al., 2021), are able to store carbon from the atmosphere, helping degrade and at the same time revalorize lignocellulosic agricultural, forestry and food wastes; have high biodegradability (Van Wylick et al., 2022; Grimm and Wosten, 2018), and their material qualities can be tuned by modifying parameters such as fungal strain used, type of substrate, growing conditions and processing methods in order to obtain different physical, mechanical, chemical and biological properties (Appels et al., 2019). However, limitations exist, such as lower mechanical properties and durability with respect to fossil-based materials (Sydor et al., 2022), impacting their marketability..

The careful selection of fibers as reinforcements and the treatment of their surface (functionalization) to promote chemical adhesion to the binder material are typical steps in the manufacturing of composite materials. In MBCs, biodegradable textiles and fibers are seen as reinforcement and as scaffold in many works (Elsacker et al., 2021; Tabellini, 2022; SOM Foundation 2021), Parker 2019, Collet 2017, Helberg et al., 2019; and Nguyen et al., 2022). Remediation of toxic compounds and polymer degradation capabilities of fungi have also been explored in combination with textile wastes (Edvard, 2016; Sangosanya, 2019).

To the best of our knowledge, though, there is no study similar to this paper involving mixed-fiber textile waste as a reinforcement in MBCs, despite the capacities of mycelium for the revalorization and remediation of waste streams. In this study, we use substrate hybridization (Jones et al., 2020; Elsacker et al., 2021) and incorporate local agricultural waste and multi-material waste fibers as fungal mycelium feedstock, towards the development of materials for the construction industry. After introducing materials and methods, and results from proof-of-concept experiments, we discuss the environmental implications of mixing biodegradable and non-degradable components, reflecting on the gains and losses in terms of life cycle assessment for the waste streams involved in these materials, and for the resulting composites in the context of their possible applications.

## Materials and Methods

### *Manufacturing of the specimens*

A blue jeans still containing the information tag was picked from a textile waste collection bin at the Yolo County Landfill (California, USA), with the following fiber composition: 78% cotton, 2% elastane, and 20% polyester. It was cut into squares of approximately 25 mm x 25 mm, and shredded in a Vitamix blender for less than a minute, obtaining fiber lengths between 8 and 37 mm (Figure 1).

**Figure 1. Textile transformation process: garment a) with fiber composition tag. b) cut into strips, c) cut into squares, d) shred into shoddy.**

Aged dry almond shells were mixed with oak pellets (Mushroom Media Online), pulverized cover crop waste from local gardens, and used coffee grounds. Almond shells are an abundant by-product of the California almond industry, which owns 80% of the global market share, and are typically landfilled or incinerated into biochar for soil amendment. This biomass was homogenized to an average particle size of 2 $mm^2$ and distributed into 3 groups, labeled A0, A25 and A50, each of them containing 0%, 25% and 50% of textile waste by volume (fiber volume ratio), respectively. The shredded textile fibers were added to A25 and A50 batches, and homogenized again in the blender for 30 seconds at low speed (Figure 2). Each substrate was put into an autoclavable growing bag with a filter patch. Water was added to reach a 60% of water content in the total mass.

**Figure 2. substrate preparation: a) almond waste, b) substrate after homogenization in blender, labeled as A0; c) substrate with 25% fiber volume labeled as A25, d) substrate with 50% fiber volume, labeled as A50.**

Each bag was sealed with sterilization tape and sterilized in an Instant Pot pressure cooker at a working temperature of 115-118 deg. C and a working pressure of 0.70-0.80 bars (10.2-11.6 psi) for 1 hour. The use of Instant Pot as a low-cost and legitimate autoclave replacement is shown by Swenson et al. (2018). After cooling to room temperature, the content was poured into a bowl sanitized with 70% isopropyl alcohol, and inoculated using 10% by wet weight of in-house grain spawn mycelium that was prepared from a liquid culture of *Pleurotus Ostreatus* purchased from Root Mushroom Farm. The substrate was mixed by hand to ensure an even distribution of the grains. The procedure was repeated with each of the bags, to obtain a total of 3 different substrates (Figure 2).

Each bag's inoculated content was distributed evenly into a previously sanitized silicone ice tray mold (Mossime Store, Amazon.com) with 6 cubic compartments of 50 x 50 x 50 mm$^3$ each. The mold was selected according to the geometry requirements of ASTM C165-07 Standard for testing compressive properties of thermal insulations, and ease of extraction of samples from mold. The substrate was weighed every time to ensure that the same mass was put into each cube. Each filled silicone tray was put back into the growing bag, sealed and put into a controlled incubation chamber (Binder BD56) to guarantee a constant 25 deg. C during growth (Figure 3).

**Figure 3. Mycelium composite manufacturing process: a) filtered bags before their sterilization; b) inoculation with grain spawn and weighing before filling silicone trays; c) filled silicone tray; d) incubation of trays in the Binder incubation chamber.**

After 6 days, the specimens were taken out of the mold, flipped 180 degrees and left to grow for another 10 days inside the bags and the controlled incubation chamber. After a total of 16 days, the specimens were taken out of the incubation chamber and bags, and dehydrated in an Excalibur dehydrator at 35 deg. C for 24 hrs (Figure 4). The direction of growth in the silicone molds was tracked during the incubation process. The samples weights and dimensions were measured prior to testing of their compression properties.

**Figure 4. Growing and drying of 50 mm cube samples: a) growth after 6 days; b) flipped samples; c) samples after 16 days of growth; d) samples ready to dehydrate.**

### *Testing of the specimens*

A total of 17 specimens (5 for baseline (A0), 5 for condition 1 (A25) and 6 for condition 2 (A50)) were tested for compressive strength and modulus in an Instron 5965 screw-driven machine with a 1 kN load cell, following the aforementioned ASTM standard C165-07. The testing occurred at a displacement rate of 2 mm/min, with time, displacement and load data acquired every 0.5 s. The first end point was selected to be 15% deformation (machine displacement/(initial height), to compare our results with the published compression properties of commercial GIY mycelium hemp-based biomass by Ecovative Design (grow.bio). Then, an exploratory run of tests was conducted, re-testing some of the samples at double the strain, i.e. 30% deformation: one A0, one A25, and one A50 samples. After observing the considerable improvement of performance of the A50 sample at 30% deformation, discussed below, two more A50 samples were re-tested in those conditions (Figure 5).

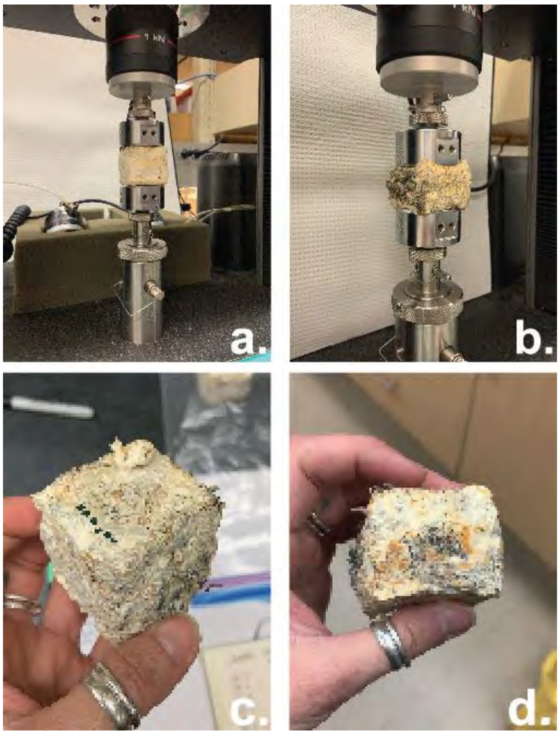

**Figure 5. Testing compressive behavior: a) test set-up; b) specimen A50-6 under 30% deformation; c) specimen A50-6 before compression; d) specimen A50-6 after 30% deformation.**

## Results

The compressive resistance is defined in ASTM C165 as the compressive load divided by the original cross-sectional area at a specified deformation; if the start of failure is observed, the compressive resistance may be called compressive strength. The data for 15% deformation (displacement/(initial height) is shown as average ± standard deviation. The data for 30% deformation is provided for one A0, one A25 and three A50 samples, and is meant as an exploratory step. The compressive modulus of elasticity is computed as the compressive load per unit of original area divided by the corresponding deformation per unit of original thickness, while the material is still linear. The load at a 2 mm machine displacement met the linearity criterion, therefore the compressive moduli of elasticity are measured then. Table 1 presents the test results for the following compressive properties: compressive resistance and strength at 15% (first test) and 30% (second test) deformations; compressive modulus of elasticity in the first and second tests.

| | A0 | A25 | A50 |
|---|---|---|---|
| Compressive resistance, strength at 15% (kPa), first test | 158.3 ± 34.75 | 132.3 ± 26.21 | 124.8 ± 15.97 |
| Compressive modulus of elasticity (kPa), first test | 1280 ± 207.9 | 1031 ± 237.3 | 971.1 ± 209.6 |
| Compressive resistance, strength at 30% (kPa), second test | 226 (+7.41%) sample failed | 242.4 (+97.7%) | 296.4 (+133%), 355.8 (+131%), 300.0 (+152%) |
| Compressive modulus of elasticity (kPa), second test | 1050 (-24.1%) | 598.6 (-32.9%) | 410.6 (-56.9%), 696.3 (-39.8%), 493.5 (-20.3%) |

**Table 1. Compressive test results for baseline (A0), (A25) and (A50) samples. The data for the first test is available as average ± standard deviation. Fewer samples were tested a second time; data in parentheses in red/green show the change with respect to the same sample's first test.**

Within the scatter of these tests (similar for the A0 and A25 sets, lower for A50 samples), the baseline samples seem to outperform the fiber-reinforced samples in the first test. This may indicate the need to improve the chemical affinity between the textiles and the fungal species. However, in the second round of test, the fiber-reinforced samples exhibit a considerable increase of compressive resistance, accompanied by a decrease of compressive modulus of elasticity. We hypothesize that the reinforced samples are becoming densified foam-like materials under repeated loading, and consequently their stiffness is decreasing. A50 samples in particular more than doubled their compressive resistance (Figure 6). The single baseline sample failed in the second test, while the reinforced samples upward trajectory hinted at further loading capability. This trend will be investigated in the future with further testing on the same samples.

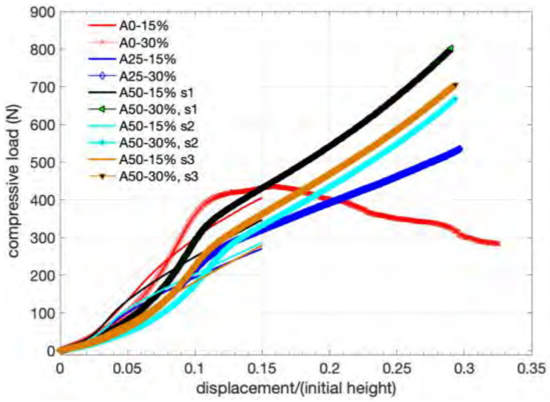

**Figure 6. Comparison of results for first (15% deformation/(initial height)) and second tests (~30% displacement/(initial height)) on the same samples.**

## Discussion

The most critical aspect of hybridizing a mycelium composite with non-degradable mixed-fiber textile waste is affecting the circularity of the resulting composite. Studies have found the biodegradability of mycelium composites to be very high, exhibiting signs of degradation after 6 weeks of exposure to outdoor conditions, and weight losses of up to 43% in soil burial tests (Gan et al., 2022). Adding textile fibers could decrease that capacity, but there could be gains in terms of service life. If MBCs are maintained under stable and favorable conditions, their lifespan can be of approximately 20 years (de Bruin, 2019). Sequestering textile waste in materials with a medium term lifespan has important environmental benefits. Published studies (Muthu et al., 2012a; Gadkar and Burji, 2015; Echeverria et al., 2019) have emphasized the extension of the service life of textile materials as the best way for mitigating the total carbon emissions generated by fibers as they decompose in landfills. Moreover, the longer service life counteracts the adverse effects for both humans and the environment, which are caused by organic compounds being released by incineration chimneys in thermal or electrical energy recovery. Gan et at. (2022) produced MBCs reusing spent substrate from a previous MBC biocycle, adding fresh biomass at a 50:50 ratio, obtaining material properties similar to the first biocycle of the material. This suggests that the materials proposed could be reused in a closed loop system with no significant downcycling.

## Conclusions

This study demonstrated the contribution of mixed-fiber textile waste to the compressive behavior of mycelium composites, a class of materials that could become in the longer term a viable replacement for fully fossil-based engineered materials, especially those with higher environmental impact currently being used in the construction industry.
Future work will be carried out to further characterize the properties of the materials resulting from the addition of mixed-material fibers, like water absorption, impact resistance, tensile and flexural properties, flammability and thermal conductivity. Also, we could envision scaling-up these techniques as a way of sequestering difficult-to-recycle waste streams in biodegradable matrices, while technologies for recovering fibers become more economically acceptable.
Soil burial degradation tests and chemical tests could also assess the effects of the fibers eventually entering soil and water streams, as well as suggesting if these hybrid substrates could be used to combine mushroom farming with biomaterials industry (Grimm and Wosten, 2018); this is a question to be explored from the perspective of design, materials science and mushroom farming.
Further research should be done on composting and recovering systems for these mycelium-textile composites, to demonstrate that the loss in biodegradability for MBCs is the gain in low environmental impact and circularity of textile waste fiber-reinforced materials. Furthermore, the capacity of fungi for degrading complex compounds could be explored through the development of cascading systems for composting them while also producing food and biomaterials.

## Acknowledgments

This research was carried out with funding provided by UC Davis The Green Initiative Fund (to A.R., grant F22-106) and Sandia National Laboratories (to V.L.S., 2022-2023 LDRD grant). The authors thank the support of Professors Christina Cogdell (Design), Laura Bogar and David Rizzo (Plant Biology), the Davis Mycology Society, the assistance of research engineer Shuhao Wan (Mechanical and Aerospace Engineering) during testing, and Tanya Garcia-Nolen (research engineer and manager of the testing laboratory UC Davis School of Veterinary Medicine).

# Mindfulness in apparel consumption: A perspective of Gen Z

**Dr. Harleen Sahni[(a)], Nupur Chopra[(b)]**
a) National Institute of Fashion Technology, Jodhpur, India
b) National Institute of Fashion Technology, Gandhinagar, India

**Keywords**: Mindfulness; Apparel consumption; Gen Z; Care; Temperance.

**Abstract**: The modern day consumers are viewing earth both as a "source", a supplier of various provisions, and a "sink", the destination of waste left over from the consumption of its resources (Sheth et al. 2011). Fashion is not indifferent to the demand for newness. Fashion consumption is driven by strong marketing strategies that are devised to groom the consumer to believe that by purchasing a specific product or service from a given brand, they will be able to fulfill their needs to be loved, respected and admired (Barandela, 2017).

In the wake of this the current research attempted to study 'Mindfulness' as a construct of young consumers' psychological and behavioural orientations. As Gen Z constitute the largest current and potential consumer segment for this product category, it is crucial to know their perspective towards mindfulness in fashion consumption. The research aimed at examining mindfulness in Gen Z towards apparel consumption on two attributes -"Care" and "Temperance" that depict mindfulness (Sheth et al., 2011). A structured questionnaire was designed on these two attributes and responses were gathered on a 5-point Likert scale from 300 fashion students. The responses were subjected to Factor analysis to draw the constructs that define mindfulness in apparel consumption for the selected category of consumers.

The findings revealed that mindfulness has unique comprehensions for Gen Z due to their specific psychographic and social peculiarities. It was found that while Gen Z fashion students depict a psychological orientation towards "Care" and "Temperance" in apparel consumption, there exist a significant dis-association between the two attributes when it comes to their behavioral orientations.

## Introduction

The earth's resources are limited, and the current rate of consumption and replacement is not likely to guarantee resources for sustenance of living things in a permanent manner (Ericson et al., 2014). Consumption is increasing at a rampant pace and while engaging in this 'pleasurable' activity that provides a sense of 'happiness', consumers tend to overconsume and over-dispose. Consumers are viewing earth both as a "source" and a "sink" (Sheth et. al. 2011). Consumers' need to purchase goods is so intrinsic to society that businesses have incorporated planned obsolescence when conceiving a new product (Talaat, 2020). Fashion is not indifferent to the demand for newness. Fast Fashion is a result of consumers' impatient and drifting fashion choices. Fashion consumption is strongly driven by marketing strategies, devised to groom the consumer to believe that by purchasing a specific product or service from a given brand, they will be able to fulfill their needs to be loved, respected and admired (Barandela, 2017).

## The Gen Z consumers

Generation Z (Gen Z) is the generation after Millennials, and the generation before Generation Alpha. With high aspirations, these 'new type of shoppers' possess unique consumption preferences and practices. The marketing efforts for this segment need to be specifically crafted (Puiu, 2016). They have strong purchasing power, well-pronounced demand for superior quality, branded and personalized products. 73 percent of Gen Z consumers are willing to pay 10 percent more for sustainable products. They are conscious of environmental impacts of human existence, thus facilitating the opportunity for sustainable business growth (Holman, 2020). Gen Z makes up around 32 percent of the global population and have a spending power of $143 bn (Raynor, 2021). It is vital for brands to create products that sufficiently motivate this segment, looking towards personalization at one end and social responsibility at the other. Gen Z is emerging as the sustainability generation (Petro, 2021). Prominent trends characterizing Gen Z consumers are (i) focus on innovation, ii) high insistence on convenience, iii) strong desire for security, and iv) pronounced tendency toward escapism (Wood, 2013). This segment is avid consumers of apparel products. Apparels is a product category where consumer involvement, especially that of young consumers, is significantly high. Apparel consumption is very individualistic, yet socially-driven. It is becoming a more complex phenomenon, driven parallelly by self-concept, social influence and a product- and situation-based mindfulness-mindlessness dilemma.

## Mindfulness in consumption

The world is over-consuming; and exploring mindful consumption has become paramount. The mindful consumption model proposed by Sheth, Srinivas, & Sethia (2011) explains consumers' 'Mindfulness' as a construct of Mindful mindset and Mindful behaviour. Mindful mindset is an individual's predisposition and comprehension of a caring mentality and inclination towards nature, self and community. Mindful behaviour explains consumption behaviour in terms of repetitive, acquisitive and aspirational. Figure 1 demonstrates a modified model of mindful consumption compiled by authors, based on elaboration of constructs of mindfulness.

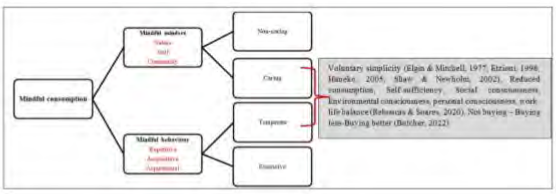

**Figure 1. Constructs of Mindful consumption [Modified and compiled by authors from Sheth et al. (2011) and Butcher (2022)].**

The two dimensions depict considerations during pre-consumption phase, and also the practices during buying/consumption phase. 'Care' is reflection of a mindful mindset which can be on a continuum of 'caring' to 'non-caring' for the major elements of human existence comprising of nature (environment, biosphere), self (individual well-being, happiness, satisfaction) and community (the social system). 'Temperance' is a depiction of mindful behaviour, and can be mapped on a scale of temperate to excessive. Consumption behaviour can be categorized as

- repetitive [buying same styles, or from same stores or brands repeatedly; re-experiencing an enjoyable stimulus in order to enjoy it again (O'Brien, 2021), following a cycle of buying-discarding-buying (Cohen and Darian 2000; McCollough 2007)]
- acquisitive [acquiring things at a scale that exceeds one's needs, or even one's capacity to consume, (Schor, 1992, Arnold and Lang, 2007] and
- aspirational [most easily recognized form of excessive consumption is associated with the idea of conspicuous consumption (Schor, 1999)]

Mindfulness is the art and practice of focusing on improved awareness and attention. It calls for reflection on one's attitudes and behaviour. Sheth et. al. (2011) expound Mindful Consumption through sustainability metrics for evaluating consequences of business behaviour holistically in terms of personal, environmental, and economic well-being. Mindful consumption includes consciousness about impact of consumption on environment starting from product procurement, storage, and disposal (Sheth, 2017).

Consumption satisfies the basic necessity for human survival. Consumption has also been identified as a measure of welfare and economic growth. But in the past few years, an uncontrolled consumption phenomenon is being witnessed among mainstream middle and higher income groups. This has both negative and positive consequences for consumers, society, environment and businesses (Westra and Werhane 1998; Quelch and Jocz 2007). Mindful consumption, is an inescapable necessity, and has a strong environmental perspective; it fits well with the new frugality embraced by consumers (Sheth et al., 2011).

Mindfulness can be explained through the Attitude-Behaviour model (Frazier and Sheth, 1985). Individuals' attitudes toward a

behaviour will predict whether or not they will perform that behaviour. The model indicates considerable inconsistencies in attitudes and behaviours of consumers. Sheth et al. (2011) discuss about 'advancing mindful consumption' indicating the existence of a market for mindful consumption. They applied the Frazier and Sheth (1985) model to demonstrate four different consumer proclivities for mindful consumption based on the consumption behavioral propensity—excessive vs. temperate, and consumption attitude or mindset—caring vs. non-caring. thus reflecting mindful mindset through Care or Non-care and mindful behaviour through Excessive or Temperate dimensions.

1. *Caring Mindset*—Temperate Consumption: Consumers have a caring mindset and practice temperance in consumption.
2. *Caring Mindset*—Excessive Consumption: Consumers have a caring mindset, but are unwilling or unable to temper consumption.
3. *Non-caring Mindset*—Temperate Consumption: Consumers avoid excess consumption, but do not have a caring mindset.
4. *Non-caring Mindset*—Excessive Consumption: Consumers neither pay attention to their consumption levels, nor do they care about the consumption consequences.

## Methodology

The study specifically focused on fashion students, who have or acquire the awareness of, and sensitivity towards sustainability issues in a structured manner; and thus have a potential to adeptly comprehend the matter. The research subjects were Gen Z apparel consumers who were pursuing fashion education. There is a dearth of research that studies mindfulness in fashion consumption. As Gen Z constitutes the largest current and potential consumer segment for this product category, it is crucial to know their perspective towards mindfulness in fashion consumption. The research aimed at examining mindfulness in Gen Z towards apparel consumption on two attributes, "Care" and "Temperance" (Sheth et al., 2011). A structured questionnaire was designed consisting of a comprehensive set of 49 statements compiled from mindful consumption literature. Content validity of the statements was done with the help of experts from the area of apparel marketing, consumer behaviour, sustainability and circular economy. Statements were checked for clarity and relevance. The initial 49 statements were reduced to 41 after removing statements that seemed ambiguous, repetitive and irrelevant (Refer Annexure 1). There were 21 "Care" and 20 "Temperance" statements. Care statements were aimed at unveiling young fashion students' psychological orientations, attitude, and comprehension. These statements were primarily designed to gauge the 'Caring' and 'Non-caring' mindset of young consumers. "Temperance statements" were related to the behavioural orientations pertaining to considerations of product, brand, prices, use, social and environmental relevance, disposal etc. during purchase of apparel products. Responses were gathered on a 5-point Likert scale from 300 fashion students, and were subjected to Exploratory Factor analysis to draw the constructs that define mindfulness in apparel consumption.

## Analysis and Findings

Data was subjected to statistical analysis in SPSS 21. This section is organized into 3 segments -

**(a) Conducting demographic analysis –** Respondents' demography was comprehended through gender, qualification, age-groups, work profile and average monthly spending on apparels.
Frequencies depicting demographic profiling of respondents are depicted in Table 1.

| Gender | | |
|---|---|---|
| | Frequency | Percent |
| Female | 176 | 58.7 |
| Male | 124 | 41.3 |
| Total | 300 | 100.0 |
| **Qualification** | | |
| | Frequency | Percent |
| Graduate | 92 | 30.7 |
| Post-Graduate | 129 | 43.0 |
| Up to School Level | 79 | 26.3 |
| Total | 300 | 100.0 |
| **Age-group** | | |
| | Frequency | Percent |
| 18 – 22 years | 157 | 52.3 |
| 23-26 years | 126 | 42.0 |
| < 18 years | 4 | 1.3 |
| > 26 years | 13 | 4.3 |
| Total | 300 | 100.0 |
| **Profile** | | |
| | Frequency | Percent |
| | 1 | .3 |
| Entrepreneur | 2 | .7 |
| School Student | 2 | .7 |
| Student-Graduation | 144 | 48.0 |
| Student-Post Graduation | 135 | 45.0 |
| Working Profession | 16 | 5.3 |
| Total | 300 | 100.0 |
| **Average monthly spend on apparel** | | |
| | Frequency | Percent |
| Less than Rs 500 | 74 | 24.7 |
| More than Rs. 2000 | 72 | 24.0 |
| Rs 500 - Rs 2000 | 154 | 51.3 |
| Total | 300 | 100.0 |

**Table 1. Demographic profile of respondents.**

**(b) Identification of mindful apparel consumption factors significant to Gen Z** - Exploratory Factor Analysis (EFA) was used. EFA establishes relationship between large data sets through identifying correlations. Principal Component Analysis (PCA) was used with Varimax rotation.

EFA was conducted in two phases. In the first phase the 21 statements related to 'Care' dimension were subjected to analysis. The result of Bartlett's test of Sphericity (0.00) and KMO (0.752 > 0.5) indicated that data was appropriate for factor analysis. The twenty one items were extracted by seven factors. Only the factors having Eigen value greater than one were considered significant. All the seven factors together accounted for 68.514 percent of total variance. Rotated Component Matrix was examined for cross-loadings and insufficiency of items. No cross-loadings were found, however only two items loaded in factors 4, 5 and 7, and one loaded in factor 6. These four factors were eliminated from further analysis. The three factors retained were (i) Sustainability orientation (explaining 13.241 percent variance individually), (ii) Consciousness and concern (explaining 12.198 percent variance individually and (iii) Personal well-being and social space (which explained 11.982 percent of variance individually) (Refer Table 2).

| | Factors | Code | Factor loading | Specific attributes used in consumer survey |
|---|---|---|---|---|
| 1 | **Sustainability orientation** | A12 | .615 | Importance of concept of minimalistic clothing |
| | | A14 | .723 | Importance of concept of longevity in clothing |
| | | A15 | .764 | Importance of concept of reuse-repeat in clothing |
| | | A16 | .670 | Importance of concept of repurposing used apparel through donation/ collection centers |
| 2 | **Consciousness and concern** | A8 | .624 | Concern about huge amount of water usage in apparel production |
| | | A9 | .793 | Concern about increasing landfills due to fast disposal of apparel products |
| | | A10 | .780 | Concern about the use of animal-based contents in apparels |
| | | A11 | .767 | Concern about the working conditions of apparel production workers |
| 3 | **Personal well-being and social space** | A17 | .562 | Association of the concept of well-being with apparel |
| | | A18 | .665 | Association between apparels and social connections |
| | | A19 | .823 | Association between apparels and social image |
| | | A20 | .743 | Association between apparel consumption and consumers' personality |

**Table 2. Significant factors, factor loadings and Care statements.**

The Care factors that emerged significant for the Gen Z subjects in apparel consumption are depicted in Figure 2.

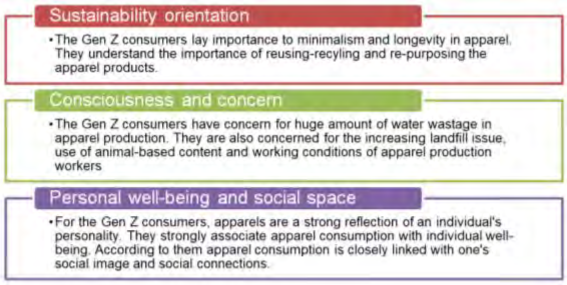

**Figure 2. Care factors significant for the respondents.**

In the next phase the 20 statements related to 'Temperance' dimension were subjected to EFA. Bartlett's test of Sphericity, with significance value of 0.00 and KMO value of 0.744 (> 0.5), confirmed data adequacy. Five factors, depicting 59.269 percent total variance were extracted in the Rotated Component Matrix. Items B6 and B10 were found to have cross-loadings in two factors, thus were eliminated. Factors 4 and 5 were found to have insufficient number of items, hence were dropped. A total of three factors emerged, (i) Responsible purchases (explaining 18.024 percent variance individually), (ii) Mindlessness in apparel consumption (explaining 12.044 percent variance individually and (iii) Pre-owned and shared apparel (which explained 10.993 percent of variance individually) (Refer Table 3).

| | Factors | Code | Factor loading | Specific attributes used in consumer survey |
|---|---|---|---|---|
| 1 | Responsible purchase | B1 | .720 | Considering the environmental impact of a product when making apparel purchasing decision |
| | | B2 | .720 | Considering the social impact of a product when making apparel purchasing decision |
| | | B3 | .657 | Paying more for an apparel product that is environmentally friendly |
| | | B4 | .667 | Making changes in apparel purchasing habits to be more environmentally conscious |
| | | B11 | .558 | Buying clothing keeping in mind the storage issues |
| | | B13 | .649 | Buying clothing keeping in mind the disposal and landfill issues |
| | | B14 | .538 | Considering clothing as a planned purchase |
| 2 | Mindlessness in apparel consumption | B5 | .665 | Frequently buy new clothing, even if not needed |
| | | B12 | .634 | Needing more space than for storing clothes |
| | | B15 | .616 | Comparing apparel purchase with those having higher incomes |
| | | B16 | .739 | Make conscious efforts of buying apparel products that are costlier, more fashionable |
| | | B17 | .709 | Preferring to buy luxury clothing |
| 3 | Pre-owned and shared apparel | B10 | .566 | Preferring to shop at thrift stores or second-hand clothing shops to reduce the impact of clothing on environment |
| | | B18 | .604 | Agreeing to share clothes and wearing shared clothing |
| | | B19 | .599 | Preferring to donate used clothing rather than disposing as waste |

**Table 3. Significant factors, factor loadings and Temperance statements.**

The Temperance factors that emerged significant for the Gen Z subjects in apparel consumption are depicted in Figure 3.

**Figure 3. Temperance factors significant for the respondents**

(c) **Examining significant mindset-behaviour correlations -** Mindset-behaviour mapping was done by examining correlations between Care and Temperance elements using Pearson's correlation. The aim was to identify closely related patterns of Gen Z fashion students, and comprehend 'how they think or believe and what they actually do or want to do'. Items showing considerable correlation between care (coded A) and temperance items (coded B) are depicted in Table 4. The Pearson's correlation coefficient range obtained was between 0.3 and 0.7 showing moderate positive linear relationship (Ratner, 2009) among items in the table.

| Care | Temperance |
|---|---|
| A2, A3, A7 | B1 |
| A3, A10 | B2 |
| A2, A3, A9, A10 | B3 |
| A2 | B4 |
| A18 | B6 |
| A2, A14, A16 | B7 |
| A14 | B9 |
| A13 | B18 |
| A2, A3, A7 | B1 |
| A3, A10 | B2 |
| A2, A3, A9, A10 | B3 |
| A2 | B4 |
| A18 | B6 |
| A2, A14, A16 | B7 |
| A14 | B9 |
| A13 | B18 |

**Table 4. Correlation interpretation table for the coded mindset-behaviour factors.**

This section provides the interpretation of the correlating items.

- The pre-purchase knowledge of brands' social and ethical responsibility, and the socio-environmental impacts of fashion is instrumental for Gen Z consumers in making conscious apparel purchasing decisions. They consider the environmental and social impacts of the brands
- The pre-purchase knowledge of conscious brand behaviour and fashion's impact on environment encourages Gen Z consumers to pay more for responsible fashion products.
- Knowledge of fashion brands' ethical initiatives inclines Gen Z consumers towards making changes in apparel purchasing habits and be more environmentally-conscious.
- Gen Z has a strong belief that apparel consumption, social-image and connections are closely associated. They are interested in buying high-quality clothing that last long.
- With an understanding of socio-environmental responsibility of fashion, and the importance of longevity, reuse-repurposing, Gen Z expressed interest in extending life of clothing through repair and maintenance.
- Importance of concept of longevity in clothing was leading to preference of building a capsule wardrobe of versatile and timeless pieces that can be mixed and matched.

- Gen Z understands importance of shared consumption and agrees to the practice of sharing clothes and wearing shared clothing.

The research revealed that mindfulness has unique comprehensions for Gen Z due to their psychographic and social peculiarities. While Gen Z consumers depict a pro-sustainability psychological orientation, there is a significant dis-association between Care & Temperance when it comes to behavioral orientations. They have a *Caring Mindset, but* Excessive Consumption pattern (Frazier and Sheth, 1985). Gen Z fashion students understand the socio-environmental issues and the need for responsible consumption. They possess a strong sustainability-oriented mindset in apparel consumption; however the translation from mindful thinking to mindful action is not sufficiently materializing. Research findings are in accordance to Frazier and Sheth (1985) that there exist considerable inconsistencies in attitudes and behaviour of consumers. The current research indicates a critical gap that needs to be addressed in abridging the two attributes so that Gen Z consumers make a more decisive, conscious, and responsible move towards mindful apparel consumption.

The subjects of current research represent a very miniscule percent of the entire Gen Z consumers; future research can be directed towards examining mindful mindsets and mindful behavior of other psychographic segments in Gen Z.

## Conclusion

Fashion consumption has become an over-exercised phenomenon due to changing lifestyles, backed by high aspirations, affordability and accessibility. The apparel consumption of the 'awakened' Gen Z consumers is generally described through words such as "changing", "fast" and "digital". According to McKinsey Report "The state of Fashion, 2019" fashion consumption is taking a more responsible turn with the increasing elasticity of fashion products as repair, refurbish, pre-owned, and rental models of fashion business evolve. The report indicates younger consumers 'getting woke' as their passion for environmental and social causes has continually witnessed a rise, and is visible in their shopping habits and shifts in values (McKinsey, 2019)
The research had interesting findings in context of apparel consumption mindset and behaviour of Gen Z consumers who were pursuing fashion education. This set of consumers has a psychological orientation towards the sustainability issues, and are well-aware of the socio-environmental repercussions of fashion consumption. They are aware of the ill-effects of over-consumption and quick-disposal of apparel products. However, they were found to be less pragmatically-directed towards responsible practices in apparel consumption. There was a misalignment between Care and Temperance dimensions. The study revealed the selected subjects, Gen Z (fashion students), understood and acknowledged fashion consumption induced issues, and also felt concerned. But for apparel consumption, their temperance was not aligned completely with mindset. Practicing slow fashion, thoughtful consumption and responsible disposal are challenging resolutions for this segment of consumers. They feel an urge to buy new clothing frequently, even if there was no requirement. They often compare their apparel purchase with those having higher incomes, aspire and enjoy buying costlier apparel products.

Despite having a caring mindset the Gen Z fashion students, expressed a strong penchant towards repetitive, acquisitive aspirational and impulsive apparel consumption. This behavior could be age-driven and also product-driven. Apparel consumption is a very individualistic domain where social aspects are generally given importance, just as self-concept and personality. Consuming apparels is pleasurable, and the hypercompetitive brand space along with inescapable fast fashion phenomenon makes mindful apparel consumption an arduous task. Strategic design, branding and marketing can bridge the gap between Care and Temperance, and propel the Gen Z consumers towards mindful apparel consumption.

## Annexure 1: Coded statements for Care and Temperance dimensions used in the survey

| Code | Care statements (items) |
|---|---|
| A1 | Supporting clothing brands that have environment friendly practices |
| A2 | Knowing brands in context of their social responsibility and ethical business practices |
| A3 | Researching a company's environmental and social impact before making a purchase |
| A4 | Buying products from companies that are based locally, rather than from multinational corporations |
| A5 | Recommending environmentally friendly apparel product |
| A6 | Concern about chemical usage in apparel products |
| A7 | Concern about chemical usage in apparel supply chain |
| A8 | Concern about huge amount of water usage in apparel production |
| A9 | Concern about increasing landfills due to fast disposal of apparel products |
| A10 | Concern about the use of animal-based contents in apparels |
| A11 | Concern about the working conditions of apparel production workers |
| A12 | Importance of concept of minimalistic clothing |
| A13 | Importance of the concept of shared clothing in today's times. |
| A14 | Importance of concept of longevity in clothing |
| A15 | Importance of concept of reuse-repeat in clothing |
| A16 | Importance of concept of repurposing used apparel through donation/ collection centers |
| A17 | Association of the concept of well-being with apparel |
| A18 | Association between apparels and social connections |
| A19 | Association between apparels and social image |
| A20 | Association between apparel consumption and consumers' personality |
| A21 | Feeling that fashion creates a sense of obsolescence in clothing |
| **Code** | **Temperance statements (items)** |
| B1 | Considering the environmental impact of a product when making apparel purchasing decision |
| B2 | Considering the social impact of a product when making apparel |

| | |
|---|---|
| | purchasing decision |
| B3 | Paying more for an apparel product that is environmentally friendly |
| B4 | Making changes in apparel purchasing habits to be more environmentally conscious |
| B5 | Frequently buy new clothing, even if not needed |
| B6 | Buying high-quality clothing that will last a long time |
| B7 | Extending the life of clothing by repairing and maintaining it |
| B8 | Wearing each piece of apparel in the wardrobe |
| B9 | Preferring building a capsule wardrobe of versatile and timeless pieces that can be mixed and matched |
| B10 | Preferring to shop at thrift stores or second-hand clothing shops to reduce the impact of clothing on environment |
| B11 | Buying clothing keeping in mind the storage issues |
| B12 | Needing more space than for storing clothes |
| B13 | Buying clothing keeping in mind the disposal and landfill issues |
| B14 | Considering clothing as a planned purchase |
| B15 | Comparing apparel purchase with those having higher incomes |
| B16 | Make conscious efforts of buying apparel products that are costlier, more fashionable |
| B17 | Preferring to buy luxury clothing |
| B18 | Agreeing to share clothes and wearing shared clothing |
| B19 | Preferring to donate used clothing rather than disposing as waste |
| B20 | Prefer to give used clothing for re-purposing in collection centres /NGOs, rather than disposing as waste |

5th PLATE 2023 Conference
Espoo, Finland - 31 May - 2 June 2023

# The main factors affecting the environmental sustainability of reusable packaging solutions

**Minna Salo**[(a)], **Eveliina Hylkilä**[(b)]
a) VTT Technical Research Centre of Finland, Tampere, Finland
b) VTT Technical Research Centre of Finland, Espoo, Finland

**Keywords**: Environmental sustainability, Reuse, Plastic packages, Packaging solutions.

**Abstract:** This multiple case study provides new knowledge on the environmental sustainability of reusable packaging solutions. Two different types of reusable plastic packaging solutions, reusable plastic package for takeaway food and refillable plastic package for detergents, were chosen as cases to approach the target. As a result, the main factors affecting the environmental sustainability of the reusable packaging solutions through the entire lifecycle of the packages are identified. In addition to the long list of the affecting factors, the top three factors according to our cases that have the greatest influences on the environmental sustainability are highlighted. Besides adding the academic understanding of the topic, this paper provides practical information for the companies when assessing the environmental effects of their current reusable plastic packaging solutions or when evaluating the potential of new reusable plastic packaging solutions from the environmental sustainability perspective.

## Purpose of the paper

There is a lot of discussion going on around plastic packages and their use. Policy has an important role in the discussion and development of reusable packaging solutions. Bans of single-use packaging, taxing of single-use packaging solutions and compulsory deposit systems are used in Europe as ways to influence the plastic packaging ecosystem to switch into more reusable packaging (Morawski, 2017). Customers and consumers have also become more aware and interested in environmental issues. From the perspective of the companies that are manufacturing plastic packages or to whom the packaging plays an important role in their ecosystem, it is relevant to focus their development efforts into improving the environmental performance of their activities and processes.

The emissions caused by the production of plastic packages and the damage caused by the plastic packages that end up in the nature after use are usually the first things that come to mind when talking about the environmental sustainability of plastic packages. Nevertheless, they are not the only factors affecting the environmental sustainability of the plastic packages. The entire lifecycle of the packages must be considered to assess the environmental sustainability of the reusable plastic packaging solutions (Vignali, 2016). In this study, the lifecycle phases of the packages are design of the packages, transportation, use, collection, washing and reconditioning and end of life management.

The purpose of this paper is to identify and summarize the main factors affecting the environmental sustainability of the reusable plastic packaging solutions through their lifecycle. To approach the target, we analyze the factors of two different types of reusable plastic packaging solutions: reusable plastic package for takeaway food and refillable plastic package for detergents.

## Theoretical framework

### *What is a reusable packaging solution?*

Reuse can be defined as a waste management strategy that aims to extend the product utility by slowing the material flows (Coelho et al., 2020). In the case of plastic packages, the reuse means that the packages are used again for the same purpose for which they were conceived (EU directive 2008/98/EC) and designed to accomplish within its life cycle a minimum number of trips or rotations in a system for reuse (BS EN 13429:2004). The reusable packages can be divided into refillable packages, returnable packages, and transit packages (Coelho et al., 2020).

The reusable packaging solutions can be either exclusively reused or sequentially reused. The exclusive reuse means that the reusable product is recurrently used by a single user throughout the product lifetime for the same purpose for which it was conceived. The sequential reuse means that the reusable product is used by multiple users throughout the product lifetime for the same purpose for which it was conceived. (Muranko et al., 2021).

### *Environmental sustainability of reusable packaging systems through its lifecycle*

Environmental sustainability presented by Morelli (2021) is “a condition of balance, resilience, and interconnectedness that allows human society to satisfy its needs while neither exceeding the capacity of its supporting ecosystems to continue to regenerate the services necessary to meet those needs nor by our actions diminishing biological diversity”.

The company’s environmental sustainability includes e.g., protection of the soil, waterways, and air, reduction of waste, efficient use of natural resources, conservation of biodiversity, and managing the environmental and health risks of chemicals. In addition to company’s own operations, environmental sustainability applies to the entire life cycle including the company´s partners and other stakeholders. (Harmaala and Jallinoja, 2012.) In the case of a packaging solution, to consider all the effects on the environmental sustainability, the operations done to the package throughout its lifecycle by all actors involved, must be taken into consideration.

The previous studies regarding the environmental sustainability of reusable packaging systems show that the phenomenon is complex and case specific especially when it comes to the main affecting factors. There are studies (e.g., Tua et al., 2019) showing that the biggest effects on the environmental sustainability come from the washing, mostly due to the washing and sanitation requirements (Packaging Europe 2022). For refillable packages, the biggest affects seem to be dominated by heating of the washing water (Nessi et al., 2014).

According to some other studies (e.g., Levi et al., 2011; Koskela et al., 2014), transportation seems to have the biggest effects on the environmental sustainability of reusable packages. For refill packages the effect of transportation is not that significant, since the package is used by the customer until the end-of-life, and not transported back to producer.

The previous studies (e.g., Singh et al., 2006) seem to be of the same opinion that the environmental effects decrease once the package has been reused or refilled. However, the minimum amount of reuse or refill times for a package seem to be very case specific. In a liquid detergent refill case study the results show that the container should be used at least 10-15 times, but reductions in waste creation are achieved already from 5 uses (Nessi et al., 2014). In a cosmetic case on the other hand, reusability was noted to have bigger effects than dematerialization of the package (Gatt and Refalo, 2021).

## Research Methodology

### *Research approach*

The research approach used in this study is an empirical case study. The qualitative and explorative case research approach was chosen as the best option for researching the multidimensional topic of environmental sustainability of reusable packaging solutions since it is considered appropriate to gain theoretical and empirical insight into the topic that is previously under investigated (Gummesson, 2000) and where the variables are complex and multiple (Yin, 2003).

### *Case selection and description*

The empirical study is conducted as part of an ongoing research project that is studying why and how the reuse should be done and what benefits it can create for Finnish companies in FMCG business and environment.

We have selected two cases to be studied further: reusable plastic package for take away food and refillable plastic package for detergents. These cases were selected as they represent well the different types of reusable plastic packages (Coelho at al., 2020) and reuse models (Muranko et al., 2021). The reusable plastic package for take away food is by nature sequentially used returnable package and the refillable plastic package for detergents is an exclusively used refillable package.

In both cases, the lifecycle phases of the package include:

- designing the packages
- producing the plastic material and manufacturing the packages
- distributing the packages to the retailers or restaurants
- use, reuse and refill of the packages by the consumers
- washing of the packages either at home, at the restaurant or at a washing facility before refilling or after return
- refilling or returning the packages (refill after washing, return before washing)
- end of life management

The empirical data is based on interviews with company representatives involved in both selected cases. The companies interviewed consist of companies developing, experimenting, or thinking about moving towards new reusable packaging solutions.

### *Data collection and analysis*

The empirical data is gathered by in-depth interviews with representatives from four companies. The semi-structured interviews were conducted using Microsoft Teams during January and February 2023.

During the interviews the companies were asked to talk about their motivation to the development work towards reusable packaging solutions. They were asked to describe the steps the packages go through during their lifetime and their views on what are the things in each of the step that affect the environmental sustainability of the package. The interviewees were also asked to summarize the things that have the greatest environmental effects.

Based on the interviews and previous studies regarding the subject of environmental sustainability of reusable packaging solutions, the factors that affect the environmental sustainability in each of the lifecycle phases, were collected and grouped on a table that is presented in the findings -section.

## Findings

Based on the previous studies and the interviews conducted, we formulated a summary of the main factors affecting the environmental sustainability of the reusable packaging solutions through the entire lifecycle of the packages (table 1).

| **Lifecycle phase of reusable plastic package** | **Things to consider from the environmental sustainability point of view** |
|---|---|
| Design of the packages | Are the packages fit for purpose but with as little amount of plastic/raw materials as possible and as light as possible? |
| Production of the plastic material and manufacturing of the packages | Is the machinery up to date, the energy and water consumption optimized, the renewable energy sources prioritized, and waste formation minimized? |
| Use, refill and reuse of the packages | Are the customers motivated to use the reusable or refillable packages and do they know how to use, reuse and refill them? |
| Collection/ take back of the packages | Is the collection easy enough for the customers? Is the distance to the collection point and the amount of collection points reasonable for the customers? |
| Logistics and distribution | Is the way to transport (ship, plain, truck, etc.) and the fuel choice the best options considering the weight, shape and size of the package and the driving distance? Are the routes and drives optimized? |
| Washing and reconditioning of the packages | Are the energy and water usage and the consumption of the disinfectant minimized? |
| End of life management | Are the packages reused many times enough before the end of life? What is the chosen waste management strategy (recycling, incineration, landfilling)? |

**Table 1. The main factors affecting the environmental sustainability of the reusable plastic packages.**

In our cases, top three factors affecting the environmental sustainability were washing, raw material production and logistics. First, washing was seen to have great environmental effects in both cases. According to the interviews, it can cause up to 50 % of the environmental load of the reusable food packages. Heating of the water is the biggest influencer since especially in the case of food package, the washing temperature should be high due to the hygienic issues. The washing times and used chemicals also cause some of the environmental effects. Second, the raw material of the packages is plastic so as a fossil based raw material, its´ production causes lot of environmental load. Third, what comes to the logistics, the weight of the package was seen to have the biggest effect on the environmental burden. The environmental effects of logistics also depend on the fuel used, the driving distances and the volume of the drives. The top three factors affecting the environmental sustainability of reusable packaging solutions in case of reusable plastic package for takeaway food and in case of refillable plastic package for detergents are shown in figure 1.

**Figure 1. The top three factors affecting the environmental sustainability of reusable packaging solutions in case of reusable plastic package for takeaway food and in case of refillable plastic package for detergents.**

Since our cases are consumer products, it is also very important also from the environmental perspective that the reusable and refillable packages are as easy and functioning that the consumers are willing to use them. Another thing that is important in the eyes of environmental sustainability and yet not clear is how many reuse times the packages last. Defining if the package is still usable considering e.g., its surface damages, colour changes and microbiological issues, affects the amount of reuse times especially in the case of reusable plastic package for takeaway food.

The packaging ultimately has a limited effect on the total environmental sustainability of the product. Often the biggest effects of the total environmental burden are caused by the manufacturing of the product itself. For example, in the case of refillable detergent packages, the production of the detergent ingredients appears to cause ca. 65 % of the total environmental effects (Koehler and Wildbolz, 2014). Packaging solutions and their environmental effects are still important to pay attention to since it is not possible to get rid of all packages because they are crucial for transportation. When the system is transitioning from single-use to reuse, it is noteworthy that new challenges can rise elsewhere, e.g. in the refill system's hygiene or chemical safety.

## Conclusions

This paper provides new understanding on the multiple factors affecting the environmental sustainability of reusable packaging solutions. As a main result, we formulated a summary of the main factors affecting the environmental sustainability of the reusable packaging solutions through the entire lifetime of the packages. There are things to be considered in every lifecycle phase that effect the environmental burden of the packages. In our cases, top three factors that have the greatest effects on the environmental sustainability were washing, raw material production and logistics. In the case of reuse, the washing was seen to have a major effect on the environmental sustainability followed by raw materials production and logistics whereas in the case of refill the raw materials production was the main factor causing most of the environmental effects followed by washing and logistics.

In addition to the academic need to increase understanding on the topic, the paper provides practical information for the companies when assessing the environmental effects of their current reusable plastic packaging solutions or when evaluating the potential of new reusable plastic packaging solutions from the environmental sustainability perspective.

## Acknowledgments

This study was carried out as part of the 4EverPack research project funded by Business Finland. The authors acknowledge project research partners and the companies who were willing to open their cases for research.

# Assessing Product Circularity in Practice: Insights from Industry

**Lilian Sanchez-Moreno[a], Martin Charter[a]**
a) University for the Creative Arts, United Kingdom

**Keywords**: Circular Economy; Eco-design; Product Circularity; Design and Development; Lifecycle Sustainability Assessment; Circularity metrics and indicators.

**Abstract**: The use of the concept of 'circularity' within government, policy, industry, and academia, has grown exponentially in the last decade. As part of the European Commission's Horizon 2020 funded project, ORIENTING, The Centre for Sustainable Design ® at the University for the Creative Arts conducted 21 in-depth qualitative interviews with companies that claimed to have a core circular economy business strategy. The data collected from the interviews was analyzed using a thematic coding methodology to 1) gain insights into how product circularity (PC) is understood by industry, PC strategies currently being implemented across various sectors; 2) identify barriers for implementation that can enable further discussions for theoretical and conceptual innovations for remanufacturing, reuse, refurbish and repair and new ways for production and consumption, and 3) contribute to the development of methodologies and tools for measuring product circularity beyond recycled inflows and outflows. A key finding was the lack of harmonization of the concept of PC and CE more generally across different sectors. Moreover, to date, the development of methodologies that seek to quantitively assess PC performance for internal decision making and external communications, have focused primarily on assessing the use of recycled material inflows and outflows; thus, positioning circularity as synonymous to recycling. Conversely, measuring use phase related PC issues e.g., repair, reuse, etc. is still in the early stages due to a lack of data on customer use by companies.

## Introduction

The use of the concept of Circular Economy (CE) within government, policy, industry, and academia has grown exponentially in the last decade. The CE concept builds on multiple schools of thought, some of which date back to the 1960s, including: industrial ecology, industrial symbiosis, performance economy, biomimicry, cradle to cradle, blue economy, regenerative design, and natural capitalism [1]. CE became mainstream because of the policy attention given to it by the European Commission's (EC) 1st Circular Economy Action Plan launched in December 2015 (CEAP 1.0). Additionally, the Ellen MacArthur Foundation (EMF) has played an important role in raising awareness and in engaging business [2].

At present there is no internationally agreed definition of the CE concept, as shown by Kirchherr et al. (2017 [3]), which identified 114 circular economy definitions in different sources of literature. This proliferation of CE conceptualizations constitutes a serious challenge to policy makers, business and researchers working on this topic. In this regard, ISO is working on a consensus-based definition of CE within ISO TC323 which will be an important step towards increased understanding.[1] Aligned to this, there is growing interest in the measurement of CE at various levels (e.g., products, organisations, regions). However, while currently there exists a plethora of PC metrics, indicators, and tools to measure circularity [2] as indicated within the ORIENTING report, *Critical Evaluation of*

[1] As of November 2022, CE has been defined within the work of ISO TC323 as: "A state of a specified system, organization, product or process where resource flows and values are maintained whilst benefiting sustainable development and approach to promote the responsible and cyclical use of resources."

[2] For example, the Ellen MacArthur's Material Circularity Indicator (MCI) and the WBCSD's Circularity Transition Indicator (CTI).

*Material Criticality and Product-Related Circularity Approaches*, the focus is primarily at an organization level rather than at a product level [4]. Moreover, the awareness and usage of PC indicators, metrics and tools by industry remains limited. In this context, the research presented in this paper aimed to gain insight into if and how PC is understood, implemented, and measured by industry. To do this, 21 in-depth interviews were completed.

## Methodology

The research employed semi-structured qualitative interviews with a blend of closed and open-ended questions. Qualitative interviews were used to facilitate a 'learning approach' with the interviewees, allowing for the recognition of emerging themes and patterns related to the research topic. The pilot and full interviews were planned for 45 minutes up to 1 hour and were divided into two main topics: 1) General questions to assess the interviewee's level of decision making related to PC and 2) PC specific questions, to probe into more detailed aspects related to measurements, metrics, indicators and the use of eco-design strategies and tools.

Four CE expert interviews helped scope, frame, and check the content of questionnaire and acted as pilot interviews. The participants for the main interviews were selected based on the authors knowledge of companies as being actively developing CE activities. Building on the learnings from the 4 CE expert interviews, the following research strategy was developed: for large companies that have various Business Units and corporate functions ('line and branch'), the aim was to initially interview corporate Sustainability Directors to provide an overview of PC issues across the Business Units. For start-ups and micro, small and medium enterprises (MSME's) the aim was to interview the Founder/Managing Director (MD) as responsibility for sustainability and PC related issues within MSME's are likely to be carried out by these functions.

Prior to each interview, background research was conducted by reviewing the company's sustainability reports and website. The interviews were then recorded and transcribed. At 21 interviews, no further PC related topics had emerged for more than 2 consecutive interviews. It was then agreed by UCA and ORIENTING leadership that interviews would be capped at 21. **Table 1** shows the industry sectors interviewed, as well as product categorization, company size, geographic location, and PC awareness level.

| No. | Industry Sector | Size | Product Category |
|---|---|---|---|
| 1 | Fashion/Apparel | SME | Final |
| 2 | Footwear | Start-up | Final |
| 3 | Infrastructure | Start-up | Hybrid |
| 4 | Whitegoods | Multinational | Final |
| 5 | Toys | Multinational | Final |
| 6 | Automotive | Multinational | Final |
| 7 | Outdoor footwear | SME | Final |
| 8 | Textiles | Start-up | Intermediate |
| 9 | Furniture | SME | Final |
| 10 | Hardware & Software | Multinational | Final |
| 11 | Engineering /Aerospace | Multinational | Final |
| 12 | Fashion | Start-up | Hybrid |
| 13 | Footwear | Start-up | Final |
| 14 | Flooring | Multinational | Final |
| 15 | Automotive | Multinational | Final |
| 16 | Fashion/Apparel | Multinational | Final |
| 17 | Consumer goods | Multinational | Final |
| 18 | Software & Hardware | Multinational | Final |
| 19 | Textile | Start-up | Intermediate |
| 20 | Construction | Multinational | Intermediate |
| 21 | Automotive | Multinational | Final |

**Table 1.** Sample Information

### *Analysis of Data: Thematic Coding*

The data from the 21 interviews was analysed using thematic coding, which consisted of categorising and assigning different values to the key themes and topics that emerged from each interview. Labels were assigned to words or phrases that represented important and recurring themes related to PC issues. While the interview questionnaire was adapted and improved after each interview, the core questions were maintained for comparability. The interviews were initially transcribed, whilst simultaneously adding notes related to the themes and topics that were repeated or emphasised throughout the interview. Subsequently the key themes were categorised and arranged to produce a summary which was discussed between the authors to identify further areas of enquiry that were addressed with follow-up questions via email and/or in subsequent interviews.

### *Multilevel Awareness Descriptors*

Aligned to the thematic coding analysis, a multilevel PC awareness descriptor was developed based on the ZBIA model which describes levels of awareness that range from zero to basic, intermediate, and advanced [5]. Additionally, the WBCSD's 2018 report, 'Circular Metrics Landscape Analysis' [3] was used to support the development of the awareness descriptor shown in **Table 2**. It is pertinent to highlight that from the ZBIA model, level "zero" was removed as the selection of the interviewed companies was based on them being on a CE journey.

| Circularity Strategy Stage | Description |
|---|---|
| Level 1/ *Basic* | Company has started to research, explore CE strategies but has not yet defined a product and/or company strategy. 1-2 years' experience within the remit of circularity. |
| Level 2/ *Intermediate* | Company has started to implement CE strategies but has not yet integrated CE indicators and metrics. 2-3 years' experience within the remit of circularity. |
| Level 3/ *Advanced* | CE trailblazers or 'advanced' CE companies with 4+ years' experience in developing company and product level CE strategy and has started to implement some CE indicators and metrics. |

**Table 2. Multilevel Awareness Descriptor (Source: authors' adaptation of WBCSD 2018 report)**

As a result of assigning awareness levels to each participant, needs and requirements related to the implementation of PC strategies, metrics and indicators were identified per level.

## Results

### *Defining Circularity*

The interview findings suggest that an understanding of how to implement circularity and what this entails is fragmented. In this sense, the concept of CE at a product level varies depending on the type of product and industry. At a product level, the most common focus areas for addressing circularity, are the use of recycled content and biobased materials, along with ensuring that product components can be easily recovered and recycled through eco-design strategies such as design for product life extension that includes standardization, compatibility, and design for disassembly (Appendix A).

It is pertinent to highlight that few companies interviewed appeared to use the term eco-design. This was surprising to the authors as many of the companies had previously been actively engaged in ecodesign. The responses from the interviewees also indicated that whilst CE and within it, PC was seen as part of the companies' sustainability strategies, CE activities were somewhat compartmentalized perhaps indicating "newness" of CE and PC in many organisations. In addition, where eco-design was recognized as a practice in companies, PC aspects were considered separately to eco-design, despite being inherently aligned with eco-design strategies.

For interviewees with 'basic' and 'intermediate' PC awareness levels, circularity appeared to be mainly used to refer to the use of recycled materials. Additionally, the interviews revealed the emergence of new concepts and terminology such as circular by design' and 'circular-ready design', which are synonymous with specific design strategies and products that are aligned with Design for Material Sourcing, Design for Manufacturing and Design End-of-life (Appendix A). A potential consequence of organisations' directly associating circularity with the use of recycled material and design for disassembly, is that other PC strategies such as re-use and repair remain excluded from CE discourses amongst the interviewed companies. In turn, the exclusion of such strategies from industry discourse can potentially lead to some companies, particularly MSME's, to remain unaware of the existence of PC strategies that related to the use phase of the lifecycle.

However, some of the more 'advanced' companies' as per **Table 1** have started to move beyond a focus on recycling as a means towards circularity by differentiating for example, '*Material sustainability*

[3] The WBCSD's report is based on 38 company interviews and the assessment of 140 sustainability reports, which highlights three CE strategy levels.

*initiatives'*[4], from *'circularity initiatives'*[5] and appear to be assigning a hierarchy to circularity strategies. In this context, 9 of the companies categorized as level 3 or 'advanced', indicated a shift in their circularity ambitions towards product and part reuse through designing for repair, maintenance, and upgradability as well as exploring product service systems (PSS) such as 'pay-per-use', 'product leasing' and 'take back' schemes.

This highlights the differing understanding of PC amongst interviewees as it shows that the precise definition of the concept varies from one company and product to another, and perhaps based on the level of awareness/understanding/experience of PC/and CE more generally.

The findings above highlighted some of the concepts and nuances that are emerging within industry when defining circularity. Regarding the development of PC assessments, findings highlighted the importance of considering how circularity is interpreted from a myriad of perspectives, which will ultimately affect the approach adopted for measuring PC.

The following section aims to offer insight into how companies are currently measuring PC or considering PC measurements and indicators based on the available PC tools and methods.

### *Measuring Circularity*

Interviewees were asked about the specific use of The Ellen MacArthur Foundation's MCI (2021) and the WBCSD's CTI tool.[6] From the 21 companies interviewed only 2 companies claimed to measure circularity at a product or business level using the EMF's MCI, whilst no participant mentioned the use of the WBCSD's CTI tool.[7] Therefore 19 companies interviewed were not using these or any other PC tools to support the development of their circularity strategy. One of the companies identified as using the EMF's MCI, [Participant 10] stated that the circularity percentage highlighted in their annual sustainability report refers to the company's '*total annual product and packaging content by weight, that will come from recycled and renewable materials and reused products and parts'.* As this company has been classified as 'advanced' in terms of PC strategies, this highlights that for companies with this level of awareness, the focus of PC measurement remains on quantifying inflows of recycled content or the use of biobased materials within a product and outflows through recovery percentages. This is likely to be due to companies perceiving this is what they can pragmatically control, measure and report; with the use phase often seen as outside their control in current business models. Nonetheless, as [Participant 15] indicated, some companies are seeking to explore the feasibility of measuring PC beyond the use and recovery of recycled content by developing *'KPI's for circularity'* that could potentially include indicators such reuse rates through take-back schemes or repair and refurbishment, as well as methods for quantifying disassembly times in relation to economic viability.

[4] 'Sustainable materials initiative' in the context of the interview appears to refer to strategies that focus specifically on reducing the environmental impact of a products materials. As per the eco-design checklist presented in Appendix A, this strategy focuses primarily on 'Design for Material Sourcing' that includes the reduction of weight and volume of a product, increase use of recycled materials to replace virgin materials, the elimination of hazardous substances and the use of materials with for example, lower embodied energy and/or water, which do not necessarily lead to PC.

[5] 'Circularity initiative' appears to focus more on strategies that enable material and product extension at the 'end-use phase' through 'Design for Manufacture and Assembly' and 'Design for Use (including installation, maintenance and repair)' as per Appendix A. These eco-design strategies for example avoid designs that are detrimental to material recycling, reduce the amount of residual waste generated within their D&D process, avoid designs that are detrimental to reuse and enable design for disassembly to ease repair, recycle and reuse.

[6] The EMF's MCI and WBCSD's CTI were included in the questionnaire in alignment to the 2 PC indicators selected for ORIENTING project.

[7] The numbers presented here are based on the interviewee's awareness of the use of either the EMF's MCI or the WBCSD's CTI 2.0 within their company and background research into company sustainability reports. Since most of the interviewees formed part of D&D units, it is possible that more companies are looking into these PC measurements and indicators, but this information is held elsewhere within the company.

In addition, companies appear to be '*working on how to integrate circularity into design and development, while figuring out where the boundaries are for measuring circularity.'* In this sense, the boundaries for circularity appear to be driven by product type and industry sector. For example, a toy manufacturer that designs for longevity where their products are rarely recycled (as there is significant reuse of the products), would have to assess the trade-offs associated with replacing the current materials used with recycled or bio-based materials, which would then have to be measured during the *use* phase. Aligned to the extension of the system boundaries, [Participant 5] had started to explore ways to incorporate the *use* phase by conducting '*internal investigations to gain insight into what happens to the product once it has left the manufacturer'* and what influence it might bring to the *use* phase through design decisions that 'nudge' or 'educate' the user to make decisions that have a lower environmental impact during the use phase.

Other companies appear to be measuring the recycled content that is reintroduced within their production line as an indicator of a products' circularity. However, due to the nature of some businesses, measuring the inflow of recycled content within a product is challenging for some companies as they do not have access to this data. Considering the current work being undertaken by companies at different circularity readiness stages and/or levels of awareness, it is important to promote the importance of a multilevel approach within sustainability assessment methodologies. In this sense, companies classified as zero to basic might start by measuring the inflow of recycled content as an initial step toward implementing PC. While the more 'advanced' companies that have started to explore PC considerations within the use phase, will potentially be interested in measuring beyond the use of recycled material and towards a 'cradle to cradle' perspective. A further issue identified was that the extensive number of frameworks, assessment tools and methodologies available often provide limited guidance for users about the benefits of one over the other. Based on the myriad of internal tools being used by interviewees for assessing sustainability concerns, and within this PC, a key learning from this section is that there is a need for the development of sustainability assessments to be flexible and adaptable to existing industry processes. However, to measure PC, organizations will first need to overcome barriers associated with the implementation of PC strategies, some of which are presented in the following section.

### *Identified Barriers for the Implementation of PC*

A key barrier identified for the implementation of PC, was the siloed nature of communication across business functions. It was identified that connections between the various business functions (e.g., environmental, CSR, supply chain, marketing…) and those directly or indirectly involved in the design and development (D&D) process, depends on the culture of the company and individual company policies. For example, [Participant 15] indicated that '*there is no natural connection between [business functions], it is something I established because it is within my job and my network that I'm going to bring these people in'*. Thus, as recognised in the literature, it is key to establish a common language and a shared vision of PC, which can ultimately assist in communicating PC strategies across an organisation's various business functions. This is seen as fundamental for the implementation of eco-design and PC [6].

Moreover, the costs associated with material substitution, development of new infrastructure and business models was also mentioned by most interviewees as a barrier. For some of the smaller companies interviewed, the scalability of PC strategies such as the production of materials utilising bi-products from other industries appears to also be an issue of concern. With regards to material substitution, it is not only cost that represents a barrier, but also maintaining product functionality, performance and consumer expectations whilst using an alternative material such as recycled PET or biobased materials.

Finally, a key area that was also mentioned by the interviewees, is the aesthetics of sustainability and how these need to align to customer/market demands. This includes consumer willingness to accept aesthetic/external product changes associated with PC interventions such as the 'feel' or 'look' of recycled materials or plant-based materials e.g., 'vegan leathers'. Some of the companies interviewed are addressing concerns related to the potential impact of PC strategies on a product's aesthetics by, using recycled materials only on non-consumer facing product surfaces. If the barriers to implementing PC are to be overcome, it is recommended that PC assessment methodologies and tools address how to effectively communicate and present results across business functions. Additionally, strategies should aim to educate/raise awareness of sustainability decisions being made that may potentially have an impact on the product aesthetics and price to increase market acceptability.

## Conclusions

Drawing on the findings documented in ORIENTING's *Critical Evaluation of Material Criticality and Product-Related Circularity Approaches* report [4], which identified and evaluated over 100 methods and tools that aim to measure circularity, this paper shows how companies remain in the very early stages of PC implementation and measurement. Moreover, the research highlights that there is a disconnect between existing literature and research, and the awareness, and understanding of PC indicators and metrics within industry. The interviews further showed that not only are companies not measuring PC, but that they are unaware of existing methods and tools available to them. While those that are aware of existing tools, have highlighted that they do not find they meet their product/industry requirements, or address the goal of assessing a circularity strategy within the use phase. As such, this research sheds light on key areas that require attention for achieving an effective transition towards the CE at a product level and the need to bridge the gap between academia, policy, and industry requirements. Below is a summary of the key findings:

It is important to promote the importance of a multilevel approach within sustainability assessment methodologies. In this context, UCA has developed a PC starter checklist to assist relevant stakeholders in starting their product circularity journey. The PC starter is currently being piloted by 2 case studies.

Methodology and tool development should offer guidance for adapting PC measurements and indicators to meet industry specific requirements or at a basic/entry-level, help companies to define a starting point for their PC journey.

PC assessments should be flexible and adaptable to existing industry processes.

There is a need for increased focus on consumer's needs and requirements to effectively participate in the CE.

The dilemma between accessing user data whilst simultaneously complying with data privacy needs to be tackled, as this is key for including the use phase within PC indicators and metrics.

It is also recommended that PC assessment methodologies and tools address how to effectively communicate results across business functions.

Lastly, if the barriers to implementing PC are to be overcome, focus is also needed in educating and raising awareness of the impact of PC strategies vis a vis product aesthetics and price to increase market acceptability.

## Acknowledgments

This research was funded by the European Union's Horizon 2020 Research and Innovation programme under grant agreement No. 958231. The authors would like to thank the interviewees for their time and valuable input provided for this research. Additionally, the authors thank ORIENTING partners for their feedback and discussions on earlier versions of this research.

# Introducing Feedstock-Material-Product Combinations: Revaluing Wastewater Into Bio-composite Materials And Meaningful Applications

**Marita Sauerwein[(a,b)], Peter R. Mooij[(a,b)], Stephen J. Picken[(b)], Mark C. M. van Loosdrecht[(b)]**
a) AMS Institute, Amsterdam, The Netherlands
b) Delft University of Technology, Delft, The Netherlands

**Keywords**: Biobased feedstock; Biobased and wastebased materials; Circular economy; Product design; Bio-composite.

**Abstract**: The reuse of waste streams is one of the key principles of a circular economy. Wastewater is a significant waste stream in urban regions, yet largely unexplored for material and product development. We therefore developed a bio-composite using wastewater as feedstock. Consequently, this bio-composite relies on sustainable resources and is biodegradable. As such it is a relevant material for a circular economy. However, a material only becomes of value when suitable applications and end of life options are found. The feedstock, material and product level all influence each other and hence we propose to iteratively consider them during development. The goal of this paper is therefore twofold; we introduce *Feedstock – Material – Product combination* (FMP-combination) to approach renewable material development in a circular economy, and we introduce Re-plex, as a result of value appreciation of wastewater and example of an FMP-combination. With the development of Re-plex, we prove the value recovery of a major organic waste stream. Due to the iterative process between feedstock, material and product level, we could extend the lifetime of an organic waste stream into a high value material for which interesting applications were found with market parties, i.e. façade panels for the building industry and 3D structures for nature restoration in aquatic settings. From this we conclude that approaching the development of a biobased material for a circular economy as an FMP-combinations places the material in a broader context. This helps to steer the optimization process as it gives insight into which properties are required to meet the envisioned product lifetime and high value recovery.

## Introduction

The reuse of waste streams is one of the key principles of a circular economy (MacArthur, 2013). Waste streams should therefore be considered when developing materials and products for a circular economy (Velenturf & Purnell, 2021). Wastewater is a significant, yet largely unexplored, waste stream in urban regions for material and product development. Currently, wastewater is used for energy production via production of biogas, but hardly for material and product development. This is a missed opportunity, because products and materials are valued higher in the biomass value pyramid (figure 1) and are therefore preferred over applications lower in the pyramid (Van Der Hoek et al., 2016).

We developed a bio-composite of which the main components originate from wastewater. Composites are valuable materials, because they offer interesting material properties (e.g. strong, stiff, and light weight). A composite consists of fibres (e.g. glass-, carbon-, or natural-fibres) and a resin that binds these fibres together (e.g. epoxy, polyester). However, fossil-based composites are difficult to reuse or recycle (Joustra et al., 2021), and as such have a poor environmental performance in terms of end-of-life strategies. On the other hand, fully biobased composites can

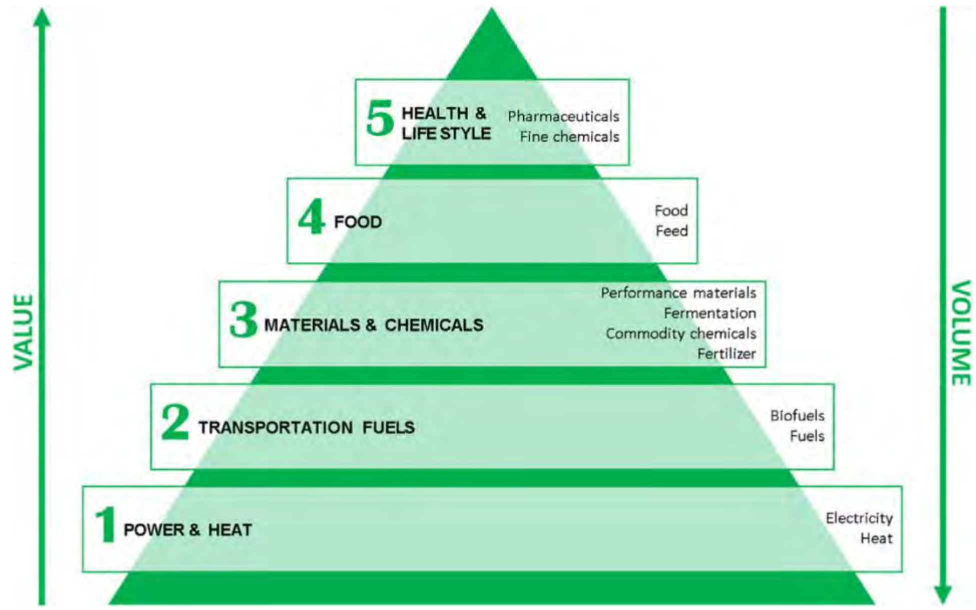

**Figure 1. Biomass value pyramid @Van Der Hoek et al., 2016.**

biodegrade, hence providing a sustainable end-of-life option; the composite serves as feedstock for (microbial) organisms and re-enters the biological cycle (Bakker & Balkenende, 2021).
The feedstock of our bio-composite relies on sustainable resources and as such is relevant for a circular economy. However, a material really becomes of value when suitable applications are found. Furthermore, in a circular economy materials and products should be preserved at the highest value for as long as possible (Korhonen et al., 2018). Since material development and product design influence each other on end-of-life scenarios, they should be considered together. A product for example can only be recycled when it is made of recyclable materials, but in addition the product should be designed in in such a way that the materials can actually be harvested for recycling.

In other words, when developing biobased materials for a circular economy both feedstock, material and product should be considered. In this paper we therefore propose to approach development in such a way that

**Figure 2. Linear relationship between feedstock, material and product level.**

feedstock, material and product development strongly interact. The goal of this paper as such is twofold; we introduce *Feedstock – Material – Product combination* (FMP-combination) to approach renewable material development in a circular economy, and we introduce Re-plex, as a result of value appreciation of wastewater and example of an FMP-combination.

## FMP-combination

In traditional material development feedstock, material and product have a linear relationship as shown in figure 2. However, in a circular economy, these levels strongly depend on each

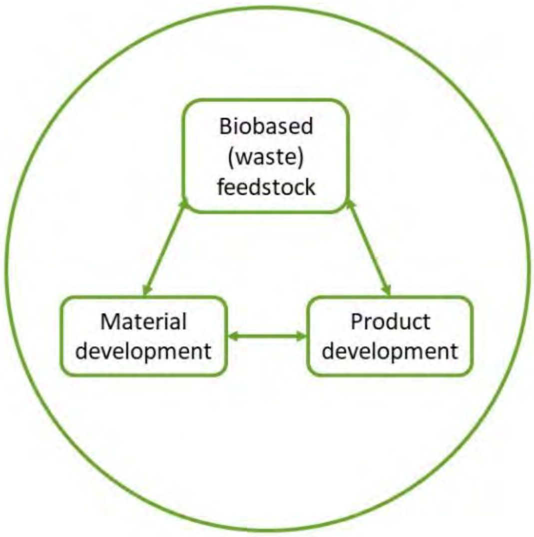

**Figure 3. feedstock-material-product combinations (FMP combinations).**

other when aiming for high value recovery. We propose to iteratively connect feedstock, material and product, so that all stages can inform each other from early development onwards. Moreover, we should not develop materials and/or products, but approach new development as Feedstock – Material – Product combination (FMP-combinations). Figure 3 graphically represent this interdependency.

Identifying a suitable FMP-combination depends on many factors, e.g. size of the biobased (waste) stream, material characteristics and market interest for possible applications. We therefore propose to move back and forth between the different levels from early development onwards so that all levels inform each other and are closely connected.

## Materials and Methods

In this paper we approached the development of Re-plex as an FMP-combination. The focus in the development process thus lays on wastewater as feedstock, a biocomposite as material, and suitable applications as products. In this case, we found two applications, i.e. a nature-restoration structure, and a façade panel. The materials and methods corresponding to feedstock, material and product are described below.

### *Feedstock level*

All components of Re-plex are biobased and the main ingredients, i.e. the fibres and binder, originate from wastewater. For the fibres we opted for cellulose-fibres from retrieved toilet paper. For the resin we used Kaumera Nereda® Gum (in short: Kaumera), a soluble biopolymer produced in the Nereda® wastewater treatment process. In this wastewater treatment process bacteria produce Kaumera while cleaning of the wastewater. (Pronk et al., 2015). Kaumera has many interesting properties, including the ability to bind fibres together (Felz, 2019). The potential Kaumera production at around 5 kg per person per year is significant, as it would constitute about 10 – 20% of total plastics use. All components of Re-plex and their function are shown in table 1.

| Component | Role |
|---|---|
| Kaumera | Binder |
| Recell | Fibre |
| Powder from plant source | Filler |
| Citric acid | Additive for cross-linking[1] |
| Glycerol | Additive as plasticizer |
| Tap water | Additive for flow |

**Table 1. Ingredients of Re-plex.**

### *Material level*

On a material level we defined the formulation, production and properties of the material. The exact composition of the components and the production process were found from experimentation and trial-and error optimisation. To gain understanding of the material properties both technical and experimental tests were performed:

- *Technical tests*
  To obtain the tensile strength and modulus of Re-plex a three-point bending test was performed according to ISO 14125 with three samples. Fire resistance was tested by performing a flammability test during which a sample was exposed to a flame for 12 minutes. The biodegradability of Re-plex in water was tested by placing samples in salt, tap and canal water for seven weeks. These samples were observed and measured.
- *Experimental test*
  The Ma2E4 toolkit was performed to obtain an understanding of the experiential characteristics of Re-plex (Camere & Karana, 2018). With this toolkit the material is tested on its performative, sensorial, interpretive, and affective qualities. Thirteen respondents tested the experiential characteristics of Re-plex (female: 9 male: 4; age mean 34; Artistic/design background: 5)

### *Product level*

On a product level we sought for suitable applications and used prototyping and field test to further develop and validate these applications. This was an iterative and creative process for which the first results of material

[1] Crosslinking is a process to form chemical bonds to join two polymer chains together. For Re-plex cross-linking is applied to make the material water-resistant and stronger

properties were used. The results from the technical and experimental studies, as well as material samples, served as an input for brainstorm sessions. Several brainstorm sessions were held with different groups and a variety of participants ranging from backgrounds in building, construction, design, nature restoration, and municipality.

During prototyping samples of the material were made to test certain aspects. These prototypes ranged from simple samples to test the production process to prototypes that reflect the foreseen application. For Re-plex we initially made small beams and flat sheets and concluded with 3D tiles and a full prototype for field testing.

For the field test, the prototypes were placed in the context of the envisioned application, i.e. for nature restoration and façade cladding. Re-plex was tested in several environments based on these applications. During these tests several parameters were monitored based on observation.

## Results

The results are depicted on feedstock, material and product level.

### *Feedstock level*

The main result on feedstock level is the need for washing Kaumera. During the development process we found out that high concentrations of salts, resulting from the Kaumera extraction process, were hindering the material development. Samples with washed Kaumera performed better in field test than non-washed samples (also see below).

### *Material level*

In figure 4 a sample is shown of the bio-composite Re-plex.

| | Ingredients | Amount % |
|---|---|---|
| Binder | Kaumera | 33 |
| Fibre | Recell | 25 |
| Filler | Powder from plant source | 5 |
| Additive | Citric acid | 27 |
| | Glycerol | 6 |
| | Tap water | 4 |

**Table 2. Ratio between components for Re-plex.**

**Figure 4. Re-plex bio-composite sample.**

### *Composition and production*

Table 2 gives an overview of the ratio between the components.

Re-plex is produced with hot pressing. During this production process the material is placed in a mould which is heated and closed under pressure. Pressure and heat are maintained until the material is cured. Temperature and time for curing Re-plex were determined by experimentation. The production process consists of several steps:

1. Resin and dough preparation
   First a resin is prepared from Kaumera, citric acid, glycerol and tap water by kneading these ingredients for several hours at room temperature. Subsequently Recell and the organic powder are added to the resin and kneaded at 90°C to obtain the dough. This dough is placed in the mould.

2. Hot pressing
   The mold is pressed at 140 °C and at 150 kN for 10 minutes. Subsequently the pressure is released to degasse the sample and repressed at 20-30 kN for 1.5 hours to cure.

### *Technical material properties*

In table 3 the values for the tensile strength and modulus are given as a result of the three-point bending test. The table also shows these values for other comparable biocomposites. The tensile strength is still low, but the modulus is in the higher range.

The fire test showed good performance of the material when exposed to a butane flame. During the first two minutes some enlarged

| Material | Tensile strength (MPa) | Modulus (GPa) | Strain (%) | Reference |
|---|---|---|---|---|
| Re-plex | 7 | 2.7 | 0.3 | |
| PHB+ sawdust | 21 | 3 | | (Cinelli et al., 2019) |
| PHA+ cellulose micro fibres | 23 | 0.9 | | (Cinelli et al., 2019) |
| PLA+ banana | 18.5 | 1.5 | | (Rajeshkumar et al., 2021) |
| PLA+ coir | 14 | 4.4 | | (Rajeshkumar et al., 2021) |

**Table 3. Tensile strength and modulus for several biocomposites.**

flames were visible. Afterwards, charring of the sample started. During the test, no dripping or visible fumes occurred. At minute twelve, about 50% of the sample was charred and had broken off the entire sample (figure 5).

**Figure 5. Fire resistance test**

For the biodegradability test, the material kept its shape for seven weeks. The weight of the samples increased after submersion and stayed constant afterwards. Algae grow appeared on the canal water samples and for the tap and saltwater tests fungus formations appeared in the water (figure 6). The weight measurements show that the material does not degrade immediately, but the microbiological activity indicate that it will biodegrade eventually.

**Figure 6. Fungus growth in tap and salt water respectively and algae growth on sample from canal water.**

*Experimental material properties*
The outcomes of the experimental test can be summarized as follows:

- On a performative level most people picked the material up and smelled it;
- On a sensorial level people found it a rigid, but weak material, with an irregular surface.
- On the affective level the smell and weakness were named as disturbing qualities. The material broke much easier than the participants had expected. On the other hand, they felt curious about the unfamiliarity of the material.
- On an interpretive level Re-plex was judged futuristic. Furthermore, Re-plex look and feel were judged as natural, due to its irregular surface and warm and smooth touch. These qualities were appreciated. Also, the story behind the material (i.e. being a material from wastewater) increased the positive appreciation of the material.

*Product level*
The biodegradability, fire- and water-resistance, and good strength are distinctive properties of Re-plex. With these in mind the brainstorm sessions yielded two initial applications for further testing, i.e. nature restoration in aquatic settings and façade cladding. Both applications were tested and developed in collaboration with a market party. Figure 7 gives an overview of the design and tests.

When producing the prototypes for the field tests it became clear that the brittleness of the material is a serious problem. Many of the beams for the 3D structure for nature restoration already broke during assembly, therefore less test environments could be tested than planned for. For the façade panels, the initial plan was to create 3D structured tiles. However, we were unable to structurally release these from the mould. Therefore flat and smaller samples were created.

Furthermore we could integrate an improved version of Kaumera, i.e. washed Kaumera, in this field test as well (also see Feedstock level).

| | Nature restoration | Façade panels |
|---|---|---|
| Design |  |  |
| Description | 3D structure to support young plant growth in an aquatic environments. As soon as the plants take root, after 2-3 years, the support structure becomes redundant and should degrade without harming the environment. | Tiles for façade cladding to support biobased building. The tiles are made with washed and unwashed Kaumera and coated with Linseed oil and 2KPU Varnish. |
| Based on material properties | o Water resistance<br>o Biodegradability<br>o Strength | o Water resistance<br>o Fire resistance<br>o Strength |
| Test environment | o Dutch salt water (Voordelta)<br>o Dutch fresh water (Vechtplassen) | o Living lab location Amsterdam (Bajeskwartier) |
| Test parameters | o Speed<br>o Modus of biodegradation | Influence of weather on<br>o Structural (degradation) performance<br>o Aesthetic (changing colour) performance |

**Figure 7. Overview of design and tests for field tests.**

*Field tests*

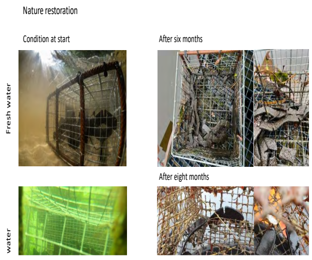
The field tests are still ongoing and the samples are under observation. Figure 8 and 9 give an overview of the samples at the start and after respectively 6-8 months and one month. The samples for nature restoration are broken after 6-8 months, but they kept their shape. In fresh water, algae growth appeared on the surface and in salt water, the samples eroded.

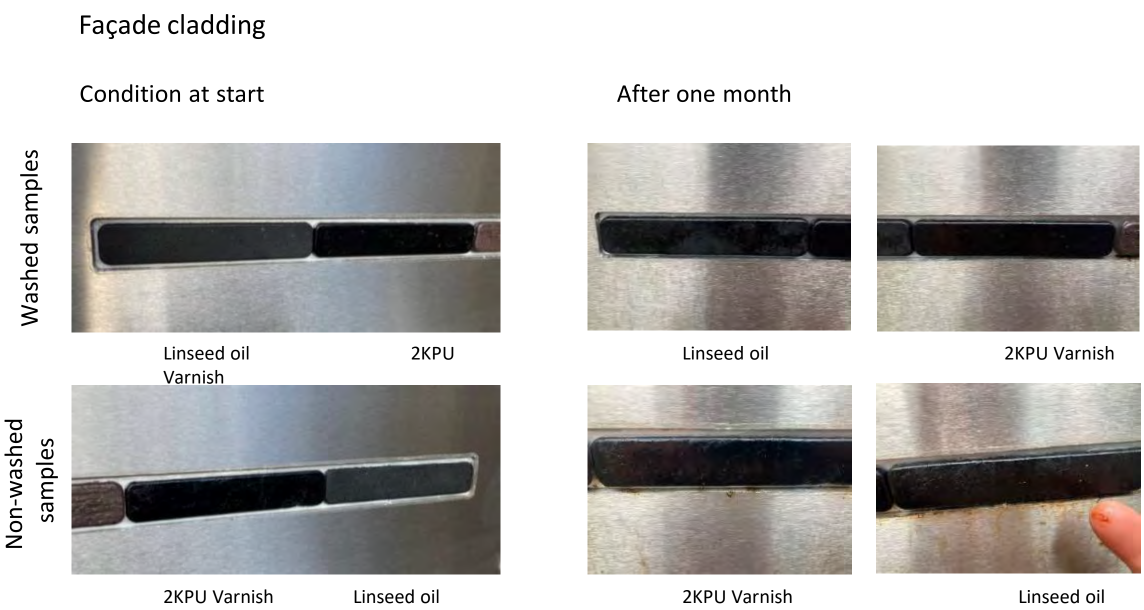
The façade panels show a significant difference between the washed and unwashed samples after one month (figure 9). The non-washed samples started leaking and the sample coated with linseed oil leaves traces when touching. On the contrary, the washed samples with both the linseed oil and 2KPU coating are still in rather good shape. Observation after one month took place after rainy weather and a notable smell was detected for all samples.

## Discussion and Conclusions

The goal of this paper was two-fold. First to introduce FMP-combinations, and secondly to apply this to the development of Re-plex. Both topics are discussed below.

**Marita Sauerwein, Peter R. Mooij, Stephen J. Picken, Mark C.M. van Loosdrecht**





*FMP-combinations*

Approaching the development of bio-based materials for a circular economy as an FMP-combinations places the material in a broader context. Due to early material testing and prototyping with an initially sub-optimal material, all levels can inform each other for improvement. This helps to steer the which properties are required to meet the envisioned product lifetime and high value recovery. Therefore a better understanding is obtained of how the material can be used and should behave in a circular economy.

*Re-plex*

With the development of Re-plex, we prove the value recovery of a major organic waste stream. Due to the iterative process between feedstock, material and product level, we could extend the lifetime of an organic waste stream into a high value material for which interesting applications were found with market parties, i.e. façade panels for the building industry and 3D structures for nature restoration in aquatic settings. We could identify these applications early in the development process based on initial properties. The nature restoration structures exploit the biodegradability and strength of Re-plex, where the façade elements exploit the fire retardant properties of Re-plex. The field tests gave insight into the feasibility of the material for the envisioned product lifetime. For nature restoration this looks promising as microbiological activity and/or erosion took place on the samples, and despite breaking, the shapes are still intact after (more than) half a year. However, the brittleness and reproducibility remain a challenge for both cases and this requires further development. Hence returning to the feedstock level to further improve Kaumera by washing. This already indicates promising results for the façade panels on product lifetime as the washed samples are in significantly better condition than the non-washed samples after one month.

We would like to state that approaching Re-plex as an FMP-combination resulted in valuable applications that include sustainable resources and promises material optimisation towards appropriated lifespans.

## Acknowledgments

This work was supported by RVO TSE industrie. Re-plex was developed as part of the COMPRO project [TEBE119001] together with the following partners: NPSP bv., Chaincraft, TU Delft, BAM infra, BAM bouw en techniek and AMS institute. The 3D structures for nature restoration are developed with and for Waardenburg ecology. We would like to thank the following MSC MADE students for their meaningful contribution: Rakan Dajani, Maartje Molenaar, Jesse Bergman, Siddharth Agarwal, Femke de Kock, Amanda Schepers, and Roel Sipkema.

# Kicking the can down the Circular Economy Road – Basic needs in Standardization for Electronics- and ICT-products

**Schlegel, M.-C.**[(a)], **Giegerich, J.**[(b)]
a) Federal Institute for Materials Research and Testing (BAM), Berlin, Germany
b) Vorwerk Elektrowerke GmbH & Co. KG, Wuppertal, Germany

**Keywords**: Circular Economy; Electronics; ICT-products; Standardization; Legislation.

**Abstract**: As a consequence of the European Green Deal and the European Commission's Circular Economy Action Plan, the product landscape in the EU will undergo fundamental changes. The legal requirements for products are being expanded, not least through the Proposal for an Ecodesign Regulation for Sustainable Products published by the European Commission in 2022. Following the current developments, requirements for the circularity of products will be increased next to the already existing minimum requirements for products' energy efficiency. Following this development, the lead question has to be: Is the market, in particular small- and medium-sized enterprises, well prepared for this planned green transformation of our economy? The answer is: No, not yet.

What is needed are suitable standards for the implementation of these requirements to reduce additional burdens to an appropriate level and to support fair competition between all market actors concerned. The German Institute for Standardization, the German Commission for Electro-technical, Electronic & Information Technologies and the Association of German Engineers have conducted a review study with the aim of identifying fundamental needs for revising existing standards and for creating new standards - both of which are intended to support and accelerate the transformation of the current economy towards a Circular Economy. More than 700.000 normative documents were analyzed, and the results were discussed and consolidated with more than 1000 experts from manufacturers (organizations), consumer- and environmental organizations as well as from the public sector. As a result, more than 200 gaps in the standardization landscape were identified. In this study, we highlight and analyze the most important needs for standardization activities in the field of electrotechnical-, electronic- and ICT-products. In the discussion with the experts for electrotechnical-, electronic- and ICT products, it has been confirmed that a timely implementation of ambitious political decisions of a circular economy requires a normative basis to ensure its consistency. Furthermore, consensus between experts was that legislation in product regulation would be key and should not be extended to the area of waste legislation. As most important standardization activities accompanying product legislation, the following were identified: (i) creation of a set of indicators enabling a holistic assessment of product circularity, (ii) quality assurance of secondary raw materials and consumers awareness of the product circularity both enabled by appropriate analytics and (iii) clear regulation concerning product liability of repaired, refurbished or remanufactured products. One issue of relevance to all experts concerns the product safety, which must not, under any circumstances, decrease when changing product design to reach a higher degree of circularity. The mentioned and further standardization activities would be essential to kick the can down the circular economy road and are analyzed and summarized in this study.

## Introduction

The transformation from an almost linear to a circular economy was identified as fundamental to achieve appropriated resource savings, reduce productions impacts and to counter resource scarcity. During the past, one of the highest GHG-emission reduction was reached with regulation of the energy consumption during the use phase of products and recover of resources during products recycling. In 2015, the European Commission published the European Green Deal as a roadmap, which targets necessary measures to react on the current climate crisis (European Commission, 2015). In the wake of the Green Deal, the Circular Economy Action Plan clearly states that the circular economy should be implemented in existing legal frameworks European Commission, 2019, 2020). As consequence, the product landscape in the EU will undergo fundamental changes. The legal requirements for products are being expanded, not least through the Proposal for an Ecodesign Regulation for Sustainable Products, published by the European Commission last year (European Commission, 2022). Following this development, the following question remains: Is the market well prepared for this planned green transformation of our economy? To answer this question, the German Institute for Standardization (DIN), the German Commission for Electrotechnical, Electronic & Information Technologies (DKE/VDE) and the Association of German Engineers (VDI) have conducted a review study with the aim to identify fundamental needs in standardization, intended to support and accelerate the transformation of the current economy towards a more circular one - possibly ending up in a Circular Economy (DIN/DKE/VDI, 2023). In this study, we highlight and analyze the most important needs for standardization activities in the field of electronics and ICT-products.

## Method

National and international standards were reviewed to identify gaps or possible needs for revision of already existing standards and normative documents. In total, over 700.000 current references and thus the most comprehensive standards database in the world were analyzed automatically. 3,393 potential documents were manually checked for relevance and assigned to seven working groups dealing with digitalization, business models and management, electronics and ICT-products, batteries, packaging, polymers, textiles and buildings. After the qualitative check, a total of 2,066 documents were concluded as relevant. These were checked by the experts in the working groups and possible actions for standardization were determined.
In the following, the results of the most important needs of standardization measures for electronics and ICT-products were summarized and discussed. Beyond this summary and discussion, the results of the full study, also for the other product categories, are published by DIN/DKE/VDI (DIN/DKE/VDI, 2023).

## Results and Discussion

There are plenty of normative documents with relevance to the Circular Economy, however, in many cases they are addressing the circularity in a very broad manner and therefore do not have a systematic effect across all R-strategies defined by the United Nations Environment Programme (United Nations, 2023). The reason might be that a large proportion of the standards cover recycling, which has been treated as a priority topic in the Circular Economy of electronics and ICT-products in the past. Higher level strategies such as Rethink, Refuse and Repurpose were hardly addressed and have little or no representation in the set of already existing standards.

From the total list of 2,066 Circular Economy-relevant standards, 328 documents could be assigned to the area of electronics and ICT-products. This indicates that a significant number of relevant standards have already been produced, especially for the strategies Rethink, Reduce and Recycle. The strategies Reuse, Repair, Refurbish and Remanufacture are the subject of individual standards. Refuse and Repurpose are hardly considered. The same picture can also be seen when looking at the individual sectors of household appliances, large-scale products and installations and ICT-products.

The large number of standards for Reduce (by design) and Recycle can be explained by the fact that electronics and ICT-products have been the subject of a set of European legislation (European Union, 2009, 2012, 2017; European Commission, 2019a-i, 2013a-c) for a considerable time. Harmonized standards are the basis for legal requirements. In addition, the standardization mandate M/543 (European Commission, 2015) was issued in 2015 in the context of the then planned further development of the Ecodesign Directive. In this mandate, the European standardization organizations CEN, CENELEC and ETSI were requested to develop generic standards for the assessment of different material efficiency aspects (durability, reparability, reusability, remanufacturability, recyclability, recycled content) of energy-related products. This has resulted in the EN 4555x series of standards, which provides the basis for the development of product-specific standards on the R-strategies.

The review study by DIN/DKE/VDI and the related discussion with the experts in the field of electronics and ICT-products concluded that while increasing the circularity of products, there are almost no restrictions due to the type of product. However, all products have two things in common: [i] it is adequate to look at the entire lifecycle and [ii] product safety and other safety aspects must not be compromised. The experts for electronics and ICT-products, agreed that a normative basis is needed to enable a timely implementation of ambitious circular economy product requirements, not at least to ensure technical consistency. Furthermore, consensus was reached that product legislation should be preferred instead of extending to the field of waste legislation.

As most important standardization activities accompanying the product legislation mentioned in the previous paragraph, the following were prioritized by the expert for electronics and ICT-products:

*Creation of a set of indicators enabling a holistic assessment of product circularity*

The development of standardized calculation methods for indicators of the individual R-strategies would enable the consideration of the overall circularity of a product. The indicators would thus provide a consideration of the Circular Economy in internal control systems and would finally open possibilities for the (re)orientation of business models and strategies. Methods for the comparability of R-strategies and possibilities of combined considerations, for example through a conversion into GHG-gas savings, are seen as essential. For the latter, a definition of system boundaries at European and, if possible, international level is required. A national consideration of the circularity of products, especially in the context of international value chains, is not seen as being purposeful.
Finally, the application of R-strategies must not reduce significant product characteristics such as product safety, and producers' obligations and liability should also be considered. Correspondingly, detailed product information enables a detailed description of the products and a finely granulated differentiation of the products on the market based on this. Products could be purchased, used or installed in a more targeted and demand-oriented manner. This includes a larger number of reused, repaired, refurbished or remanufactured products and thus increases the overall circularity of electronics and ICT-products.

*Quality assurance of secondary raw materials and consumers awareness of the product circularity both enabled by appropriate analytics*

An increase in the use of recycled materials in new products can be reached through defined material properties. Material standards based on the type of material, under consideration of the required technical properties of the intended application, are key. These can be supplemented by information on the presence of declarable substances according to harmonized or international standards. This would further increase the acceptance of secondary raw materials in general and thus make a significant contribution to the transition of the current- to a circular economy. These considerations clearly go far beyond polymers, which are often used as example for discussing recycling. The range of non-ferrous metals, including standard alloys, is very wide in terms of a possible obligation to declare. This means that standard materials from one manufacturer may not be subject to declaration, but from another manufacturer they may be subject to the requirements of the REACH Regulation (European Union, 2006). Standard mate-rials and of suitable reference materials can solve this issue and increase the use of recycled materials in new products. The reference materials would enable to surveille legal requirements. In addition, making the information concerning the circularity of a product, such as the recycled content, visible to the consumer, might push sustainable decision-making processes at the point of sale. An information standard for consumers can support assessing the circularity of products. For this purpose, suitable indicators (as described in the previous section) should be developed that enable an assessment of the circularity.

*Clear differentiation between repaired, refurbished or remanufactured products*

The refurbish strategy deals with the extension of product durability by renewing and/or re-pairing individual but essential components. Refurbishing must be clearly differentiated from remanufacturing: In the case of refurbishing, the product identity is retained and it is not placed on the market again. In the case of remanufacturing, the product identity is lost; the remanufactured product is a new product that must be placed on the market again. Accordingly, a remanufactured product must meet the legal product requirements at the time of being placed on the market. For standardization bodies, this means that the possibility of product remanufacturing must be considered and clearly distinguished from refurbishing. This concerns both product safety and product design requirements. Currently, there is no normative basis for rebranding of products such as the removal of the original manufacturer's name plate and the addition of the name of the remanufacturer. While this process is common for industrial machinery, the situation is unclear for consumer products. The possibility of renaming can be limited by various factors, such as product design and copyright protection. This makes it difficult to differentiate between original manufacturers and preprocessors, e.g. in regards to products liability. Therefore, the need for a guideline was clearly identified, which provides guidance on the circumstances under which a renaming must take place.

## Conclusions

It is fundamental that R-strategies are already considered in the design phase of products. This requires guidelines with a global approach, such as those developed by the Circular Plastics Alliance for recycling (European Commission, 2021). It must be considered that not all R-strategies can be implemented equally for a product, but a corresponding priority needs to be set. For example, for some easy-to-dismantle products the design priority is on maintenance and repairability, whereas for other more robust products the design priority is on durability. Therefore, an appropriate and easy-to-apply approach for the purpose of the life cycle analysis should be found, which allows the assessment and evaluation of the individual strategies for a specific product or product group. This might result in an optimized balance between the R-strategies.

# Chaos and synergies: Review of the first three years at the "Haus der Materialisierung"

**Johannes Scholz[a], Isabel Ordonez[b], Paula Miels [a], Vera Susanne Rotter [a]**
a) Department of Environmental Technology, Chair of Circular Economy and Recycling Technology, Technische Universität Berlin, Strasse des 17. Juni 135, 10623 Berlin, Germany
b) ELISAVA, Barcelona School of Design and Engineering, La Rambla, 30, 32, 08002, Barcelona, Spain

**Keywords**: Circular Economy; Reuse networks; Waste prevention; Urban resource centre.

**Abstract**: The Haus der Materialisierung (HdM) is the physical and organisational centre of a network of initiatives focused on material and product re-use, repair and remanufacturing. Located in the centre of Berlin, 26 initiatives temporarily use a 2000 m² building, while an ambitious renovation process of the entire complex is underway. The HdM was established with the shared vision and mission of promoting sustainable practices such as waste prevention, collaborative consumption, repair and reuse. It currently includes secondary materials marketplaces, open workshops, entrepreneurship, and capacity building activities. This article reviews HdM leading group's meeting protocols, to provide an insight of the processes lived during the first 3 years of establishment in this space. The protocols were read, tagged and analysed to identify the synergies and difficulties that have appeared during this time, providing detailed information about how it is to manage a collective resource centre run by a network of independent reuse initiatives without a legal entity. Like in any collective space, internal communication is key to a well-functioning organisation, and it is common that differences of opinion, or repetitive neglect from some network members with common chores generate internal irritation. However, the synergies and collaborations seem to overweigh the conflicts and difficulties encountered.

## Introduction

The lifetime of a product is oftentimes limited to a single use phase until it reaches its End of Life (EoL), where it is discarded as waste. Preventing a product from becoming waste by applying R-Strategies like repairing, repurposing, re-using or remanufacturing is a crucial activity for extending a product's lifetime (United Nations Environment Programme [UNEP], 2019). This is one of the main ideas promoted by the Circular Economy (CE). Products and materials are frequently disposed of as waste in urban areas due to CE barriers such as lack of knowledge or infrastructure (Kirchherr et al., 2018).

Many recent projects have promoted CE practices in cities across Europe. The Reflow project used FabLabs and grassroot organisations as catalyzers for a CE transition, developing a set of indicators to account for the social, environmental and economic impact of such activities (REFLOW, 2021). The Pop-Machina project aimed to promote CE activities by supporting the maker movement to perform R-Strategies through collaborative production (Pop-Machina project, 2023). Both projects connect CE to active citizen engagement in distributed production facilities such as FabLabs, but do not focus specifically on what materials are used in such activities. The Resourceful Cities project focused on developing next generation Urban Resource Centres (URC), i.e. "physical centres that help facilitate sustainable consumption, waste prevention, re-use, repair and recycling in urban areas (including re-use centres and recycling stations)" (Partnership on Circular Economy, 2019). These centres can be multifunctional, and tend to work with materials already available in cities.

One such urban resource centre is the "Haus der Materialisierung" (HdM) (HdM, 2023). The HdM is the physical and organisational centre of a network of initiatives focused on reduction, re-use, repair and remanufacturing. Located in the centre of Berlin, 26 initiatives have been given the opportunity to use a 2000 m² building for a period of four years, as part of the pioneer use during the renovation of the Haus der Statistik (HdS) (HdS, 2023). The HdM was established with the shared vision of promoting sustainable practices such as waste prevention, collaborative consumption, repair and reuse. Based on the concept of Centers for

Urban Remanufacturing (CURE) (Ordóñez et al., 2019), the HdM now includes secondary materials marketplaces, open workshops, entrepreneurship, and capacity building. Organisations gained access to the space in mid 2019, and in May 2020 the HdM opened to the public, offering a variety of services.

The HdM is a unique case study that has opened a public space for reuse, repairing and remanufacturing. It is a bottom-up organisation, who’s main driver is to promote repurposing activities among the general public. It differs from most other URC in that it is not managed by a local authority or a single institution. It is a network of initiatives that, by sharing a space and pooling their efforts, hope to draw more attention to sustainable resource consumption.

In parallel, the research project "Practical implementation of the circular economy in an urban context: environmental communication in the House of Materialization", started in November 2019. In this project, researchers from the Chair Circular Economy and Recycling Technology at TU Berlin were engaged for three years in documenting the establishment of the HdM and participating in its activities as cooperation partners.

This article aims to give an overview of the founding process of the HdM with a focus on how independent organisations become a network. To do so, the article covers the following points: 1) Organisation and operation of HdM activities 2) description of the collaborations and synergies v/s the difficulties and conflicts among HdM actors. The basis for these findings are the protocols of the bi-weekly HdM board meetings, covering the first three years of activities. The results of this study can be used as documentation so that similar projects can benefit from the experience of the HdM start-up process.

## Methods

The HdM has been operating since mid 2019, gathering independent organisations in one shared space. To use the space and collaborate, these organisations meet biweekly in what they call a “core group meeting” where hopefully a representative of each organisation participates. These meetings result in protocols that are shared with all HdM members and serve to document the discussions and decisions taken by the group. This article reviews the core group meeting protocols for the past 3 years (i.e. since Nov.2019-Nov-2022, covering 82 meetings), to describe how the organisation and operation of the HdM has changed during this period, to identify milestones, and to evaluate if the collective space has brought more benefits or problems to its participating members.

The meeting protocols were analysed using the open-source qualitative research tool Taguette. A total of 18 tags were used, grouped into three main groups:

- **Value Assessment:** C*ollaboration, Conflict, Difficulty, Big Decision and Milestone*.
- **Descriptive - Strategic:** *Mission and Vision, Organisational Structure, Joint communication to exterior, Economy, Educational offer, Pioneer joins* and *Pioneer leaves.*
- **Descriptive - Regular:** *Attendance list, Shared Infrastructure, Ko-Market, Subbotnik, Other Events* and *Tour.*
- 

Tag groups were intended to clearly state what tags required a subjective value assessment from the reviewers, and which ones were merely descriptive labels for the content. Of the descriptive labels some are considered to be more strategic to the HdM operations, while the regular ones are mostly coordination of regular activities. Reviewers could use several tags to describe one piece of referenced text if so desired, providing more detail to the content.

Once all protocols were tagged, the selected extracts were reviewed and organised into affinity diagrams using a joint Miro board. These affinity diagrams are the base of how the content is described in the following sections. Repeated topics were grouped in order to know how many individual topics were addressed under each tag used. Additionally, a quantitative overview of the use of each tag, and their temporal distribution was done to try to identify possible seasonal patterns in the data. Given the article’s length limitation, this paper will only provide an overview of the descriptive tags, and review more in detail the value assessment tags, still providing input to what other tags the content was related to.

## Results

In total 891 tags were assigned to the different topics. Figure 1 provides an overview about the number of tags in the three defined groups over the analysed period. Since the value assessment tags are of special interest for this article, the containing tags are displayed on their own. Additionally, important milestones for the HdM establishment are shown.

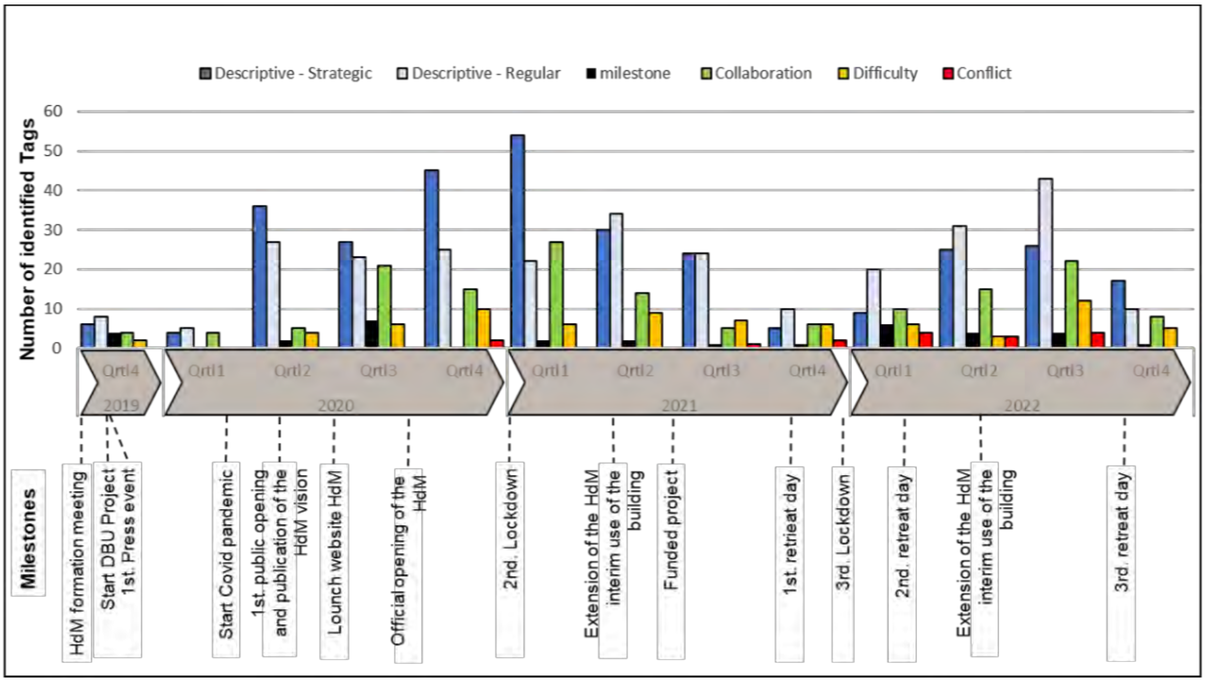

**Figure 1. Temporal distribution of tags in the period 4th quarter 2019 - 4th quarter 2022 with project milestones.**

### *1.1. Organisational Structure & Operation*

The HdM operates by the self-organisation of its members, based on democratic principles and votes for decisions. ZKB (Zusammenkunft Berlin) as the coordinator and landlord of the various initiatives throughout the HdS supported at the beginning the formation process of the HdM with coordination and legal and administrative issues and is the link to the state of Berlin, the owner of the HdM. The "core group meeting" is the central body for decision-making. A total of 572 regular and strategic

**Figure 2. Affinity diagram showing the topics from the organisational structure tag, ordered from top left to bottom right according to the number of issues in each group.**

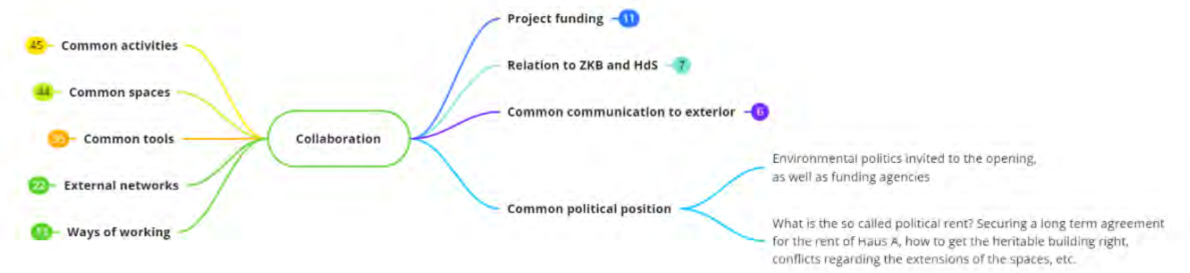

**Figure 3. Affinity diagram showing the topics from the Collaboration tag, ordered from top left to bottom right according to the number of issues in each group.**

descriptive tags were identified in the HdM's operation. 102 tags are directly focused on the organisational structure of the HdM and displayed in the affinity diagram in figure 2. Most discussed are the shared infrastructure and administrative questions. The administration heavily depends on the engagement of the members since this is unpaid work. Defined topics are frequently prepared in temporary or permanent working groups, e.g. resources, events or communication.

The HdM does not exist as a legal entity and is based on collaboration in the network without defined financial responsibilities. This leads to economic discussions about how to cover common expenses, but also about how to get paid for common services provided to external clients or how to apply for funding.

Since the HdM has the short term use of space in a public construction site, how it is used is an important topic (20 tags). Most initiatives are renting their own room or are sharing a location with other initiatives. The use of common areas or hallways is often discussed. This also includes the security and cleanliness of the building and the ownership of goods and tools.

Initially the temporal usephase of the HdM was planned until December 2021. Since then, the allowance of using the space has been extended several times. This unsure use of space situation and the future of the HdM are often discussed (11 tags).

### *Collaboration v/s Conflicts and Difficulties*

These tags were defined by the researching team as following:

- **Collaboration**: Two or more pioneers work together on something other than regular open hours/events.
- **Conflict**: Text describes a conflict among two or more of the pioneers.
- **Difficulty**: Some sort of problem is described that has made it difficult to do something, things were harder than expected.

The tag "Collaboration" was used in total 156 times, referring to a total of 136 different issues. It was most used along with other tags, with the most common joint tags being Common communication to exterior (48 times), Organisational structure (38), Other events and Shared infrastructure (both 24 times), Difficulty (16 times), and Economy (15 times). These tags were organised in an affinity diagram, with a total of 9 distinct groups (Figure 3). The most frequent topic for collaboration was the joint development of common activities.

Even though some of the tags refer to regular activities (i.e. regular open hours, subbotniks or cooperative markets), the text highlights a change in how it is done. Or the establishment of a new regular activity (e.g. a new workshop starts to operate, a volunteer hour system is established). New activities are proposed by some of the actors during the meetings, usually expecting the rest of the group to join or support the activity at the HdM somehow (e.g. organising a retreat day or the official opening event). General topics for the use of the space are frequently discussed (e.g. electricity connection, access keys and regular maintenance tasks), as well as how to organise and use the rooms. Common spaces such as the warm room (heated space during winter months), the showroom, reception and kitchen receive most attention. The tools shared among HdM actors are a mix of digital (i.e. shared documents, contact lists, webpage) and physical tools (i.e. cashbox, giftshop, donated material and tool library).

The tags grouped under "external networks" and "common communication to exterior" (Figure 3) are really where it can be seen that the HdM actors start to build a sense of identity as a group. Either by presenting the HdM at external conferences or events (e.g. at museums, Biennale), or describing the HdM in the broader reuse network or reuse mapping as a single entity. These references still have some tension regarding who is suited to be an official spokesperson for the group, or how the HdM gets represented in different media, since it might not be considered accurate or fair by some actors. The remaining "collaboration" tag groups (i.e. Ways of working, project funding, common political position and relation to ZKB and HdS), refer mainly to how the HdM actors have managed to work together and relate to the broader renovation of the HdS. During this period, at least 5 joint applications have been developed by HdM actors, however, none of these applications are presented with all of the HdM initiatives.

The tag "Conflict" was used 16 times, and was tagged with Difficulty (6 times), Collaboration (4), Organisational structure (twice), Other events and Economy (once with each). It might seem a contradiction to have both the tag conflict and collaboration on an item, but these tags refer specifically to the lack of collaboration among partners, where some members of the HdM express a lack of unity or sense of collective identity. Other reasons for conflict were mainly based on lack of clarity or miscommunication among the actors. A noticeable example refers to the lack of clarity among some actors regarding what will happen with the space once the renovation of the site reaches the building they currently occupy. It was stated from the beginning that they may be able to move to another space on the premises, but the exact terms for that new temporary use are still being discussed in the wider meetings with all pioneer users (not only the HdM initiatives) and the administrators of the ongoing renovation project. This has been a source of irritations and insecurity for those HdM initiatives that feel left out of the process. This topic is crucial for the development of the HdM, and as such it is the main issue addressed during the retreat days that HdM initiatives organise. On other occasions the conflicts have appeared due to a difference in opinion among members, regarding for example the use of FPP2 masks inside the HdM while working, or putting a hemp plant for cooking on the premises. The last source of conflict identified was the lack of tidiness in common areas, a recurrent problem in shared space.

The tag "Difficulty" was used 76 times and tagged jointly most commonly with Shared infrastructure (17 times), Collaboration (16), and Organisational structure (16). Issues most often discussed refer to neglect in the use of the premises (e.g. dirty toilets or kitchen, accumulation of waste, doors left open when there was no one). Other difficulties described are in reaching a consensus on how the HdM is to be portrayed in public (e.g. on the shared webpage, in a TV reportage), how decisions are made and informed among the group, or how regular activities get organised. Uneven distribution of tasks is commonly commented, contributing to the feeling that some actors have more work (and more responsibility) than others.

The collaboration between former independent actors at one central location in the city has not been easy. But looking at what is discussed during the meetings, it seems that more time and energy is spent talking about collaborations (with 156 tags) than on conflict and difficulties (jointly 92 tags). There may be an implicit bias in using the tag "collaboration" as groups tend to talk about the things they collaborate on. Thus, it can be expected that this would be the most recurring intent in the meeting minutes. However, reviewing the collaboration tags, provides insight into what has been collaborated on, and thus it was deemed useful despite its implicit bias.

## Discussion
The analysis of the founding and operating process of HdM offers insights into the extent to which a CE network's activities are generated by a shared location and a shared mission and vision. Providing affordable space in a centrally located area can have a catalytic effect on connecting independent local CE actors into a shared network of actors. This network creates a variety of collaborations that are beneficial to both the initiatives and their clients, since improved services get offered regularly.

A reuse network based on the self-organised collaboration of independent initiatives is a difficult administrative task, riddled with conflicts and difficulties. The large number of individual actors with different goals and without a legally defined project leadership can

sometimes lead to chaos and frustration. However, the retreat days in particular, show that the shared vision and mission of the actors are enough motivation to continue the project. As a result of the collaboration established so far, and as part of the professionalisation of the HdM, the group is now in the process of becoming a legal umbrella organisation.
Future research around the HdM should include a review of how effective waste prevention is by applying the R-strategies and what measurable impact these practices have on people and product lifetimes.

Like in any collective space, internal communication is key to a well functioning organisation, and it is common that differences of opinion, or repetitive neglect from some members with common chores generate internal irritation. However the synergies and collaborations overweigh the conflicts and difficulties encountered, to the point that this groups of independent initiatives, became a collaborative network that is on its way to become an established organization.

## Acknowledgments

The authors wish to acknowledge the project partners from the HdM. The project "Reallabor Zirkuläres Wirtschaften im urbanen Raum: Kompetenzaufbau und Umweltkommunikation im "Haus der Materialisierung" in Berlin" is technically and financially supported by the Deutsche Bundesstiftung Umwelt.

# How can games aid co-design of user-centered circular offerings?

**Anneli Selvefors[(a)], Sara Renström[(b)], Hanna Nordenö[(b)], Erik Einebrant[(b)], Sara Fallahi[(b)], Katherine A. Whalen[(a)], Matilda Leivas[(a)]**
a) RISE Research Institutes of Sweden, Sustainable Business, Gothenburg, Sweden
b) RISE Research Institutes of Sweden, Technologies for Interaction, Gothenburg, Sweden

**Keywords**: Circular business model; Circular design; Serious game; Co-design; User-centered design.

**Abstract**: Widespread adoption of circular offerings, including those based on products with prolonged lifetimes, depend on offers which are attractive to users. To develop such offers, user needs must be considered in depth during the development process. Co-design is a promising approach to develop user-centered solutions but is yet underexplored when it comes to design of circular offerings. To facilitate co-design of circular offerings, games present one opportunity but have previously primarily been used to support understanding, creation, and learning in relation to circular economy. This paper explores how games can support co-design of user-centred circular offerings by presenting insights from an analysis of existing circularity-related games and summarizing insights from literature. Eight circularity-related games were played to identify benefits and drawbacks. Relevant literature was also reviewed to synthesise recommendations for a game aimed at supporting co-design of user-centred circular offerings. The results show none of the existing circularity-related games include a deep understanding of users' needs and only a few go beyond mere learning and actually contribute to developing companies' offerings. Identified recommendations suggest games will have higher potential to support co-design of user-centred circular offerings if they, for example, enable co-design with users and co-creation with multiple stakeholders in the business ecosystem, provide game elements that represent circular challenges and opportunities in a realistic and dynamic way, and create bridges from the game to the real world. Future game development should hence take such recommendations into account, while ensuring the developed games do not become too complicated to play.

## Introduction

Despite the potential of circular business models (CBMs), widespread adoption has not yet taken off. One reason is the difficulty of creating attractive circular offerings that address users' needs in a satisfactory way (Rexfelt & Selvefors, 2021). Previous research therefore emphasizes the importance of creating value propositions that both meet user needs and align with circular economy goals such as prolonging product lifetimes (Tunn et al., 2019).

Although processes and methods for circular innovation can help companies to develop different CBMs, services, and products, opportunities to develop user-centered circular offerings are still often overlooked. Some methods stress that a user perspective can be valuable, e.g., to assess the market potential of CBMs, but they do not to any further extent aid companies in gaining and transforming user insight into attractive circular value propositions (Rexfelt & Selvefors, 2021), nor do they facilitate co-design and experimentation with users (van Dam et al., 2021).

Design approaches such as user-centered design (Abras et al., 2004) and co-design (Sanders & Stappers, 2014) have shown potential for helping companies to gain insight into people's everyday life and identify opportunities to better meet user needs, but they are still underutilized when it comes to development of circular offerings (Lofthouse & Prendeville, 2018). Another promising but underexplored approach is to use games as tools for companies to co-design circular value propositions together with users. Previous research suggests game-based approaches can aid sustainable innovation (Whalen & Kijne, 2019) by, for instance, encouraging critical thinking and mimicking complex systems (Whalen, 2017; Whalen et al., 2018).

The aim of this paper is to provide insight into how games can aid co-design of circular offerings to increase their attractiveness and potential for adoption.

## Method

Two main activities were carried out to further the understanding of how games can aid co-design of circular offerings.

First, existing circularity-related games were analysed to explore their potential to aid development of user-centered circular offerings. An initial list of 24 games was compiled and eight games were selected for more in-depth testing and analysis. This selection was based on four criteria: the game should address CBMs and/or circular design; the target group should be professionals or students that work with CBMs or circular design; the game should be relevant to play for different companies; the game must be available and offered in English. The shortlisted games (see Table 1) were played according to game instructions by 3-10 people including the authors (but excluding creators of the games) and at times additional players. After each game session, the players discussed benefits and drawbacks of the games in general and particularly in relation to co-design of user-centered circular offerings. Based on the discussions, a thematic cross-game analysis was conducted with an inductive approach.

Second, a review of literature was performed to explore recommendations and insights related to success factors for CBM development, co-designing circular offers, and games supporting the development of circular offers. Multiple database searches were conducted in Scopus combining variations of the following keywords: circular economy, circular business model, circular design, circular ecosystem, circular innovation, value proposition design, game, tool, gamification, collaboration, co-design, co-creation, participatory design, circular consumption, customers, users, and consumers. The search yielded 98 papers after

| GAME | PURPOSE | FOCUS | FORMAT | TARGET GROUP | DESCRIPTION | ACCESS |
|---|---|---|---|---|---|---|
| GAME A: **The Blue Connection** | To increase knowledge and awareness | Business models; Design of products and services | Digital interface (app or website) | Professionals | *The game is played in teams where players take on different roles in a manufacturing company. The aim is to transform a fictive company's linear value chain to a circular one. Players must make strategic decisions in regards to sales, purchasing, supply chain, and finance to gear the business towards long-term goals. Players will learn the impact different circular strategies have on the business from a financial and circular perspective.* | https://inchainge.com/business-games/tbc/ |
| GAME B: **Circula Circular Economy and Entrepreneurship Game** | To increase knowledge and awareness | Business models | Board game (game board, cards, etc) | Students; Professionals | *The game is played in teams to come up with ideas for new companies that address a real need, use natural resources in a sustainable way, and can become profitable businesses. Players must define their circular value proposition and decide on company activities, target group, and roles. Players will learn to work in teams and utilise skills, strengths, and resources to develop ideas for new businesses.* | https://circula.fi/en/ |
| GAME C: **ecoCEO** | To increase knowledge and awareness | Business models; Material flows | Board game (game board, cards, etc) | Students | *The game is played individually and each player takes on the role of a CEO tasked with making their company both profitable and resource-responsible. Each player must make smart investments to safeguard resources, diversify the product portfolio, improve production processes, and respond to global challenges to find new business models that maximise profit. Players will learn about sustainable entrepreneurship, resource scarcity, waste management, and business strategies.* | https://ecoceo.vito.be/en |
| GAME D: **Eco Designer** | To increase knowledge and awareness | Design of products and services | Combination of board game, digital interface, and templates | Students; Professionals | *The game is played in teams representing companies that are tasked with reducing the environmental load for their products. Players must make decisions that influence impacts throughout the product's lifecycle, including investing in research and development, new materials, and other actions. Players will learn about how different aspects influence a product's environmental load and eco-design strategies.* | https://gametools.dk/portfolios/eco-designer/ |
| GAME E: **In the Loop** | To increase knowledge and awareness | Material flows | Board game (game board, cards, etc) | Students; Professionals | *The game is played individually and each player represents a manufacturing company that relies on different materials to produce products. Each player must collect materials and produce products while considering which circular strategies might be relevant to invest in to reduce risks related to material criticality. Players will learn about critical materials, circular strategies and global resource supply chains.* | https://intheloop game.com/ |
| GAME F: **KATCH Up!** | To increase knowledge and awareness; To aid development of circular offerings | Business models; Design of products and services | Combination of board game and templates | Students; Professionals | *The game is played in teams that are tasked with generating ideas based on a fictive or real business challenge. Players should try to tackle the challenge using circular design and business strategies and generate value opportunities. Players will learn about circular strategies, circular business models, and the role other stakeholders play for the implementation of circular design strategies.* | https://www.katche.eu/knowledge-platform/ |
| GAME G: **Models of Impact** | To increase knowledge and awareness; To aid development of circular offerings | Business models | Templates (canvases, forms etc) | Professionals | *The game can be played individually or in teams to ideate new, sustainable business models. Players go through a series of activities that simulate the process of ideating and launching a social enterprise. Players learn about different types of revenue models and impact models and gain insights into how these can be combined into innovative business models.* | http://www.modelsof impact.co/ |
| GAME H: **Risk&Race** | To increase knowledge and awareness | Business models | Board game (game board, cards, etc) | Students; Professionals | *The game is played in teams that represent manufacturing companies who must decide on which circular strategies to implement. Players have opportunities to invest in infrastructure, technological innovation, human resources, and business strategies to strengthen their company and remain profitable. Players learn about circular opportunities and financial implications of different business models and investments.* | https://riskandrace.vito.be/en |

**Table 1. The analysed circularity-related games.**

excluding non-relevant titles. After reviewing abstracts and excluding duplicates, 46 papers were read in full to extract recommendations and insights about success factors. The data was thematically analysed and synthesised into three sets of recommendations for co-design of user-centered circular offerings.

## Analysed circularity-related games

As described in Table 1, the analysed games have varying purposes, focuses, and formats. Most of the games are designed to aid companies' learning processes through fictive cases rather than support work practices involving dialogues with stakeholders and development of new, implementable circular offerings. Only two (games F and G) enable companies to address their current challenges and explore circular opportunities. However, these can be considered more tools than games since they are designed to facilitate structured design processes. Although intended to facilitate design processes, they do not include or represent users or customers to any large extent. None of the tested games provide support for exploring opportunities, testing value propositions, or co-designing circular offers with users.

By testing and analysing the games, additional benefits and drawbacks were identified regarding six main topics:

### *Addressed circular opportunities*

Most of the games (A, C, F, G, and H) focus on introducing a range of pre-defined circular opportunities (such as shifting to rental or second hand offers, remanufacturing products, and recycling materials) that players should pursue to gain victory points or create a winning business pitch. The games do not, to a large extent, include critical evaluation of the opportunities. They are presumed to be desirable regardless of case, company preconditions, and user needs.

Moreover, some games (B and D) focus on opportunities to utilise or optimise current linear waste streams, rather than opportunities to address systemic challenges and possibilities to pursue circular opportunities with more transformative potential.

None of the games solely focus on longevity and extended product lifetimes. In fact, several of the games (C, E, and H) implicitly encourage increased resource flows since players gain benefits from large and speedy flows.

### *Stakeholder representation*

All analysed games focus on circular challenges and opportunities from a company perspective. A few (A and B) include representation of different departments or roles within a company, which highlights different perspectives must be considered. Sometimes compromises must be made when, for instance, making investments, deciding on circular strategies, and taking action to reduce the environmental impact. Specific customer or user wants and needs are not explicitly represented in the games. A few (F and H) include generic target group descriptions, or information on their willingness-to-pay, but exploring user needs, potential acceptance, and experience of circular offers are not part of the games.

### *Player interaction*

All analysed games build on competition rather than cooperation between players or teams of players. Some games (D and E) specifically enforce competition by enabling players to contribute negatively to other player's progress through investments that make desired actions more costly or impossible for the other players. The games that have some collaborative elements (C and H) enable teams to build on each other's strengths, learn from each other, or team-up when mutual benefits are to gain.

### *Game usability*

How easy or difficult it was to play the games depended on each game's components (the physical or virtual materials, such as boards, cards, and forms) and mechanics (the processes driving actions, such as elements of chance, feedback, and competition). The games that were considered especially cumbersome to play (A and D) are characterised by unclear logics regarding rules and limitations, unclear links between actions and game points, lack of supportive visualisations or process representations, and game components with low usability. Some of the games were easier to play due to either simplified game setups (B, C, G) or clear instructions as well as game components and mechanics that provide a supportive structure to help players understand how to play the game (C and H).

### *Game experience*
The games that were considered especially engaging and fun were the ones (E, G, and H) that are satisfactorily challenging, enable players to pursue different circular opportunities, provide easy-to-use and visually appealing game components, enable meaningful interaction between players, enable concurrent playing, and represent reality in a relevant way through game components and game mechanics.

### *Expected outcomes*
Given that all analysed games aim to increase knowledge and awareness, players can expect to gain an increased understanding of circular flows, circular strategies, and circular business models. However, specific learnings are dependent on how these circular concepts are represented in the games. Games built on very simplified descriptions of circular concepts (B, C, D, F, and G) will not yield any significant learnings for players that already have a basic understanding of circular concepts. Furthermore, games with either simplified game mechanics (B, C, F, and G) or game mechanics that do not represent real world circular pre-conditions in a sufficient way (B and D) risk portraying circular opportunities as, for instance, easy endeavours or desirable options regardless of real-world conditions. To be able to transfer learnings to everyday work practices, players need to feel that the game models reality and the circular opportunities in a good way.

## Recommendations for future games
Twenty-six recommendations were formulated for future games aimed at aiding co-design of user-centered circular offerings: ten recommendations for development of circular offerings; eight for co-design with users, partners, and both; and eight for games for development of circular offerings.

Table 2 lists the ten recommendations regarding development of circular offerings. One recommendation especially relevant to highlight is to safeguard the sustainability agenda. Previous research shows that even though sustainability impact is the aim of the development of circular offerings, this perspective can get lost during the process in favour of economic concerns or fulfilment of user needs (e.g., N. M. P. Bocken et al., 2018; Sumter et al., 2020). Measures to safeguard the sustainability agenda must therefore be considered when developing circular offerings.
Another important recommendation is to experiment with circular offerings at different stages of development, as this is an effective way of learning what does and does not work (e.g., N. M. P. Bocken et al., 2018; Brown, Von Daniels, et al., 2021). Experiments close to the real-world conditions are preferable, as well as experiments that include users (Antikainen & Bocken, 2019).

Finally, co-design with users and partners is a recommendation for development of circular offerings (Brown, Baldassarre, et al., 2021; Fernandes et al., 2020; van Dam et al., 2021). Table 3 presents recommendations for how to co-design circular offerings with users, partners, and both.

| | |
|---|---|
| Safeguard the sustainability agenda | (Manninen et al., 2018) |
| Base development on user needs | (Hankammer et al., 2019) |
| Consider the full spectrum of circular opportunities | (Rosa et al., 2019) |
| Align design and business logics | (Sumter et al., 2020) |
| Engage different disciplines | (N. M. P. Bocken et al., 2019) |
| Experiment with iterations of circular offerings | (N. M. P. Bocken et al., 2018) |
| Create an impactful partner ecosystem | (Trevisan et al., 2022) |
| Co-design circular offerings with users | (van Dam et al., 2021) |
| Co-create circular offerings with partners | (Brown, Baldassarre, et al., 2021) |
| Co-create circular offerings with both users and partners | (Fernandes et al., 2020) |

**Table 2. Recommendations for development of circular offerings and examples of reviewed literature used to synthesise the recommendations.**

There are few recommendations for co-designing of circular offerings with users. Those that exist include using insight about the everyday as a basis for co-design since the impact of circular offerings depend on how they are used in real life (Clark et al., 2020). Another recommendation is to use co-design with users for ideation and not for validation, as it can be difficult to include enough users to validate findings (van Dam et al., 2021).

| | |
|---|---|
| Motivate users to engage in co-design | (Gimenez-Fernandez et al., 2021) |
| Use insights about the everyday as basis for co-design | (Clark et al., 2020) |
| Use co-design for ideation (not validation) | (van Dam et al., 2021) |
| Expand the co-creation team over time | (N. M. P. Bocken et al., 2018) |
| Moderate the co-creation process | (Boldrini & Antheaume, 2021) |
| Support active collaboration among partners | (Fernandes et al., 2020) |
| Create common visions and goals for all partners | (Pedersen & Clausen, 2019) |
| Manage knowledge sharing | (Brown, Von Daniels, et al., 2021) |

**Table 3. Recommendations for co-designing circular offerings with partners, users or both and examples of reviewed literature used to synthesise the recommendations.**

| | |
|---|---|
| Make expected game outcomes relevant | (Milutinovic et al., 2018) |
| Create a bridge between the game world and the real world | (Milutinovic et al., 2018) |
| Make focal game elements realistic (and simplify the rest) | (Jääskä et al., 2021) |
| Make game conditions dynamic and future-proof | (Dufva et al., 2016) |
| Enable players to empathise with each other | (Dufva et al., 2016) |
| Spur creativity and flow | (Zhang et al., 2021) |
| Create space for reflections and shifting of perspectives | (Whalen et al., 2018) |

**Table 4. Recommendations for development of games for circular offerings and examples of reviewed literature used to synthesise the recommendations.**

When it comes to how to co-create with partners (private or public companies, non-profit organisations, research institutes, etc.) more research has been conducted. One important recommendation is to create common visions and goals for all partners (e.g., Boldrini & Antheaume, 2021; Konietzko et al., 2020; Pedersen & Clausen, 2019). Another set of recommendations concern how to lead the co-creation. For example, the process should preferably be moderated (Boldrini & Antheaume, 2021) and knowledge sharing between stakeholders must be managed (e.g., Cantele et al., 2020).

Recommendations related to games for developing circular offerings are presented in Table 4. An important recommendation to highlight, especially as most of the games analysed in this paper aim to increase knowledge and awareness, is to also create outcomes that are relevant for the players day-to-day work practices. Another important recommendation is to make the focal elements of the games realistic enough while not making the game too complicated (e.g., Jääskä et al., 2021). Finally, for a game that would include both users and providers, creating empathy for each other is crucial (e.g., Dufva et al., 2016).

## Concluding remarks

Our research contributes to building knowledge on how games can aid co-design of user-centered circular offerings in two ways. First, we shed light on the benefits and limitations of existing circularity-related games. Second, we identify gaps in the current game landscape and suggest recommendations for new games by synthesising insights from literature.

To conclude, there appears to be a gap between the literature recommendations for co-design of user-centred circular offerings and the analysed circularity-related games.

First, most of the analysed games were designed to support learning about circularity, instead of contributing to the development of implementable circular offerings. Yet, the synthesised recommendations stress the importance of supporting the development process. Second, none of the games supported collaboration with stakeholders, which is a key recommendation. Third, most of the games had a very shallow representation of users and users' needs, and none provided support for co-design. However, basing a circular offering on user needs is another key recommendation.

These gaps represent opportunities for games that facilitate circular co-design and experimentation. But, as the recommendations are numerous and ambitious, great care should be taken to make a game that is easy and fun to play. The balance between what to make realistic and what to simplify needs to be well-crafted and the bridge between the game and the real world should be simple, yet effective. With games built on the identified recommendations, we anticipate that companies will be encouraged to create attractive circular offerings that satisfy users' needs long term while contributing to prolonging product lifetimes.

## Acknowledgments

The authors would like to thank Formas, the Swedish government research council for sustainable development, for funding the research project "Game-Based Approaches to Create Innovative Circular Value Propositions", and the project's reference group for contributing valuable input.

# Wellbeing Wardrobe: A wellbeing economy approach for the fashion and textile industry

**Samantha Sharpe[a],Taylor Brydges[a, b],Monique Retamal[a],Rhiannon Pugh[c],Mariangela Lavanga[d]**
a) University of Technology Sydney, Sydney, Australia
b) University of Toronto, Toronto, Canada
c) Lund University, Lund, Sweden
d) Erasmus University Rotterdam, Rotterdam, The Netherlands

**Keywords**: Wellbeing; post-growth; fashion; sustainability; participatory workshop; transformative policy

**Abstract**: The wellbeing economy approach provides a way to reorient our economic systems to focus on human and ecological wellbeing, rather than just economic growth. In this paper we explore how the wellbeing economy approach can be applied to the fashion and textile system to guide and increase the ambition and focus of textile and garment policy in Europe to better enable the sustainable transformation of the sector.

This paper draws on a mixed-method approach. Firstly, we drew together two distinct bodies of literature – wellbeing economics and fashion sustainability – to find intersections and identify common ground as a basis for conversations and practices that take us towards a sector that operates within planetary boundaries and ensures livelihoods and dignity for all those who make and wear clothing. Secondly, we designed and conducted co-creative participatory workshops with different groups of stakeholders, mostly from Europe, to highlight several priority areas for policy interventions.

Policy plays a critical role in supporting the wellbeing economy, through the implementation of limits and thresholds that reduce production and consumption, support for participatory and redistributive processes and mechanisms at local, national, and international levels, and encouraging public debate about the evolution of ideas about business and work. The move away from growth economies to a wellbeing economy will involve multiple pathways, levels, and contexts. The paper concludes by identifying some relevant policy pathways that can be implemented in the short-term, and other transformational and inter-dependent policy opportunities that would require broader support and momentum from the sector and wider community to be pursued.

## Introduction

It is well-established that the fashion industry is environmentally and socially unsustainable (Bick et al, 2018; Brydges and Hanlon, 2020; Buchel et al. 2022; Leal Filho et al., 2019; Niinimäki et al., 2020). The sector accounts for up to 10% of global carbon emissions with business-as-usual projections seeing this grow by a further 50% by 2030 (World Bank, 2019), as well as contributing significantly to pesticide and chemical use, industrial wastewater pollution, microplastics pollution (from synthetic garments) (Palm et al, 2021).

Not only is the production, consumption, and disposal of clothing damaging to the environment, but efforts to repurpose or recycle our garments have been haphazard and inconsistent (Henninger et al., 2017; Sandin and Peters, 2018; Sandvik and Stubbs, 2019). Post consumption textile waste is significant – of the estimated 100 billion garments are produced annually, most ending up as waste, with only 1% recycled into new clothing (Boulton et al, 2022). Clothing waste often ends up in the Global South where there are no resources or facilities to appropriately dispose of it, leading to the pollution of waterways and landscapes (Greenpeace, 2022).

The negative social impacts of the sector are also well documented. Although the rapid growth of the sector has created millions of jobs, mostly for women and in the formal economy - most of this employment is low-wage, work associated with high levels of overtime, poor working conditions, gender inequality and gender-based violence and harassment (ILO, 2021). Forced labour and examples of modern slavery are very prevalent, as well as vast numbers of people in “working poverty” - workers who cannot earn enough income to cover their basic household needs (Anner, 2020).

The sector provides a clear example of the need for system transformation. Whilst contributing significantly to dangerous climate change, biodiversity loss and testing the limits of planetary boundaries, while at the same time not providing stable livelihoods and decent work to the more than 60 million people who work in the sector worldwide.

### *Approach and methodology*

In applying a wellbeing economy approach to the fashion and textile sector, we used a mixed methods approach – starting with a structured literature review at the intersection of wellbeing economies and sustainable fashion and textiles. This review allowed us to generate a conceptual analysis framework of the objectives and principles of wellbeing economies that could be applied to the fashion and textiles sector. This analysis was then extended and validated through stakeholder workshops. Stakeholder were drawn from the fashion, textile and garment sector, post-growth and wellbeing economies communities and policy and supply chain governance stakeholders. Using the conceptual framework stakeholders envisioned a wellbeing economy transformation of the fashion and textile sector – identifying ideas, innovations, and paradigms for a wellbeing economy for fashion and garments. A subsequent stakeholder workshop considered factors that could enable a transition to a wellbeing economy for the fashion and textile industry, including policy and program development, as well as key roles for different actors.

### *Structure of this paper*

The rest of this paper is structured into three sections. The following section provides a short overview of the wellbeing economy approach and the conceptual framing of the approach. This framework is then applied to the fashion, textile, and garment section in Section 3, where policy implications of this are summarised. Section 4 provides conclusions and highlights further gaps and research needs.

## Wellbeing economy approach

There are a range of growth-alternative economic models, including wellbeing economies, doughnut economies, steady-state, post-growth and degrowth, all of which provide a way to pursue human and ecological wellbeing rather than GDP growth. We refer to these growth-alternative models using the term: the wellbeing economy. Although there is some diversity in each approach – several overarching objectives defined the wellbeing economy:

- Focus on reducing the environmental impact of human activities through practices such as reduced material and energy consumption, and more localised economies.
- Support and mechanisms for income distribution, both within countries and globally, through practices such as redistributive income, universal basic income, non-monetary exchange systems and new modes of ownership.
- Transitioning from material and consumption-based societies to more participatory and community-oriented societies through practices such as shorter work weeks, limits to advertising and new ways of recognising unpaid and/or informal labour.

### *Four key principles of the wellbeing economy approach*

In our analysis of wellbeing economy approach, we identified four principles (Sharpe et al, 2022, pp16):

1. **Establishing limits** - Creating a wellbeing economy involves establishing limits on production and consumption and learning to live within these boundaries. These lower and upper thresholds of sufficiency will have different dimensions across the Global North and the Global South. New indicators of wellbeing can guide progress towards satisfying human needs (such as mental and physical health, living and working in dignity, opportunities for community, and political participation) while also supporting ecological health.

2. **Promoting Fairness** - We need to design distributive systems to ensure global and intergenerational equity and redistribute global resources and wealth across diverse contexts and communities.

3. **Just governance -** Participatory and deliberative processes are essential to guarantee that any proposed transition is inclusive and open to debate. The transition to a wellbeing economy will require major system-level changes in many domains. Managing these transitions depends on sophisticated and robust participatory approaches, and on building skills and capacity to ensure a diverse range of participants can contribute. Public dialogue and social movements help to establish momentum for these wider conversations and debates.

4. **New exchange systems -** New business structures and systems are key to providing and exchanging goods and services in ways that do not only depend on overproduction and overconsumption. Creative business exchange models could meet social needs (such as conviviality and reciprocity) and provide meaningful work while also being environmentally regenerative.

## Applying the wellbeing economy approach to the global fashion sector

In recent years, green growth strategies have dominated much of the industry (Armstrong et al., 2015; Pookulangara and Shepard, 2013; Thorpe, 2014). While arguably the strategies have led to some sustainability innovations and efficiency gains, these have been mostly incremental, and fail to address the practices at the core of the industry's unsustainability: the overproduction and overconsumption of clothing.

In applying the principles of wellbeing economies to the fashion, textile, and garment sector we are aiming to identify pathways and sustainability strategies that are consistent with the intentions of a wellbeing economy. In doing so, we aim at finding existing strategies that could be supported and amplified to achieve a wellbeing economy in the sector. At the same time, many existing strategies will be insufficient to achieve the substantial transition needed; in general, there are significant gaps in the capacity and ability of the current sector to operationalise a wellbeing-focused economy.

Given this starting point, Table 1 summarises our assessment of existing sustainability-focused practices in the fashion and textile sector. Previous work showed virtually no current focus on *limiting* fashion production or consumption, nor any significant initiatives designed to encourage living within planetary boundaries (Sharpe et al., 2022). There is therefore a need that new policy and program frameworks (such as the EU Strategy and Regulation for Textiles, Sustainable Product Policy and Eco-design, Circular Economy Policies and EU Trade Agreements) focus on strengthening existing practices that could further enhance the progress of the sector towards wellbeing economies.

We acknowledge that many of the existing sustainability-focused practices in the fashion and textile sector could be placed in multiple categories of our assessment (Table 1), or maybe considered inadequate to the task of making the sector sustainable. Our aim here is to look for diverse pathways to change, take a portfolio approach, and be generous in acknowledging avenues for improvement that could connect existing practices to a new direction. In addition, we also draw links to transformation policy opportunities that would enable the fashion and textile sector to engage with wellbeing economies more meaningfully.

### *Policy context and opportunities for wellbeing economies*

Creating a wellbeing economy will rely on the implementation of widespread, micro and macro level policies, or, in other words, a multi-level agenda of reforms targeting all facets of economic and social life – including fiscal systems, business structures and practices, labour laws and systems as well as social practices and consumption. The scale and breath of the changes required to support a transition away from economic growth towards a regenerative economy need transformational policy.

Current policy developments for supporting sustainable textiles and garments in Europe are mostly focused on optimising and increasing efficiency within the *existing* business model (for instance, through increased design for circularity, recycling and/or using recycled materials). As such, this policy framework does not yet meaningfully engage with the requirements of the wellbeing economy. The analysis presented in Table 1 shows opportunities to enhance linkages with the wellbeing economy in the fashion, textile, and garment sector, both through existing policy but also more transformational policy.

Transformative policy agendas are aimed at addressing societal challenges (such as climate change and the need for sustainability), focus on a broad agenda (rather than narrow single policy problem) and require public organisations and institutions tasked with delivering these policy agenda with new ways of administrative and organisational capacities (Haddad et al., 2022).

Policy plays a strong role in supporting the wellbeing economy, through the implementation of limits and thresholds that reduce production and consumption, support for participatory and redistributive processes and mechanisms at local, national and international levels, and encouraging public debate about the evolution of ideas about business and work. These policies must be developed as a comprehensive agenda, rather than in isolation.
Transformational policy opportunities will require support and momentum from a broad range of the sector actors, organisations and community to be pursued. In many cases these policy interventions are inter-dependent in that they would require implementation in all or most areas to enable change.

## Conclusions

The fashion and textile sector – which currently reflects the dominant economic paradigm of continuous GDP growth and material accumulation – is not working in the interests of the common good. The sector is one of the largest and most globalised industrial sectors in the world and is also one of the most unsustainable, based on both environmental and social metrics. While there have been many fashion sustainability initiatives and campaigns in the past decades, the sustainability transition is slow, and the situation is not improving: the gap between sector growth and sustainability performance is increasing.

The sector urgently needs new ideas, operating models and procedures, as well as an entirely new economic philosophy. The aim of our research has been to start envisaging a new post-growth direction for the fashion and textile sector. We have called this vision the Wellbeing Wardrobe: imagining and designing a future sector that operates within planetary boundaries and ensures livelihoods and dignity for all those who make and wear clothing.

## Acknowledgments

The authors would like to thank Emily Macintosh (European Environmental Bureau), the Advisory Panel in our research (Kate Fletcher, Mathilda Tham, Jennifer Hinton, Ed Langham, Xubiao Zhang, Aileen McLeod and Timo Rissanen), Rachael Jackman, Rebecca Cunningham, and the participants of our stakeholder workshops for their valuable contributions.

# Circular Consumption of Household Water: A Critical Literature Review

**Sikhwal, R K[(a)], Aurisicchio, M[(a)]**
a) Dyson School Design Engineering, Imperial College London, United Kingdom

**Keywords**: Household water; Circular water consumption; Circular economy; Water conservation; Water value chain.

**Abstract**: Water is a critical resource that addresses one of the most basic human needs and facilitates major activities. Water is, however, increasingly becoming a scarce resource. The majority of efforts to reduce water stresses have focused on water sourcing, distribution, consumption and treatment in industry applications. Water consumption in the home has comparatively received little attention. Although some work in this area exists, it is sparse. This research reviews the literature on water consumption in the home to synthesise current knowledge and understand how a circular economy approach might be leveraged to mitigate the challenges posed on water value chains. The review frames household water consumption within the whole water journey. A proposal is put forth detailing how the CE strategies (i.e. narrowing, slowing down, closing and regenerating) can be employed in the context of household water consumption. The review identifies multiple drivers of water consumption in the household highlighting the need to give due consideration to contemporary consumption determinants such as climate drivers and micro-activities of water consumption. The review identifies the importance of water use behaviour and provides a critical analysis of water interventions in the home at policy, behaviour, infrastructure, and digital technology level stressing the need for better coordination between different interventions. Finally, the review provides a thesaurus of studies which can help stakeholders involved in household water value chains and future researchers to better understand issues about household water.

## Introduction

Out of the 1351 million km$^3$ of water on earth (Winpenny et al., 2010), only 3% is available as freshwater resources suitable for drinking and irrigation (European Commission, 2018). From 1960 to 2014 the water demand increased by 100% in the agriculture sector, 300% in the industrial sector and 600% in the domestic sector (Otto & Schleifer, 2020; World Resources Institute, 2023). At the same time, grand challenges such as climate change, population growth and urbanisation are increasingly depleting our available water levels, making water availability a topic of concern (Poff et al., 2016).

As a result of the scarce availability of water and the increasing consumption demand, half of the European countries are facing water stress (Bixio et al., 2006). The UK National Framework for Water Resources estimates that if further action is not taken, 3.4 billion additional litres of water per day will be required between 2025 and 2050 to meet future demand for public water supply (Environment Agency, 2022). Water stress comes with consequences such as reduced food security and difficulties in maintaining a variety of water supply sources along with increased societal disruption (Postel et al., 1996).

Most efforts to reduce water stress have focused on water sourcing, distribution, consumption and treatment in industry applications. One area which has comparatively received little attention is water consumption in the household. Events like Cape Town's 'Day Zero' (Bischoff-Mattson et al., 2020; Enqvist & Ziervogel, 2019; Visser, 2018) have resulted in highly publicised conservation measures, usage restrictions, re-allocations and actual interruption of essential water services, demanding for better understanding of household water consumption.

Understanding water consumption in the household is key as it offers the opportunity to better plan for water consumption and make effective utilisation of water (Van Weelden et al., 2016). Current attempts to understand and intervene in water consumption in the household are sparse and disjoint. Further, they have mostly been undertaken from a linear economy perspective (Aldaya et al., 2021; Gleick, 1996; Linkola et al., 2013). Taking a circular economy perspective on water usage in the household requires looking at circular consumption which is one of the critical enablers of the transition to a circular economy (CE) (Kirchherr et al., 2017; MacArthur, 2013; Rizos et al., 2017). The notion of circular consumption is in line with the United Nations Sustainable Development Goal 12, which envisages the attainment of 'Sustainable consumption and production' patterns (United Nations, 2016). Although circular consumption had been studied in a range of different contexts, a comprehensive account for household water is lacking.

Overall, this review aims to bring together literature on water consumption in the household environment to synthesise current knowledge, understand how a CE perspective could be leveraged to mitigate current challenges and identify important gaps and opportunities for future research.

## Material & Methods

This paper aims to bring sparse and isolated literature on various elements of household water consumption together to support the development of new understanding of the topic. The systematic literature review was conducted following the three steps described by Tranfield et al. (2003).

In the first step, the keywords and phrases used in the review were identified based on the objectives and scope of the review. The keywords keep the consumption of water at the centre with different associated dimensions of consumption included, as follows:

- Consumption of water;
- Consumption in the home;
- Consumption objectives: lean, sustainable, circular.

Scopus was initially used as the academic database. Google Scholar was also used to find practical work which might not be included in traditional academic literature. To limit the number of publications, abstracts were screened, and some publications were excluded as they dealt with topics not central to the review such as smart home monitoring and environmental assessment. As a result, 147 publications were identified.

In the second step, shortlisted publications were analysed using the following five dimensions: Problem addressed, Theoretical frameworks, Methods & tools, Issues, and Research Gaps (Camacho-Otero et al., 2018). These dimensions were only used to extract key topics. In particular, a double-cycle coding technique (Saldaña, 2021) was employed to identify and group the topics putting emphasis first on descriptive coding and then on pattern coding.

In the third step, the results from the identification and analysis of the topics were presented and discussed in terms of system perspective (journey of household water), consumption determinants, water use behaviour and conservation interventions.

## Results

### *The Journey of household water in the whole system*

The analysis of the literature led to the development of the household water journey presented in Figure 1 including four phases. Household water consumption (Phase 3) precedes water sourcing (Phase 1) and water filtration and distribution (Phase 2) and follows wastewater treatment (Phase 4).

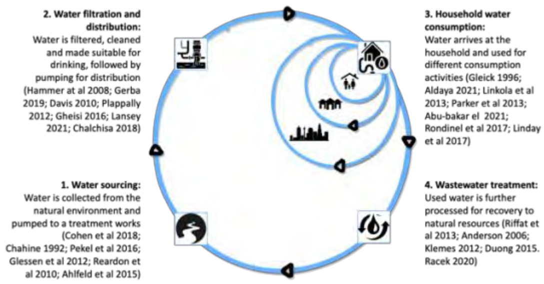

**Figure 1. The four phases of the household water journey.**

Focusing on household water consumption, it can be seen that addressing this phase may involve investigating and intervening on the household, neighbourhood, city and region, see Figure 1. Current work has primarily investigated the neighbourhood level (Bouziotas et al., 2019) and city level (Kakwani & Kalbar, 2020; Mbavarira & Grimm, 2021), neglecting or touching only peripherally water consumption in the household. This research focuses on the household level where, with exceptions (Alarcon et al., 2021), the majority of current literature has addressed water consumption within a linear rather than a circular system (e.g., Aldaya et al. (2021); Linkola et al. (2013)). Addressing the circularity of water in the domestic setting requires considering four CE strategies, namely narrowing, slowing down, closing and regenerating. These circular strategies have been investigated for the flow of material resources in products (Merli et al., 2018), while the flow of water has been researched through the CE principles (Bouziotas et al., 2019; Kakwani & Kalbar, 2020; Mbavarira & Grimm, 2021). However, in the context of household water consumption, there is a need to rethink and redefine the strategies and explore their utilisation.

Narrowing the water flow involves using less water per task. It can take place at the supply side when the water provided to consumers is reduced (e.g., controlling the water flow at the main supply line), see Figure 2. But, narrowing can also occur at the use side, when water usage is avoided (e.g., vacuum toilet) or less water per task is used (e.g., reducing water through aerators or adjusting the water flow), see Figure 2. To narrow the flow, water usage can also be optimised. Slowing down the water flow involves extending the useful life of water over multiple tasks (e.g., cascading water from the tap to the toilet). Closing the water flow entails home-centred treatment of post-usage water for reuse in the same or a new task. It can take place through either reconditioning, which involves partial treatment of greywater before using it again, or recycling which involves purifying greywater before using it again. Finally, regenerating the water flow involves resorting to alternative sources of household water supply (e.g., roof rainwater harvesting systems for household water supply) and replenishing or restoring the water supply.

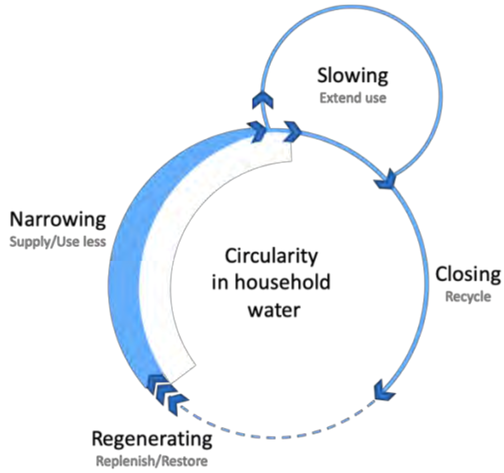

**Figure 2. Four circular strategies for water consumption in the household.**

*Determinants of water consumption*

Household water consumption is influenced by multiple drivers. Table 1 presents the drivers identified in the literature based on two dimensions, namely direct or indirect influence and global or local effect. The local drivers represent individual, household and community level factors, whereas the global drivers cover societal, national and international factors. The drivers that are local and with a direct influence on household water consumption have been widely investigated (Arouna & Dabbert, 2010; Davies et al., 2014; Gregory & Leo, 2003; Jorgensen et al., 2009; Lindsay et al., 2017; Mayer et al., 1999; Morote et al., 2016; Reynaud et al., 2018; Rondinel-Oviedo & Sarmiento-Pastor, 2020; Syme et al., 2004; Xue et al., 2017). The drivers that are local and with an indirect influence have been mainly studied from water supply and demand management perspectives (Gaudin, 2006; Rajapaksa et al., 2019; Reynaud et al., 2018). When it comes to the drivers that are global, these have been investigated as standalone factors as for example the influence of higher living standards on household water requirements (Syme et al., 2004; Willis et al., 2013). The joint investigation of global and local drivers is key to look at a complete picture of household water consumption. Furthermore, empirical studies showing the impact of these drivers on household water consumption are limited and there is an opportunity to further study them.

| | Global Effect | Local Effect |
|---|---|---|
| Direct Influence | **Living standards** (Syme et al, 2004; Willis et al 2013) **Cultural factors** (Kim, S H 2007) **Seasonality** (Reynaud A, 2018; Rathnayaka et al., 2015) **Global diet** (Vanham et al, 2018) | **Household habits** (Gregory G D et al, 2003; Jorgensen B et al, 2009; Rondinel et al 2020; Lindsay et al 2017) **Household demographic** (Arouna et al, 2010; Reynaud A, 2018; Xue et al., 2017; Davies, K 2014) **Size of housing and outdoor space** (Morote et al 2016; Syme et al, 2004; Mayer P W et al 1999) **Home water activities** (Fonseca-Santos et al. 2015; Carragher et al., 2012; Zhang and Brown, 2005; Gato-Trinidad et al., 2011) |
| Indirect Influence | **Urbanisation** (Liu J et al, 2022) **Population growth** (Xiangmei, M, 2021) **Climate** (Stoler J et al, 2021; Gosling S N et al 2016; Qin P et al 2022) | **Price** (Gaudin S, 2004; Reynaud A, 2018; Rajapaksa et al, 2019) **Monetary incentive** (Rajapaksa et al, 2019) **House typology** (Bich-Ngoc et al 2019; Arouna et al, 2010) |

**Table 1. Household water consumption drivers with respect to their influence and effect.**

One of the main local drivers is water-based activities in the home. Key domestic water usage activities (also called in the literature water end uses (Shan et al., 2015)) are, for example, showering, toilet flushing, gardening and swimming pool filling (Carragher et al., 2012; Fonseca-Santos et al., 2015; Gato-Trinidad et al., 2011; Zhang & Brown, 2005). Empirical data on water usage activities from seven key studies are summarised in Figure 3. It is worth noting that these studies attributed a varying amount of water usage to different home consumption activities. Among others, this could be due to the geographical location of the area studied, and the type of metering mechanisms implemented. Figure 3 shows that in some studies (1, 2, 7) the main contributors to water consumption were the 'shower', 'toilet' and 'washing machine' though in different order of relevance, while in others (3, 6 and 4, 5) the 'tap' entered this triad to replace the 'toilet' or the 'washing machine'. Notably, the 'dishwasher' plays always a minor role.

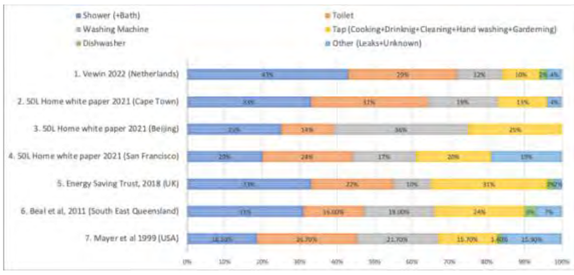

**Figure 3. Home activities involving water usage.**

### *Water use behaviour*

Addressing household water consumption remains incomplete without due attention to behaviour practices (Chu et al., 2009; Kontokosta & Jain, 2015; Suero et al., 2012). While some studies investigated water use behaviour from the perspective of user interaction, others conducted in-depth behavioural analysis. Individual conservation efforts and environment beliefs have been found to influence water consumption in the home and community (Aprile & Fiorillo, 2017; Clark & Finley, 2007; Corral-Verdugo et al., 2003; Fan et al., 2014; Gregory & Leo, 2003; Hurlimann et al., 2009; Sønderlund et al., 2014). Gilg and Barr (2006), conducting a study of 1265 households in Devon (UK) concluded that committed environmentalists and mainstream environmentalists were most likely to engage in water-saving activities regularly. Water-saving efforts can also negatively affect consumer water behaviour, a phenomenon known as the rebound effect. Inman and Jeffrey (2006), for example, found that consumers took longer showers and consumed more water after having installed water-saving devices at home.

### *Water conservation interventions*

Literature on water conservation interventions was found to focus on policy, behaviour, infrastructure and digital technology as summarised in Figure 4.

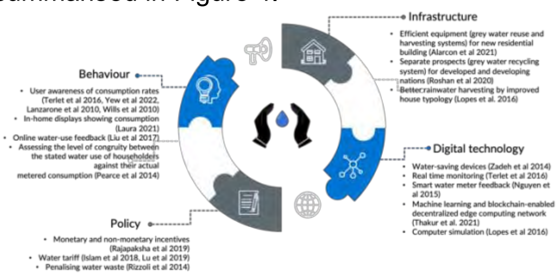

**Figure 4. User-centric conversation interventions.**

Policy interventions seek to influence water consumption through regulations, economic instruments and appeals to individuals' environmental consciousness mainly narrowing the flow of household water. They are based both on using monetary (e.g., price, consumption tariffs) (Ghimire et al., 2016; Islam & Duraman, 2018; Klaiber et al., 2014; Olmstead & Stavins, 2009; Rajapaksa et al., 2019; Ratnasiri et al., 2018; Wichman, 2014; Zhao et al., 2016) and non-monetary measures (e.g., water use restrictions, penalising water waste) (Renwick & Green, 2000; Rizzoli et al., 2014).

Behaviour interventions target changes in consumer behaviour to influence water consumption mostly narrowing and slowing the flow of household water. One of the key behaviour interventions is to facilitate knowledge of water scarcity and management practices. For example, among UK water supply recipients increased knowledge was shown to be effective in a 5% reduction of water use (Howarth & Butler, 2004). Other mechanisms are based on individual conservation efforts and attitudes (Gilg & Barr, 2006; Lucio et al., 2018; Maas et al., 2017; Sønderlund et al., 2016; Steg & Vlek, 2009; Syme et al., 2004).

Infrastructure interventions tackle all the strategies to create a circular flow of household water. Among others, there are interventions to install water-efficient appliances (Inman & Jeffrey, 2006; Turner et al., 2004), greywater reuse in activities such as gardening, new greywater recycling models (Roshan & Kumar, 2020), and alternative water sourcing (Lopes et al., 2016).

Digital technology interventions focus on the role that data can play in influencing water consumption narrowing and slowing the flow of household water. The new insights obtained from smart metering supported by the latest technological advancements provide an opportunity to promote more efficient water consumption via the provision of detailed customised water-use information to consumers (Adeyeye & Church, 2012; Davies et al., 2014; Liu et al., 2013; Tian & Chen, 2022).

Figure 5 summarises how policy, behaviour, infrastructure and digital technology interventions are associated to the four circular strategies.

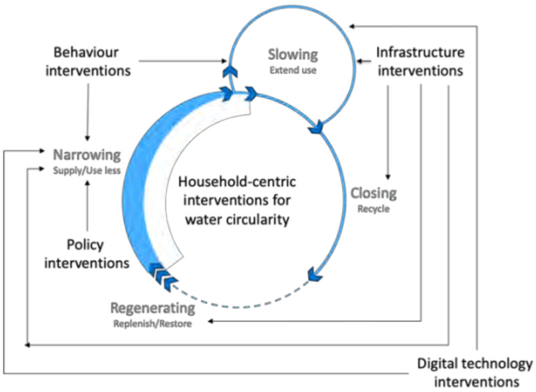

**Figure 5. Household-centric conversation interventions addressing the four circularity strategies.**

## Discussion

Employing circularity principles in the consumption phase of the household water journey is key to enable sustainable water management. Extending previous research on CE strategies for material flows (Merli et al., 2018), this work conceptualised the applicability of CE strategies (i.e. narrowing, slowing down, closing and regenerating the resource loops) to household water. This provides a more strategic and systemic approach to investigate, develop, and implement circular solutions and practices contributing towards a future where water is sustainably available.

Current drivers of research on water consumption are centred on macro and micro socio-economic factors but neglect more pressing and contemporary aspects such as climate change. There is a need to look beyond the large-scale climate-influenced determinants (e.g., intermittent water supply) triggered by extreme weather situations such as droughts, storms, or floods (Gosling & Arnell, 2016; Stoler et al., 2021). Climate change and associated water supply restrictions, resulting in different consumption patterns for consumers require more consideration. Previous work in the area of household water insecurity (HWI) (Broyles et al., 2022; Young et al., 2021) can be used as a tool to study the implications of climate drivers on household water consumption. As climate drivers might lead to changes in water availability and provisioning, HWI can be used to direct efforts to manage household water demand.

Bathing, showering, dishwashing, laundry and gardening are macro-activities of household water consumption widely investigated (Carragher et al., 2012; Fonseca-Santos et al., 2015; Gato-Trinidad et al., 2011; Zhang & Brown, 2005) but with limited quantification of water usage. Hand washing, grooming and oral care are micro-activities of household water consumption that have either been neglected or poorly investigated, possibly due to the perception of limited water usage. Overall, there is a need to undertake more empirical research on micro-activities and quantitative studies on water usage during both macro- and micro-activities. It can facilitate a more proactive approach to water demand management and has the potential for the development of intervention strategies for sustainable water consumption in households.

Water conservation interventions address the policy, behaviour, infrastructure and digital technology levels. Current interventions are growing but are still isolated and sparse. They support circularity strategies to different extent and are often employed in isolation. There is a need to develop more coordinated and multi-level interventions bringing together whole lifecycle stakeholders for example through collaborative platforms such as 50L Home (50L Home White Paper, 2021). This will also enhance water conservation by addressing more specific water usage areas and achieving more granular water conservation awareness.

## Conclusions

The current water crisis and reducing availability of fresh water calls for a better understanding of how water is consumed in the household environment. The majority of studies in this space were conducted keeping the linear economy system in perspective. This paper reviewed the literature in the field of household water consumption to better understand existing work and how it addresses the requirements to shift towards a CE system. The review frames water consumption in the home within the whole water journey and identifies multiple drivers of water consumption in the household. A proposal is put forth detailing how the CE strategies can be employed in household water consumption. The review highlights the need to give due consideration to contemporary consumption determinants such as climate drivers, micro-activities of water consumption and better coordination between different conservation interventions in the household environment. It also identifies the importance of water use behaviour and provides a critical analysis of water interventions in the home at policy, behaviour, infrastructure, and digital technology level.

# From Soil to Garment: Missing Links in the Assessment Criteria of Textiles

**Else Skjold**[a], **Jesper Richardy**[b]
a) the Royal Danish Academy, Copenhagen, Denmark
b) the Royal Danish Academy, Copenhagen, Denmark

**Keywords**: Longevity; Textiles; LCA Analyses; Circularity; Agroecology.

**Abstract**: The EU textiles strategy of 30th of March 2022 is set to be implemented within a 5-year period. In the strategy, it is the ambition to build a sector wherein '*Consumers benefit longer from high quality affordable textiles' (European Commission 2022)* within 2030. It is particularly these elements of the EU strategy that this paper comments on, with a particular focus on the environmental impact in the beginning of the lifecycle of plant-based textile fibers, and how these affects longevity-related properties in the use phase.

The paper elucidates discrepancies between assessment criteria within agriculture and textile certification schemes and highlights consequences of these in relation to firstly, how textiles are assessed today, secondly, how assessments are being understood and practiced within industry (here in Denmark), and thirdly, what this means for longevity of textiles. Through interviews with seven textile sourcers and advisors on sustainable practices in the Danish textile industry we examined how industry insiders understand and evaluate environmental risks in their materials supply base and how they are addressing these risks. The interviews highlighted major knowledge gaps within the textile industry when it comes to encouraging sustainable practices at the beginning of the supply chain and a profound lack of linking various assessments of parameters such as environmental impact, fiber quality and durability, and hereby a deeper understanding of what a low-impact and long-lasting fiber really is.

## Introduction

This paper represents preliminary insight from the project 'Regulation and Promotion of CE' that is affiliated with the Danish research partnership TRACE (trace-im4.dk). A politically funded platform for circular economy (from here: CE) within plastics and textiles initiated on the basis of a EU commitment to support mission-based research, as argued by Mazzucato (2019). One of the key ambitions of the TRACE partnership is to respond to the European strategy for plastics in a circular economy (European Commission 2018), and the EU strategy for sustainable and circular textiles (European Commission 2022). In this paper we will look into the EU textiles strategy and critically ask what kind of CE is proposed, and how we as researchers can position our work accordingly. As there are many issues addressed in the strategy, we will focus mainly on the following passage of text:

*"By 2030 textile products placed on the EU market are long-lived* […] *produced in respect of* […] *the environment. Consumers benefit longer from high quality affordable textiles" (European Commission 2022).*

For doing so, we would like to enquire what type of CE understanding is currently underpinning EU regulation. We here lean on the critical analysis of EU directives-, strategies-, and legislative documents for promoting CE in the period of 2011-2022 by (Alberich, Pansera, and Hartley (2023). Here, the documents are analyzed by means of the 'four futures of circularity' model by (Bauwens et.al (2020), on the basis of which the authors conclude that most documents are based on a *circular modernism* which relies heavily on technology development and (linear) growth based on circular business models and decoupling of resources, and to an increasing extent *planned* *circularity* in which regulative instruments such as taxes, hard caps and bans incentivize more circular practices between production and consumption. However, more deep-rooted views on circularity that might concord with planetary boundaries such as formulated by Desing et al. (2020) are not in play at all. In this terminology, that would be a *peer-to-peer circularity* which drives on the development of technology that can foster circular sharing economies, or *bottom-up sufficiency* in which de-centralised, locally based and small-scale production aims at supporting local needs. The authors conclude that current EU policies for CE are promoting 'technocratic and productivist narratives based on a weak form of circularity' (Alberich, Pansera, and Hartley 2023). It could therefore be argued, that environmentally sound circular futures such as those suggested in early writings like *Silent Spring* (Carson, Darling, and Darling 1962) and *Small is Beautiful (Schumacher 1973)* or the more recent Earth Logic report (Fletcher and Tham 2019) are not currently being stimulated in EU policy.

Heikkilä et. al, (2018) propose that a CE builds on a user-led and eco-systemic partnership model consisting of many stakeholders that together uphold resources at the highest possible level by stimulating long use phases, resale, services for maintenance, mending and repair, and various textile technologies for repurposing. As the EU textile strategy suggests, such a system would have long-lived and high quality textiles as its prime medium for it to work. Looking back in history there are many examples of what might be understood as circular economies, as for example the 18th-and 19th Century Japanese Boro culture where textiles were so heavily regulated that even smaller scraps of used textiles generated a high value, and therefore needed to perform well throughout all its possible lives (Price and Tebelius 2021).

As this conference addresses 'product lifetime and the environment', an important question we need to ask is how terms such as 'high quality' and 'long-lived' are defined and assessed, and what type of data would be needed to underpin them. We here follow the concept of 'technical longevity' defined by Hasling and Ræbild (2017) that focus on technical properties of fibers such as tensile strength. While there is a growing scholarly debate on how to build data for promoting longevity in the use phase (see, for example Wiedemann et al. (2020), this paper will highlight how a comprehensive body of data, primarily from agriculture, is missing from textiles LCA assessment schemes and are also not included in textile assessment schemes and certifications. This is important, as it is estimated that 31% of all textiles derive from agriculture (Textile Exhange 2022). Through qualitative interviews with 8 leading sustainability consultancies in Denmark, we have investigated what this has of consequences for the way these assessments guide industry, and what effects this might have on longevity and quality of textiles.

## Methodology

For the literature study of agricultural production methods, sustainable practices and agricultural LCA methods, as well as assessment criteria for the most widely used certification schemes, cited literature within was found using Web of Science and reports available online. Insights into data availability and LCA model functioning was supplied by Ecoinvent (World Food LCA Database 2017; Nemecek and Schnetze 2011).

Informed by these issues seven semi-structured qualitative interviews were conducted May-October 2021 with Danish gatekeepers of sustainable sourcing of textiles; Respondents were sourced through snowballing within the Danish network of fellow researchers, trade organizations, and innovation networks. Six of these are consultants who work in leading Danish sustainability agencies- and organizations. The 7th interview is conducted with a Danish representative of the European Environment

Agency who is actively engaged with developing and implementing EU directives in the area of textiles. Interviews were recorded on Zoom on the basis of remote HCI research methods and transcribed subsequently (MacLeod et al. 2017). Permission was provided to record all interviews on the condition that all statements were made anonymous.

Interviews were semi-structured and built on laddered dialogue, or what Kvale and Brinkman have named 'conversation as research' (Kvale and Brinkmann 2015). All interviews were opened with more informative questions where respondents presented themselves and their agency/organization. Selected themes for the second sequence were 1) how do they work with risk assessment in the production chain, and where do they place particular focus, preferably visualized (respondents displayed PowerPoints from their presentation material, or would draw the production chain on a paper and show on the screen), 2) plant fiber production - what parameters are included in their risk assessments i.e. carbon capture, biodiversity losses, soil management etc.

The third sequence worked as a summation of the issues discussed. In the following order, questions were 1) what are the biggest issues or risks with regards to plant fiber production and sustainability consultancy (respondents were provided with a line of possible areas such as transparency, resources/cost, qualifications, regulation etc.). 2) what types of knowledge would be beneficial for them to have collected, as a way of assessing the development of the parameters discussed, 3) what types of systemic barriers they see as main focus areas of future research in sustainability and textiles, with particular impetus on plant fiber production.

Subsequently, the empirical data was interpolated up against the parameters of leading textile assessment schemes, as well as data from the literature study.

## Impact assessments; Between agroecology and textiles certification schemes

Textile industries rely on certifications or life cycle analysis (LCA) to monitor and evaluate their environmental footprint. The certifications, however, do not address the complexity of agricultural sustainability beyond the dichotomy between organic and conventional systems.

LCAs pull data from a range of life cycle inventory (LCI) databases, such as Ecoinvent and The Environmental Footprint (EF) database on the environmental impact of a wide array of products, services and processes. LCA's are the basis for the publicly available Higg Material Sustainability Index (MSI) and The Product Environmental Footprint (PEF) – which is the EU's method of calculating a product's environmental footprint (Sandin, Roos, and Johansson 2019).

The processes which can be modelled in LCA are ozone depletion, acidification, freshwater eutrophication, marine eutrophication, human toxicity, photochemical oxidant formation, particulate matter formation, terrestrial eco-toxicity, freshwater eco-toxicity, marine eco-toxicity, ionizing radiation, urban land use, and fossil energy consumption (Fan et al. 2022). However, some key aspects of sustainable agriculture, such as better soil health and biodiversity, are largely ignored in current LCA methods (Sandin, Roos, and Johansson 2019).

Several papers have revealed issues within the current use of LCA's as the main tool used to account for sustainability in plant fiber production and thereby textiles (Fan et al. 2022; Wiedemann et al. 2020; Watson and Wiedemann 2019; van der Velden, Patel, and Vogtlander 2014; Sandin, Roos, and Johansson 2019; Roos et al. 2016). The models used often a) generate data which don't account for spatio-temporal differences which are particularly evident in fiber production systems and third scope impacts, b) evaluate a limited range of impact categories which do not account biodiversity losses and ecosystem functioning (Fan et al. 2022), c) there is more validated data available for some processes than others, some are completely missing, d) there is generally no or little information about the uncertainty of data (Sandin, Roos, and Johansson 2019), e) there are transparency issues as many of the datasets in life cycle inventory databases are protected behind a payment wall and not accessible to the scientific community. Therefore, more research is needed to include more operational indicators and a broader perspective of agricultural multi-functionality towards a better representation of plant fiber production than is currently the case in LCA methodologies.

Another method textile sourcers use to estimate the environmental impact of a textile is by using textile certifications. Some certification schemes are very specialized in a particular area of the textile supply-chain. For instance, the SA8000 certification covers labor rights in manufacturing processes ("SA8000 Certified Organizations - SAI" 2021), while other certifications (i.e. B-corp) cover more parameters and processes (B-corps 2021). Some certification schemes seek to monitor and validate sustainable agronomic practices. Only one certification scheme (ROC) monitors agricultural production practices beyond the organic vs. conventional dichotomy. Codex Alimentarius Guidelines and IFOAM Basic Standards provide a minimum baseline for national and regional organic production standards worldwide, but required management practices differ greatly according to national organic standards and are not required to obtain GOTS and Swan label certifications (Varin and Guzmán 2019). For instance, 41% of organic cotton farmers in India use reduced tillage in their soil management, in comparison with only 17 % in African countries (Textile Exchange 2021).

Lastly, and perhaps most important to definitions of technical longevity of fibers, agricultural cultural practices and growth conditions can not only have immediate detrimental effects on ground, - and surface water quality, soil health, biodiversity and carbon emissions, but they also affect fiber quality. Tenacity, length, length uniformity, short fiber content and fineness of constituent cotton fibers are all influenced by soil and crop management (Bednarz et al. 2004; Majumdar 2011). For instance, reduced soil disturbance (i.e. tilling) increases the organic matter fraction in the topsoil layer thereby both sequestering carbon and increasing the soils water holding capacity. It has previously been shown that water-stressed plants produce fibers with reduced length and uniformity. Therefore, reducing soil management such as it is done in regenerative agriculture might have a positive effect on fiber quality, thereby increasing the longevity of the finished product. Taking fiber quality into account when estimating the environmental footprint of agronomic practices could potentially affect how these practices 'score' when evaluated, for instance in an LCA. None the less, no papers linking agricultural sustainability and fiber quality could be found (Islam, Perry, and Gill 2020).

As such, it can be concluded that current assessment schemes for textiles such as LCAs and certifications do not take into consideration the huge negative environmental impact that natural fiber feedstock production has on soil, biodiversity, and other very important climatic parameters. Neither are vital parameters for the quality of fibers deriving from soil and growing conditions included. In the following, we will showcase what effect this has on industry practices today in the local site of Denmark, based on empirical data from leading sustainability consultancies.

**Table 1. Interviews with sustainable textile advisors.**

| | Advising | Advising on | Evaluation method | Agronomic background | Systemic issues |
|---|---|---|---|---|---|
| **Consultant A** | Small and medium sized fashion companies | Design processes<br>Risk management<br>Certifications<br>Choice/variety of materials | Certifications<br>Gut feeling.<br>Fiber level comparisons | No | Need for agronomic data<br>Outsourcing conflict<br>Size and width of collections |

## Industry practices; a qualitative dive

The interviews highlighted both structural issues and surprisingly large knowledge gaps when dealing with risk assessment in agricultural systems (Table 1). With no educational or practical background in evaluating agroecosystem sustainability parameters and their influence on price and quality, consultants relied heavily on the evaluations provided by a range of certification systems.

All respondents were surprised to learn that organic cotton production was a national standard and that requirements were not established by GOTS but vary between countries. Furthermore, while some respondents were aware that organic cotton production does not address several important issues in fiber production (i.e., carbon sequestration), they were unsure about what parameters to monitor, how to monitor them, and how to set goals for improvement. Three respondents frequently advised clients to limit the number of different textiles used in collections and to limit the number of styles per collection. One respondent relied mostly on LCA analysis for recommendations on fiber sourcing. While realizing that the scope of LCAs were limited and that the underlying data may or may not be correct and up to date it was simply "the only tool available".

Realizing that they do not have the size and expertise to conduct field experiments themselves, several respondents expressed a need for validated data and guidelines be produced and developed by research institutions.

## Discussion, Conclusions and further Perspectives

The interviews reveal that many of the production choices which are made in plant fiber production are not clear to designers and sourcers. Instead, textile industries rely on LCA's or certifications like GOTS, OEKO-Tex, and B-Corp to monitor and evaluate their environmental footprint. Neither LCA's or certifications, however, address the complexity of agricultural sustainability beyond the dichotomy between organic and conventional systems. More and updated data on several impact categories is needed along with more sophisticated models and regulation of best practices in order to increase agricultural sustainability in plant fiber production.

This study looked at plant-based fiber feedstock for textiles that represents 31% of all textiles production today. It reviewed LCA measurement methods from eco-agriculture up against current LCA's on textiles, textiles certification schemes, and best practice for guiding industry showcased by interviews with local gatekeepers in Denmark. The study revealed that the LCA schemes that currently underpin the environmental assessment behind the EU textile strategy is not compatible with planetary boundaries, as they do not take into consideration the situated and contextual interconnection between soil, climate, and fiber. If they did, assessments and indeed future EU regulation would point towards a CE defined by Bauwens et al as *bottom-up sufficiency (Bauwens, Hekkert, and Kirchherr 2020)*in which de-centralised, locally based and small-scale production would support local needs rather than feed into the existing linear growth economy. Going forward, assessment schemes are needed which can inform more systemically, and for example take into consideration how to limit the scale and volume of the resource uptake of raw materials by the industry of today. Furthermore, neither LCA's nor certification schemes on textiles currently take into consideration urgent agricultural parameters that effect fiber performance – and as such – what needs to be assessed if we indeed are to further 'long-lived' and 'high quality' textiles going forward.

# How to promote product life using the European Digital Product Passport?

**Esben Bala Skouboe[a], Søren Løkke[b], Louise Møller Haase [a,b]**

**Keywords**: Design durability, Digital Product Passport, Circular Economy, Product Attachment, Sustainable consumption.

**Abstract:** The Circular Economy (CE) is gaining increasing attention due to the need to reduce waste and promote sustainable consumption. The European Commission has proposed a Digital Product Passport (DPP) to support this goal, providing product-specific information such as components, materials, and repairability to promote transparency and inform consumers about the environmental impact of their purchases. Various experiments, including the Battery Identity Global Passport and Materials and Resources Passport, have been conducted since 2020. To enhance the DPP concept, Plociennik et.al. have proposed a dynamic, cloud-based Digital Lifecycle Passport (DLCP) to quantify and report the environmental impact and natural resource use throughout a product's entire lifecycle. While research in this field has largely focused on end-of-life phases, this article explores literature on product longevity, and product attachment to develop a sub-model that strengthens the relationship between manufacture, product and user, ultimately postponing product obsolescence.

While DPP and DLCP passports will not lead to a closed loop of renewable energy and reused resources, they will promote transparency and encourage more sustainable choices. Overall, the implementation of the Digital Product Passports has the potential to significantly impact sustainability efforts, and the proposed sub-model for Product Longevity represents an important step towards supporting the product responsible to promote product longevity and thereby reduce waste and overall consumption due the increased product care.

## Introduction

To close the loop in the Circular Economy (CE), reduce waste, and support consumers to navigate into more sustainable consumption the European Commission has decided to implement a Digital Product Passport (DPP). (EU 2020) The DPP is product-specific data that contains information on the components, materials, chemical substances, repairability, spare parts, or proper disposal of a product. (Adisorn 2021). This certificate will help recyclers to know which materials and components to expect, and help consumers get more informed about the environmental impact of their purchases. Since 2020, the EU has conducted DPP experiments in various product categories. Ex. Bai et. al suggests a Battery Identity Global Passport (Bai et. al 2020), making It mandatory for all batteries sold in the EU by 2026 to have an accessible online data structure linked with the physical battery via a QR code. The Battery Identity Global Passport will e.g. contain information about the capacity, lifetime, and presence of hazardous substances. Existing initiatives include a Materials Passport (EU 2021) and a Resources Passport (EU1 2021).

Plociennik et.al. (2022) proposes to extend the static DPP with a dynamic, cloud-based Digital Lifecycle Passport (DLCP). The DLCP is a standardized protocol based on an open cloud-based platform that allows different stakeholders along the lifecycle of the product to read and write content to the passport. It quantifies and reports the environmental impacts and natural resource use considering the entire lifecycle of a product. Opening the DLCP for input from different stakeholders challenges data-integrity which needs to be addressed in future research. Current research in the field of DPP and DLCP is dominated by production, material, and environmental science focusing on the end-of-life phases of a product, leaving product life-prolonging information as "metadata" described in the Asset Administration Shell data infrastructure. (Plociennik et.al. 2022). Details, legislation, and data structures are yet to be defined, and it is not clear if the DPP will have one standard or specific rules depending on product categories. Existing passport experiments are still on a conceptual level and not ready for implementation.

This field of work has become increasingly important due to its recycling capacities and transparency to consumers. However, believing in a closed loop of renewable energy and predominantly reused resources is a dangerous illusion because there will always be a certain amount of unavoidable dissipation (Ciacci et al. 2015). This article visits literature in the field of circular product design, product longevity, and product attachment to qualify overseen data types and interaction points beyond the end-of-life operations in recycling and waste sorting. In the following, we will extend the DCLP, with specific inputs to a new sub-model that goes beyond traceability and transparency to strengthen the relationship between product and user and support product longevity, and ultimately postpone the date of product obsolescence.

## Emotional durability

Slowing and narrowing product circles is a key focal point in the circular economy (Bocken 2016, Kristensen & Remmen 2019). From a circular product perspective, recycling is the least preferred option given because it involves the destruction of a product's integrity (Den Hollander et al. 2017). This is because perceiving the product as waste from the beginning, reduces the product's meaning to its material level, potentially destroying product integrity (Den Hollander et al. 2017, Bakker & Hultink 2017). According to research in eco-design and circular design (Van Nes 2003, Mugge et al. 2005, Schifferstein et al. 2005) products with low integrity, have a significantly lower life, due to the lack of attachment and commitment to repair and care for products compared to products with high product integrity. Keeping products alive is not merely a matter of physical durability but also emotional durability (Oswald and Reller 2011, Bayus 1991, Van Ness 2003).
A product's lifetime is not only influenced by its ability to remain durable or functional but also by the user's behavior and perception of it (Cooper 2004, Van Ness 2003).

The challenge of product obsolescence has given rise to several strategies for addressing the user-oriented aspects of product longevity. These strategies include design for attachment, design for emotional durability, and design for trust (Chapman 2005, Mugge et al. 2005, Schifferstein et al. 2005). These strategies aim to create a strong emotional bond between the user and the product, thereby making the user less likely to dispose of the product. Several strategies to improve the immaterial values of a product have been documented, for instance: creating a product that pleasures use, has an aesthetic appeal, stimulates memories, and nostalgia, underlines self-expression creates enjoyment, or evokes sensory pleasure (Mugge et al. 2005, Normann 2004 Cooper 2010).

If the DLCP would be supporting users to make a transition into more sustainable consumption patterns, it must move beyond the rational domains of waste, recycling strategies, and include extended-product-life services, and more emotional domains to nurture a product's immaterial value to promote product longevity.
But what is the type of "data" in the DLCP that can promote product life and propone product obsolescence seen from the perspective of the user? We are looking for life prolonging DLCP data points, which will motivate and empower stakeholders to promote product lifetime.

### *Resisting product obsolescence*

The following section will use the framework of the circular design described by Den Hollander et Al. (2017) as a vehicle to structure our contribution to the DLCP data collection. Den Hollander et Al. (2017) described how designers and manufacturers can work strategically with design as a mean to develop products with a long use phase.

Products with a long-use phase have first been designed with high physical and emotional durability. Durability in the physical properties of a product has extensively been researched by e.g., Keoleian and Menery (1993), Bijen (2006), Vezzoli & Manzini (2008). Physical obsolescence and degradation can, for instance, be caused by wear, fatigue, creep, and corrosion and can, to a certain extent, be influenced by the design of the product and its components (Goel & Singh 1997). The DCLP will not directly be involved in the physical durability of products, however, the storytelling of a particularly high-quality material sourcing/ production technique or design ideology can serve as a strong narrative imprinted into the DLCP.

Secondly, products with high physical durability are often more expensive products, which becomes objective for illegal copies and theft. Low-quality copies thread the product and brand integrity, a DLCP can serve as a tool to authenticate original designs against fakes, this protects owners' investments, as validation in sale and insurance cases.

Products with high emotional durability have often been moving through several uses' cycles building up value. This domain is linked to science outside the traditional engineering domain and linked to the psychological and social relations between users and products. Long-term product attachment will take place when products are irreplaceable (Mugge et al., 2005). Grayson and Shulman (2000) extended this notion and suggested that the irreplaceable aspects of a product are the feelings and memories attached to them. To put these "soft" dimensions in perspective Chapman (2005) defines durability as, "just as much about desire, love, and attachment, as it is functionality." This is described as product attachment and researched by a series of authors (Page, 2014, Grayson and Shulman, 2000 Cooper (2000, Mugge et al. (2005), Schifferstein and Zwartkruis-Pelgrim (2008). Product attachment and emotional durability are influenced by many factors, some of which can be implanted and enhanced by designers, but many are difficult to control (Page 2014). If the DLCP can support users to form pleasurable memories, user customization, personalization, social affiliations, symbolic meaning, self-expression (Mugge 2007), identity expression, pleasurable use or memories of products as a reminder from past events (Ekman, 1992) the DLCP can serve to support user attachment and thereby advance products emotional durability.

A product-specific DLCP can support the emotional durability of products, by enabling stakeholders on different levels to shape the story of the product: This includes documentation of authenticity, as well as stories from different levels of the product life, including narratives about pre-production, such as stories about sustainable material sourcing, design ideologies, spectacular craftsmanship, authentic production, as well as personal use-stories and creative refurbishments. These are all stories that shape the product's digital patina and protect product integrity. Furthermore, can the DLCP promote a stronger relationship between the user, product, and manufacturer extending the collaboration into post-sales services such as take back-systems, rent, refurbishments, etc.

*Postpone product obsolescence.*

On the second level, Den Hollander et Al. (2017) described approaches for extended use. This means that manufacturers can provide products designed to be easy to **maintain, repair, or upgrade.**

Maintenance is conducted to retain a product's functional, cosmetic, or hygienic capacity. It is straightforward to imagine how the DCLP can assist customers with product-specific instructions and user manuals. Furthermore, can a localized DCLP also enable a link to the nearest maintenance services? This can include authorized OEM manufacturers as well as contact with local DIY activities such as repair shops or DIY communities.

Repair is conducted to restore a product's functional and aesthetic performance.

A DCLP can assist users with product-specific repair manuals and easy access to spare parts as well as contact local OEM repair hubs. A strong repair service can build product integrity and brand credibility, which would allow the user to push back the products into a new use phase or introduce it to the refurbished market. The DCLP would allow the secondhand user to see if previous repairs or refurbishments are

**Figure 1. Overview of dataset for product longevity and existing sub-models for the DCLP.**

conducted by authorized repair shops. This will protect the product- and brand integrity.

A product repair is traditionally related to a restoration of a product to its traditional state, however having stories embedded into the products, allow for new types of artistic repairs.

Products upgrades are related to the enhancement of a product´s functional and cosmetic condition. A product specific DCLP would allow manufacturers to communicate new variations and technological upgrades to the consumers. Consumers can track authorized or unauthorized updates, which also opens new types of creative entrepreneurs who see a gap in the refurbishment market, as seen in contemporary product hack communize.

### *Reversing product obsolescence*

The third level strategy manufacturers can take to postpone product obsolescence is to reverse product obsolescence by building products and services for recontextualizing and refurbishment of products.

**Recontextualizing** is a term for extended product use outside the context the product was designed to. (Den Hollander et al. 2017) The DCLP, have the potential to become an important tool to empower better after-sale services such as rent, takeback systems, and second-hand sale. Keeping track of product history, refurbishments and conditions can help users recontextualize different products. These services can be delivered as a service from the manufacturer, an authorized OEM, or by the user's initiative.

**Refurbishment** reset product obsolescence by taking products back for disassembly, testing, and replacing obsolete components on an industrial scale, often conducted by third-party manufacture. The products are considered eligible after testing to original performance specifications. The DCLP can support third-party manufacturers to manage authorized operations and track warranties on the product level.

*End of product life*
Is when a product is obsolete and will go to waste or recycling. The processes have been extensively described by Berger et. Al. (2022) and Adisorn et. Al. (2021). It is beyond the scope of this paper to unfold these domains; however, the authors are motivated by the challenge to postpone the end-of-product life date, because any recycling process will use a substantial amount of energy and often degrade material and product quality.

Mapping product longevity data
As the previous section reveals that extended product data has many potential stakeholders, all with their needs for data and data integrity. We have localized four levels of actors in the product longevity domain:

- Suppliers
- Manufacture
- Authorized OEM
- Users

Material suppliers will be the first level of input, it is essential that material sourcing data is correct and could link to data from the Materials Passport (EU 2021) or Resources Passport (EU1 2021). Secondly, the manufacturer is responsible for data about the production, material sourcing, and design, as well as authenticity and information about product customization or special limited editions. It is also the manufactures responsibility to provide systems for registering the owner of the products and provide manuals and access to spare parts and easy access to authorized workshops for repair and return service. The authorized OEMs can be production companies, auctioning houses, local repair workshops, sale services, etc., these certified interaction points, need to be able to read and write to the certificate in case of refurbishment/repair details. The third level is the product owner, who can update use stories or DIY refurbishments. Product owners would not have access to change any of the other levels due to data integrity. The static DPP has qualities related to static data such as Product identification, technical details, maintenance, and product manuals. Plociennik et.al. (2022) described how an Asset Administration Shell in the DCLP can be a vehicle for many different market-specific sub-models. They suggested basing the DCLP on the cross-industry standard ECLASS that provides master data for the classification description of products and services (ECLASS 2023). They recommend further including the German DIN 77005-1 standard defining dynamic lifecycle information which has been modeled as a “Lifecycle Status” sub-model, capture, legal, lifecycle documents, and material substances as well as hazards. Pioneering work in the field of computer science showcases how data structures can enable dynamic analysis of the Life Cycle Sustainability Assessment (Ghose et al. (2022). Building on this knowledge, we propose to further investigate and qualify data points from product longevity analysis. The authors suggest extending research in a new sub-model to the DCLP that include data points with the purpose to prolong the Product Longevity. We suggest that a DPP is adopted to satisfy the specific product categories' needs, meaning that a car battery manufacturer will have different needs than a furniture manufacturer. The PL is developed on the bases of the furniture industry but can be related to other industries. Some data points are already part of ECALLS and DIN 77005 – 1 standard. Figure 1 shows an overview of data points related to Product Longevity based on the review above. We propose to build a sub-model to the DCLP extending existing models including product ownership, storytelling, and important interaction points that support product owners' care, repair, and sell their products – This is a complimentary dataset that would fit the furniture market and other markets with potentially long-lasting products.

## Reflection
This paper introduced the concept of mapping Product Longevity data into a sub-model for DLCP. We argue that this dataset is essential if the Digital Product Passport, should realize its full potential; to be a tool to navigate consumption and build longer-lasting products due to product-life prolonging activities and interactions during the product lifetime. Furthermore, we argue that the DCLP can be a new tool to bring manufacturers, OEMs, and product owners closer together, realizing product longevity, due to closer connection and stronger relationships with new value propositions in the post-sale services, this is to be explored in future experiments. In the

project, we also found a great potential for tracking maintenance activities and authenticity control, because it protects customers' investment in better products. Also supporting the identification of product owners is relevant to insurance companies which also serves as a strengthen security of high-value and high-quality products.

This paper also brings light to a potential negative dynamic in the DPP, because the literature on product longevity shows that when products are reduced to their material level, they have a chance of destroying product integrity. Destroying product integrity, can harm product life and showcase counterproductive effects due to a potentially casual attitude to consumption.

If the goal of the DPP is to reduce consumption, we must produce and maintain long-lasting and enjoyable products. We need to build passports that motivate and empower stakeholders to promote product lifetime and postpone product obsolescence.

## Acknowledgments

This argument has been developed in discussions and DPP to the furniture industry. Thanks to sustainability manager Morten Lund from Fritz Hansen A/S and Jasper Overgaard and Christian Dyrman from Overgaard and Dyrman, and Anantha Peramuna from Nature Preserve for contributing to the development of these perspectives.

# Environmental Analysis of Multiple Food Packaging Formats in University Campus Food Services: Case Study at Toronto Metropolitan University

**William Ralph Snyder[(1)], Jonghun Park[(2)]**
1) Toronto Metropolitan University, Toronto, Canada
2) Toronto Metropolitan University, Toronto, Canada

**Keywords**: Food Packaging; Sustainability; Life Cycle Assessment.

**Abstract**: The purpose of this study is to assess the environmental impacts of the various food packaging systems offered at the Toronto Metropolitan University campus cafeterias. Three systems exist in this setting, single-use polypropylene (PP) containers, reusable polypropylene (PP) clamshells, and compostable bagasse clamshells. The goal is to understand which system has the most favourable impact regarding the TRACI 2.1 ten impact categories. The scope includes a cradle-to-grave life cycle assessment (LCA) consisting of raw material extraction and production, transportation, usage, and end-of-life disposal. This study investigates the environmental impact of each packaging system for 10,000 meals consumed by students. This research follows two ISO standards, 14044:2006, and 14040:2006. These standards involve defining the goal and scope, completing a life cycle inventory analysis (LCI), completing a life cycle impact assessment (LCIA), and interpreting the life cycle. LCI information is extracted using SimaPro v9.0. The study results reveal that the reusable PP clamshell has the most negligible environmental impact compared to the two other single-use packaging alternatives for all ten environmental impact categories. The single-use PP container has the most significant environmental impact due to its harmful material extraction, production processes, and end-of-life emissions. This research concludes that single-use food packaging options have a more significant environmental impact than reusable PP clamshells. Based on the research findings, installing energy and water-efficient dishwashers, sourcing the packaging locally, and reducing the loss rate of reusable PP clamshells could produce an even further favourable environmental impact for the reusable food packaging system.

## Introduction

Climate change and other environmental threats have become prevalent global issues. In response to these concerns, sustainability has become a prominent trend within the Packaging Industry. The Government of Canada revealed that food packaging waste is responsible for approximately one-third of all Canadian household waste, with only 20% being recovered for reuse and recycling (Government of Canada, 2020). Alongside this acknowledgement, Canada is working to successfully reduce plastic waste while contributing to reducing food waste (Government of Canada, 2020). In 2018, federal, provincial, and territorial governments began collaborating through the Canadian Council of Ministers of the Environment (CCME) to move towards implementing a circular economy for plastics in the pursuit of zero plastic waste (Government of Canada, 2020). The goal is to re-circulate all plastic types in the economy, negating entry into landfills and the environment. Determining and understanding the environmental impact of packaging systems is critical in maintaining animal, plant, and human life.

Recently there have been growing environmental concerns regarding the sustainability of consumer packaging. A movement within the ongoing sustainability trend is the implementation of reusable packaging. Studies have been conducted to provide research and insight into many facets of reusable packaging, such as developing closed-loop packaging networks (Accorsi et al., 2020), the behavioural science of reusable packaging (Greenwood et al., 2021), thermally controlled shipping containers (Goellner & Sparrow, 2014), and the regulatory framework that governs waste prevention (Tencati et al., 2016). The commonality between these topics is that a Business-to-Business (B2B) channel is being investigated and assessed. Overall, reusing packaging is not a new concept and has been used for B2B transactions for decades (i.e., Wood Pallets, Milkman model) (García-Durañona et al., 2016). However, implementing a reusable packaging system at a Business-to-Consumer (B2C) level is an emerging innovation within the food and beverage sector. Large corporations have begun exploring various avenues to reduce waste and promote the four R's, Reduce, Reuse, Recycle, and Renew (Johnson, 2019). When reduction is not a viable option, the next best choice is to reuse. Reuse systems are typically based on the consumer returning the empty packaging post-consumption, when it is collected, cleaned, and re-filled, creating no material waste. In this method, several complexities go overlooked, such as a heavy reliance on consumer participation, water and energy consumption, the durability of containers, and loss prevention.

Toronto Metropolitan University (TMU), located in Toronto, Ontario, Canada, is one of the many Canadian institutions that has begun implementing systems to reduce their environmental impact. The TMU cafeterias are responsible for feeding the 1,200 students living on campus (TMU Buildings, n.d.). The TMU Food Services has begun exploring ways to positively alter the current cafeteria's environmental impact. The exploration started with reusable to-go containers (Figure 1 (a)) being offered at the Hub Café and dining halls (Pitman Hall (PIT) and the International Learning Centre (ILC)) (TMU Waste, n.d.). When possible, the PIT and ILC dining halls now provide all students with this reusable to-go food container. During COVID-19, students who were in isolation protocol had the food delivered directly to them using standard single-use plastic (SUP) polypropylene (PP) food containers (Figure 1 (b)). Hungry students who require more food than one container's capacity are encouraged to put the additional food contents in a compostable bagasse clamshell (Figure 1 (c)). The system consists of a one-time purchase of the container; when the container is returned, the students receive a token; the token is then used during the subsequent visit in exchange for a new container (TMU Waste, n.d.).

**Figure 1. Images of the food packaging formats analyzed in this study. (a) Reusable polypropylene clamshell. (b) Single-use polypropylene container. (c) Compostable bagasse clamshell.**

The dirty containers are collected, cleaned, air-dried, and ready to be filled with food once again. Theoretically, this closed-loop system continues until the container is lost, broken, or worn out (after 300 cycles). Hypothetically, the reuse process reduces the production of PP clamshells and positively impacts the environment. This hypothesis must be verified through the quantitative data provided by a life cycle assessment (LCA).

The literature comparing the environmental impacts of reusable take-out containers to traditional single-use alternatives is scarce. Regarding the Canadian market, reusable packaging focused on B2C channels still requires quantitative research to objectively compare the environmental impacts of dining hall/cafeteria food packaging options.

This study aims to unveil the environmental impacts of reusable food packaging systems and compare the impacts against traditional single-use and compostable packaging alternatives. This research will provide the necessary data to determine the optimal packaging solution for reducing environmental impacts and aims to provide insight into understanding the areas of improvement.

## Materials and Methods

The LCA is a collection of input and output data encompassing unit processes within a product system (Kun-Mo & Atsushi, 2004). This research acted in accordance with two ISO standards, 14044:2006 and 14040:2006. These guidelines include defining the goal and scope, completing a life cycle inventory analysis (LCI), completing a life cycle impact assessment (LCIA), and interpreting the life cycle. SimaPro v9.0 was used to extract the most appropriate life cycle inventory information. A comparative analysis and the respective contribution analyses were conducted to interpret the LCA results.

### *Goal and Scope*

The goal of this study is to assess the environmental impacts of single-use (PP), reusable (PP), and compostable food packages

To understand which system has the most favourable impact within the Toronto Metropolitan Cafeteria setting. The scope includes a cradle-to-grave assessment consisting of raw material extraction and processing, transportation, usage, and end-of-life disposal. Geographically, the scope pertains to North America as the reusable clamshells are manufactured in Oregon, USA. The single-use (PP) and compostable systems are produced and distributed in Ontario, Canada. Each of the three packaging systems is used in Ontario, Canada, at TMU. This study will investigate the environmental impact of each packaging system for 10,000 meals.

### *Scenario Description*

For each of the three food packaging systems, the life cycles have been separated into four distinct stages:

1) Material extraction & production (Assembly),
2) Transportation,
3) Product use (Cleaning)
4) Waste scenario

The material production stage consists of polypropylene production processes for the reusable and single-use containers and bagasse sugar cane resin processes for the compostable clamshell. Furthermore, the formation processes for plastic and bagasse are considered, such as injection moulding. The transportation stage covers the transit of food containers from the manufacturing site to the TMU dining halls. The use phase relates to the clamshell's cleaning processes during its circulatory period. The end-of-life phase consists of the waste management scenarios, such as recycling, landfilling, and incineration. The system boundaries for these three food packaging systems are depicted below in Figures 2., 3., and 4.

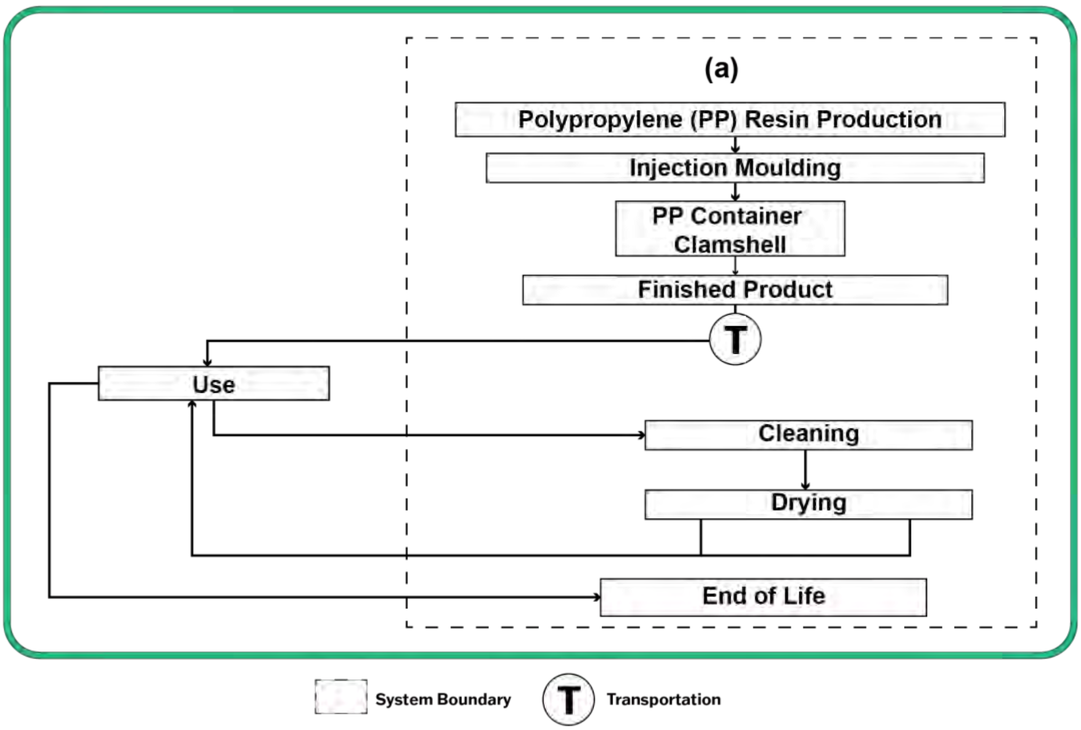

**Figure 2. Represents the system boundaries for the reusable polypropylene clamshell (a).**

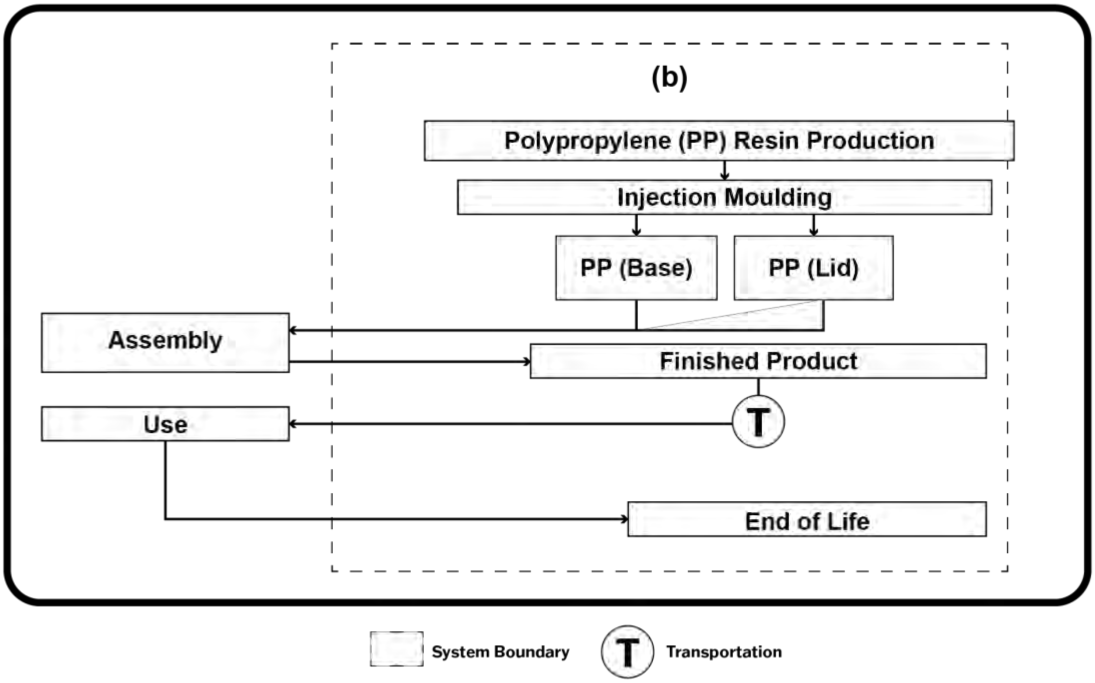

**Figure 3. Represents the system boundaries for the single-use polypropylene container (b).**

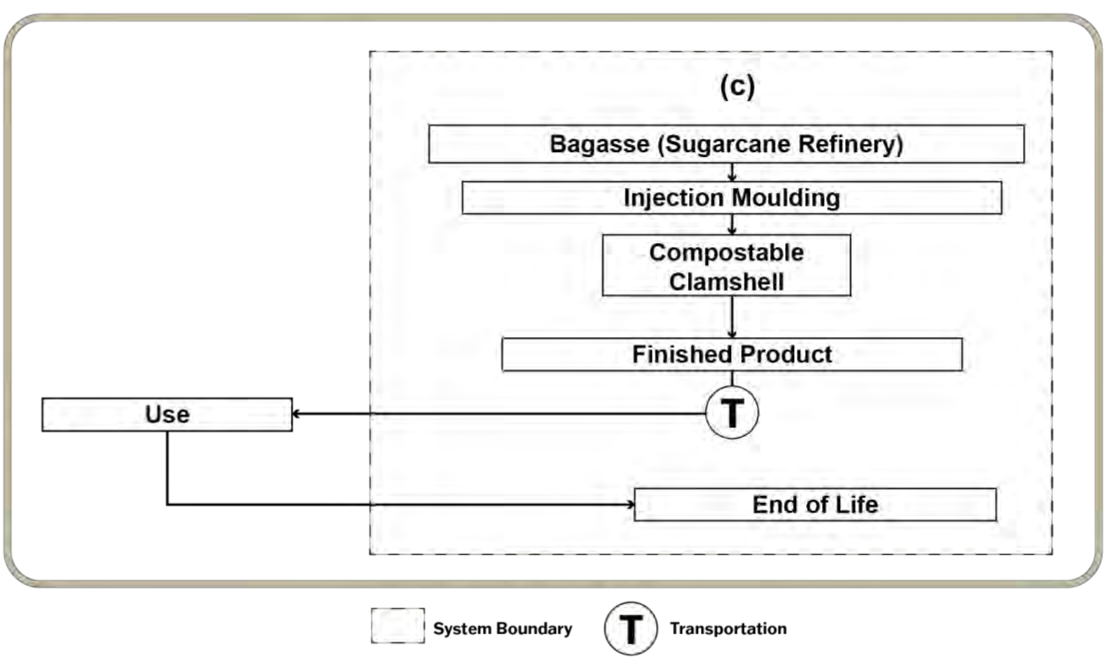

**Figure 4. Represents the system boundaries for the compostable bagasse clamshell (c).**

*Life Cycle Inventory Analysis*

Table 1 provides information about the life cycle inventory for modelling the production of each food packaging system based on the functional unit and corresponding weight of each packaging component. Of the available datasets embedded in SimaPro, US-EI Version 2.2 was sourced. The US-EI dataset represents the North American region and contains an expanded combination of USLCI and Ecoinvent datasets. US-EI consists of a wide assortment of processes and materials (LTS, 2021). Table 2 offers transportation information: the distances in tonne-kilometre (tkm), and the correlating dataset applied and the source of the dataset used. The single-use and compostable containers are both sourced from Ontario, Canada, while the reusable clamshells are sourced from Oregon, USA. For both transportation routes, the source of the data comes from USLCI. Table 3 presents the processes involved in cleaning the clamshells in-between uses. This stage consumes three key inputs: electricity, water, and detergent. Table 4 provides insight into the end-of-life processes for each packaging system and uses the US-EI dataset. Both PP systems use the packaging waste scenario, and the compostable system uses landfilling as its end-of-life scenario. The waste scenarios are based on Toronto's solid waste management practices.

| Material Extraction and Production | | | | | | |

**Table 4. Life cycle inventory for each packaging system's waste scenarios for 10,000 meals consumed.**

### *Life cycle impact analysis*

The life cycle impact analysis tool used to compare the three packaging systems was the Tool for the Reduction and Assessment of Chemical and other environmental Impacts (TRACI 2.1, US-Canada 2008). TRACI 2.1. is a midpoint oriented LCIA methodology developed by the U.S. Environmental Protection Agency. It includes ten environmental impact categories: ozone depletion, global warming, smog, acidification, eutrophication, carcinogenic, non-carcinogenic, respiratory effects, ecotoxicity, and fossil fuel depletion.

### *Limitations and Assumptions*

The system boundaries outlined for all three packaging systems created limitations. For example, this study neglected all secondary and tertiary packaging materials utilized in the shipping procedures. Because the reusable containers are only shipped once per year, and the compostable bagasse clamshell and single-use PP containers are shipped regularly, including this data would only further the environmental benefits of the reusable PP clamshell.

## Results and Discussion

This section reviews the cradle-to-grave LCA results for the functional unit of 10,000 meals of each packaging system. This study examined the ten impact categories within TRACI 2.1. The discussion will focus on the two most impactful categories; ecotoxicity and carcinogenics.

| Impact Category | Single-use Container (PP) | Compostable Clamshell (Bagasse) | Reusable Clamshell (PP) |
|---|---|---|---|
| Ecotoxicity | 1.39E+00 | 1.74E-01 | 3.14E-02 |
| Carcinogenics | 1.24E+00 | 4.88E-01 | 2.98E-02 |
| Non carcinogenics | 2.76E-01 | 9.17E-02 | 7.60E-03 |
| Fossil fuel depletion | 2.85E-01 | 5.12E-02 | 6.90E-03 |
| Eutrophication | 1.01E-01 | 5.62E-02 | 2.42E-03 |
| Global warming | 7.36E-02 | 3.84E-02 | 2.04E-03 |
| Acidification | 5.34E-02 | 2.78E-02 | 2.63E-03 |
| Smog | 4.22E-02 | 2.04E-02 | 3.46E-03 |
| Respiratory effects | 8.94E-03 | 6.14E-03 | 3.56E-04 |

**Table 5. Environmental impact of each food packaging system for each impact category.**

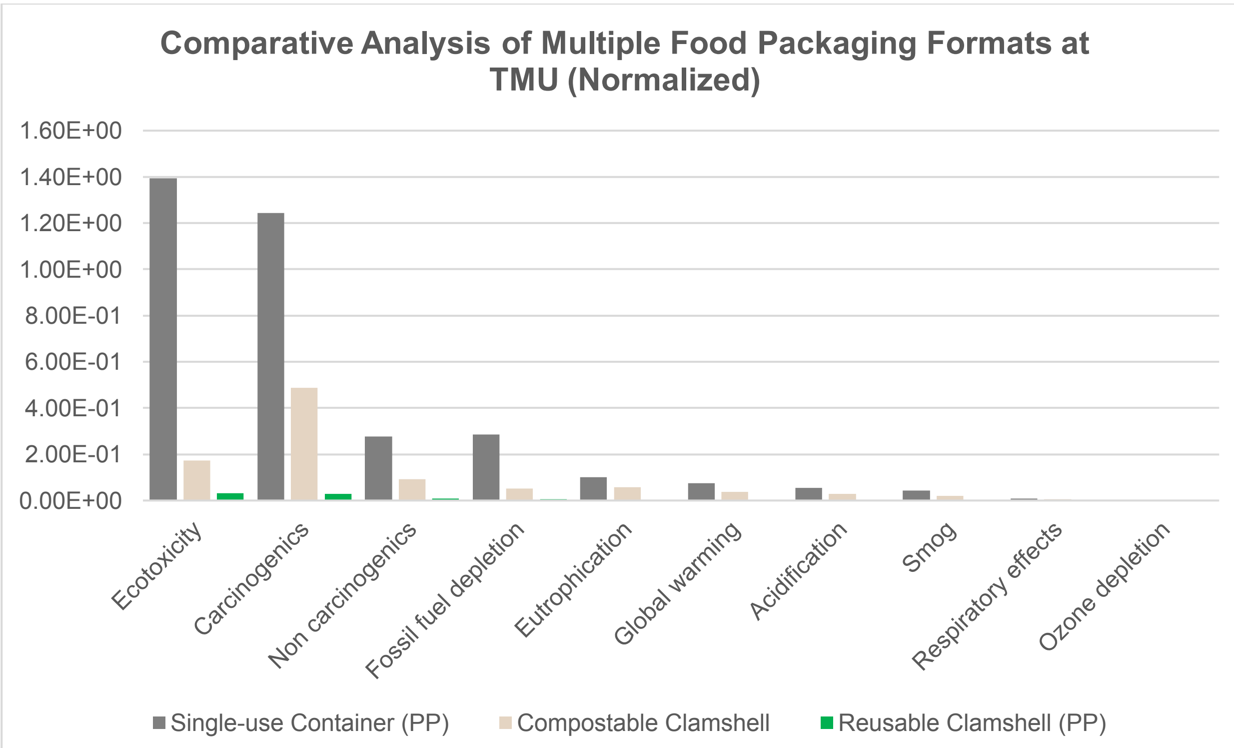

**Figure 5. Normalized comparative analysis of the TMU food packaging systems (reusable PP, single-use PP, compostable).**

### *Results of Comparative Analysis*

Table 5 provides numerical data for each impact category and each packaging system. Figure 5 depicts the comparative LCA of three packaging systems: compostable clamshell, reusable clamshell (PP), and single-use container (PP). Evidently, the single-use plastic (PP) container was the most environmentally impactful for every category. The compostable bagasse clamshell was the second most impactful across all ten impact categories. The reusable PP clamshell is the least environmentally impactful packaging system offered at TMU. Of the ten categories, ecotoxicity and carcinogenics experienced the highest levels of impact.

| Impact Category | Unit | Total | Material Extraction and Production | Transit | Packaging Waste |
|---|---|---|---|---|---|
| Ozone depletion | kg CFC-11 eq | 3.40E-04 | 3.39E-04 | 1.24E-10 | 4.63E-07 |

**Table 8. Contribution impacts for the reusable (PP) clamshell packaging system.**

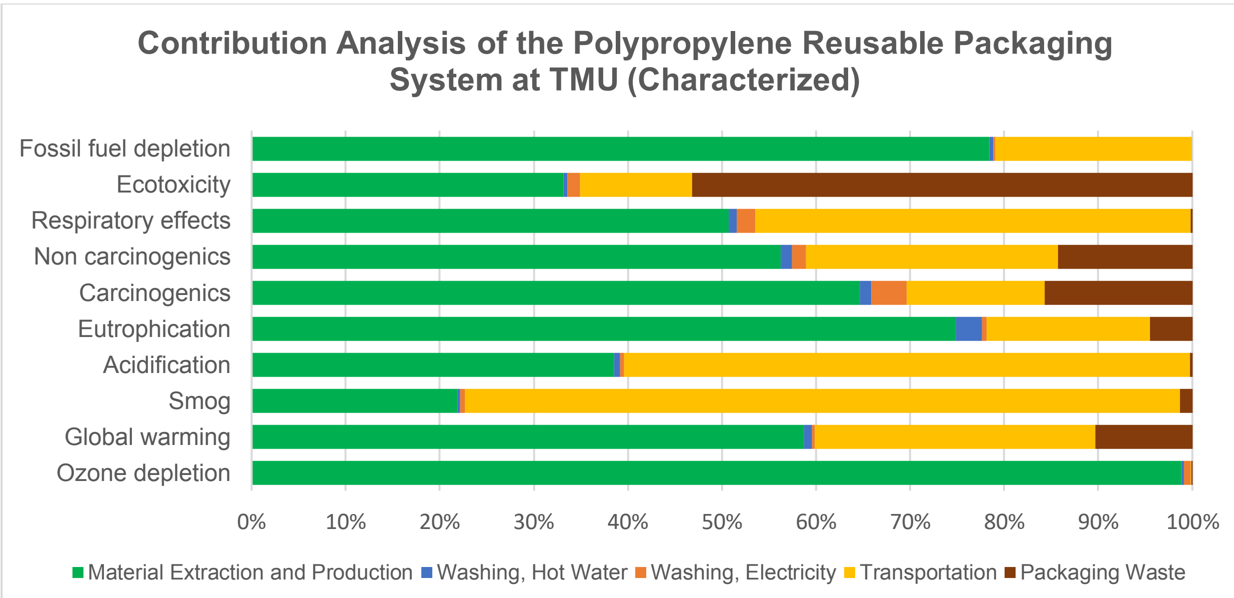

**Figure 8. Contribution analysis of the reusable (PP) clamshell TMU food packaging system.**

*Results of Contribution Analyses*

Table 6. provides the numerical data used to generate figure 6. Figure 6. displays the impact assessment of the PP single-use container for each of its relevant life cycle stages. Holistically, the most environmentally harmful process is the material extraction and production of the packaging system, followed by the impacts brought forth during the end-of-life scenario. Notably, the transportation process had a relatively negligible impact. This is primarily due to the local supply chain used to source the containers and the B2C environment of the campus food cafeterias at TMU. Regarding the two most impactful categories, ecotoxicity and carcinogenics, the contributing factors can be linked to the package's production and disposal operations. Specifically, the crude oil used during production alongside the harmful effects of incineration and landfilling (i.e., sulfidic tailings, tailings from hard coal milling, hard coal ash, etc).

Table 7. and Figure 7. provide valuable information on the process contribution impacts for the compostable bagasse clamshell. Similarly to the single-use PP container, the transportation phase correlates to insignificant impacts for nearly all ten categories for the same rationale. The stark contrast to the SUP option is made clear in the end-of-life phase. The bagasse end-of-life processing results in a negative numerical value for 70% of the categories. This can be attributed to the fact that the carbon dioxide that is produced during the end-of-life stage is offset by the carbon dioxide absorbed by new sugarcane crops in the field during photosynthesis (Mann, 2016). This factor is a significant reason for the compostable clamshell being less environmentally impactful than the SUP container. Carbon offsetting is prevalent in both the ecotoxicity and carcinogenics categories, reducing the overall impacts brought forth during the harmful disposal processes (i.e., spoil from coal mining, hard coal ash, tailings, incineration residue, uranium tailings, municipal solid waste).

Figure 8. breaks down the process impacts for the reusable PP clamshell during its lifecycle. The

correlating numerical data can be found in Table 8. Evidently, the material extraction and production, long-haul transportation, and end-of-life processes are responsible for a majority of the overall impacts. The stacked bar graph indicates the minimal effects caused by the washing process (water, detergent, and electricity). Due to the long-haul transportation required for sourcing the packaging, the smog, acidification, and respiratory effects are severe.

Regarding the most consequential categories, the ecotoxicity and carcinogenic effects are primarily due to the crude oil used during the PP clamshell production and the disposal factors. The reusable PP clamshell is the least impactful packaging system for all ten of TRACI's impact categories. Additionally, the current return rate for the containers is only 40% at the Toronto Metropolitan cafeterias, meaning there are opportunities to adjust the system to create an even more favourable impact.

This study's results align with similar research conducted at UC Berkeley (Harnoto, 2013). Harnoto's study concluded that Cal Dining should use reusable clamshells over compostable clamshells (Harnoto, 2013). Similarly, this study provides evidence that TMU cafeterias should continue utilizing the reusable PP clamshell as it has the most negligible environmental impact of the three packaging systems discussed. The continued successful implementation of reusable food containers at a university campus should be noted.

## Conclusions

This study analyzed and compared the environmental footprint of dining hall/cafeteria food packaging options TMU. This research concludes that single-use food packaging options have more of an environmental impact than reusable clamshells.

Traditionally, B2C reusable packaging systems are deemed more environmentally impactful due to the trip distance and the additional transportation for instances where the cleaning process is executed from a different location than the consumption. University food services do not require this added transportation and can be one example in which a reusable food packaging system is successful in reducing environmental impacts. Industrial institutions such as primary, secondary, and post-secondary schools can gain insight from the findings of this research.

Furthermore, opportunities to improve the current cleaning and return rates could lead to an even more favourable environmental impact across the ten impact categories discussed. A continuation of research could utilize a sensitivity analysis to determine the break-even points. This study would reveal the lowest return rate at which the reusable PP clamshell is still favourable.

Recommendations to the practitioners based on the research findings are as follows: installing more energy and water-efficient dishwashers, sourcing the reusable packaging from a more local manufacturer, and reducing the loss rate of reusable PP clamshells. Executing these three recommendations could further reduce the environmental impacts of the clamshell.

## Acknowledgements

We would like to acknowledge the support the TMU Residence Food Services Manager, Malcolm Alphonso, and his team provided throughout this project.

## Funding

This research was funded by the Natural Sciences and Engineering Research Council of Canada (NSERC), grant number RGPIN- 2019-06386; DGECR-2019-00339.

# Consumers' repair practices and acquisition of new and used products identify the dynamics of resource flows in a society

**Michael Soegaard Joergensen[(a)], Alexander Lindeburg[(a)], Arne Remmen[(a)], Jens Dorland[(a)]**
a) Department of Planning, Aalborg University, Copenhagen, Denmark

**Keywords**: Product lifetime; Product repair; Product re-use; Product attachment.

**Abstract**: In order to collect knowledge about Danish citizens' practices with purchase of new versus used products, and repair needs and experiences, a survey was carried out October 2020 in the Capital Region of Denmark among a representative sample of 1005 citizens based on an electronic questionnaire with a focus on citizens' experiences 2019-2020 with the repair and reuse of electrical and electronic products, clothing and footwear, and furniture. The main reasons across the three product types for buying a new product instead of a used product is a wish to get the newest model of product and not believing a used product will have a long lifetime. The main reason for buying a used product is a lower price comparing to buying a new product. For footwear, sport clothes and beds, the main reason for not buying a used product is reluctance buying used products that is used close to the body. A lower cost for repair compared to buying a new product is the reason for having an electronic product repaired. For some types of clothes and furniture attachment to the product is an important reason for having such products repaired. The two main reasons for not having a not-functioning product repaired is a higher price for repair compared to buying a new product or product repair not being possible. Thus, prevention of waste is not the main reason for having a product repaired but it plays a role for some citizens. Lower repair costs and the ability to disassemble products could increase the number of repairs of electronic products. Re-design for disassembly seems especially to be able to increase the number of repairs of kitchen equipment like toasters, water kettles, etc.

## Introduction

In the current system of production and consumption, products are disposed by the citizens even though the products might still be functioning or have defects that could be repaired. This phenomenon can be related to technical, material, or functional obsolescence (Jaeger-Erben et al., 2021).

Life cycle assessments show the importance of prolongation of product life time through repair and reuse compared to recycling of products.

Analyzes of consumers' repair needs and experiences and their purchase of new versus used products is therefore important as part of analyzes of a society's characteristics as a linear and/or a circular economy. By including different product groups in a survey, similarities and differences among product groups can be identified and contribute with knowledge about the dynamics of resource flows in a society.

In a Danish project about waste and resource flows in the Capital Region of Denmark, a survey was carried among a representative sample of 1005 citizens based on an electronic questionnaire with a focus on the citizens' experiences with the repair and reuse of electrical and electronic products, clothing and footwear, and furniture (Jørgensen 2021).

## Theoretical background

The developed survey is based on a social practice approach, which "tends to emphasize the way individuals embrace and stabilize existing practices" (Halkier et al., 2011). This perspective is relevant "for studying stability in practices but also for gaining insight into how social change occurs." (Halkier et al., 2011). This theoretical background implies that a person's practice is seen as shaped by interactions between the person's values, the involved technologies and the person's competences.

## Methodology

The questionnaire is made up of a number of standard demographic questions about the gender, age, education, household income and geographical "belonging" of the anonymized respondents in the form of postcode and municipality respectively.

The product-specific part of the survey is made up of three parts with a focus on electrical and electronic products, clothing and footwear, and furniture. For each of the three product groups, questions are asked regarding 6-8 specific product types with regard to the practices of the respondent's household during the period as well as the background of these practices:

- Whether a product has been acquired
- Whether the product was new or used - and the background for this choice, where one or more reasons are chosen from a number of possible reasons and a category "Other")
- Whether there has been a need to have such a product repaired
- The age of the product when the need for repair arose
- Whether the product was repaired, expected to be repaired or not being repaired – and the background for this, chosen from a number of possible reasons and a category "Other")
- Who repaired the product

The specific product groups within each of the overall product types in the survey were:

- Electrical and electronic products: Mobile phone, computers, TV set, refrigerator and freezer, washing machine and tumble dryer, dish washer, kitchen equipment, and tools.
- Clothes and footwear: Coats and jackets, sweaters and cardigans etc., pants, dresses and skirts etc., shirts, sportswear and swimwear etc., and shoes and boots.
- Furniture: Sofa and armchair etc., cabinet and chest of drawers etc., shelves and racks, dining table and dining chairs etc., office desk and office chair etc., and bed.

Since the survey asked about the practices of the whole household responding to the questionnaire and not the practice of specific household members, it has not been possible to analyze how gender and age influence the role of used products and the repair needs and experiences.

## Results

### *Acquisition of new versus used products*

The product group most frequently acquired is clothing, followed by two groups of electronic products - mobile phones and kitchen equipment. The frequency of acquisition is lowest for white goods, and desks and office chairs. Acquisition covers both purchased products and products, which the respondents received as a gift or a donation.

The product group where used products play the biggest role (i.e. where the share of used out of the share who bought a new or used product) is furniture with almost 45% of the acquired dining tables being used (with the lowest reuse rate for furniture seen for beds (around 25%)).

The lowest reuse percentages within clothes and electrical and electron products are seen for kitchen equipment, sportswear, swimwear etc. as well as shoes and boots, where the most frequent reason for buying a new product is that the citizen does not want to acquire a product, which others have used.

### *Repair needs and repair experiences*

Across product groups, office furniture is oldest when the need for repair arises, with only 18% of the need for repair occurring on products that are less than 5 years old. Within electrical and electronic products, refrigerators and freezers are the oldest when the need for repair arises with 26% of the repair needs on products less than 5 years old. Within clothing, the need for repair appears in most cases before the product is 5 years old, with shirts as the group of clothing that is the youngest with approximately 60% of the repair needs before the product is 5 years old.

The products that are youngest when a need for repair occurs are mobile phones with 32% of the repair needs occurring when the phone is less than 2 years old, and 88% occurring on mobile phones less than 5 years old. Similarly, footwear has a high frequency of repair needs for footwear on products less than 5 years old (78%).

For furniture, shelves and racks are the product group that has the lowest product age when a need for repair occurs, with 48% of repair needs on products that are less than 5 years old.

The problem with short product lifetime is biggest for mobile phones and footwear, as the repair needs for the two product groups have the highest frequency with 18% and 27% of the households experiencing a need for these repairs each year, respectively, while the corresponding figure is only 2% for shelves.

The problem with the lifetime of mobile phones and footwear is worsened by the fact that only 38% of the “broken” footwear is repaired (or expected to be repaired) and only 45% of the “broken” mobile phones are repaired (or expected to be repaired). Furthermore, a high frequency of repair needs and a high percentage abandoned repairs is a problem within electrical kitchen equipment.

It is mostly economic considerations about the costs of repair compared to the acquisition of a new product that most often determine whether a consumer decides to have product repaired. If it is cheaper to have a product repaired than to acquire another product (new or used), the product is repaired and otherwise it is discarded. However, for some groups of clothing and furniture, attachment to the product is the most frequent reason why a product has been repaired. Environmental considerations play a relatively small role, but for some groups of electronics and for beds, the desire not to create waste by disposing of a product is given as the second most frequent reason why a product has been or will be repaired.

### *Who is doing the repairs?*

For a number of product groups, it is the household itself that most frequently has repaired the product. For some groups of electronic products, the repairs were carried out through a retailer within the warranty period and at a repair company that the citizen himself has contacted also play a significant role and are indicated as the most frequent or second most frequent actor who has repaired. The same is seen for sofas and armchairs and for footwear. The only product group where repair cafes play a relatively large role as an repair actor is mobile phones, where such cafes are listed as the second most frequent repair actor. However, there might be a misunderstanding behind these answers. “Repair café” might be understood a mobile repair shop.

## Conclusions

The main reasons across the three product types for buying a new product instead of a used product is a wish to get the newest model of product and not believing a used product will have a long lifetime. The main reason for buying a used product is a lower price comparing to buying a new product. For footwear, sport clothes and beds, the main reason for not buying a used product is reluctance buying used products that is used close to the body. A lower cost for repair compared to buying a new product is the reason for having an electronic product repaired. For some types of clothes and furniture attachment to the product is an important reason for having such products repaired. The two main reasons for not having a not-functioning product repaired is a higher price for repair compared to buying a new product or product repair not being possible. Thus, prevention of waste is not the main reason for having a product repaired but it plays a role for some citizens.

Lower repair costs and the ability of products being disassembled could increase the number of repairs of electronic products. Within electronic products, re-design for disassembly might especially be able to increase the number of repairs of kitchen equipment like toasters, water kettles, etc. because the main reason for not having a not-functioning product repaired was that the product could not be repaired.

If manufacturers and retailers would agree to lower the repair costs after end of the warranty period, more products would be repaired and the manufacturers would get valuable information about vulnerable product components, need for more detailed user guidance, etc.

A warranty period for used products would probably increase the percentage of reused products being acquired. For mobile phones, backwards compatibility of new software would probably increase the product lifetime of these products.

## Future perspectives

If the survey was carried out as a nationwide annual survey every year, it could contribute with significant knowledge to national development and evaluation of strategies and plans within climate and circular economy. Researchers, national and local authorities, retailers, manufacturers as well as consumer and environmental organizations would be able to follow changes in the social practices of households and assess the effect of various efforts such as the introduction of differentiated waste fees, extended producer responsibility, cheaper repair options, new business models, establishment of more civil society repair cafes etc.

Analyses of similarities and differences among the region's various municipalities and neither the role of education and household income has not yet been carried out. These analyzes can enable the more specific development of local and national strategies for repair and the parts economy, including the need for focus on social justice.

## Acknowledgments

The survey and the analyzes of the data from were funded by The Capital Region of Denmark and Department of Planning, Aalborg University. The questionnaire was developed in cooperation with other members of the project group on "Waste and resources across the Capital Region of Denmark" in collaboration with the survey company Norstat.

# The Never-ending LCD Story: Transitioning the Electronics Industry in Ireland to a More Circular Economy

**Pratik Sondogar [a], Sinéad Mitchell[a,b]**
a) University of Galway; J.E. Cairnes School of Business and Economics; School of Engineering; Ryan Institute, Galway, Ireland
b) I-Form, the SFI Research Centre for Advanced Manufacturing, UCD, Dublin, Ireland

**Keywords**: Circular Economy; Critical Raw Materials; Electronics; Reverse Logistics; e-waste.

**Abstract**: The proliferation of short-lived electronic devices is resulting in mounting levels of e-waste worldwide. Increasingly, these products have LCD screens, from simple fitness trackers to kitchen gadgets and toys. Some raw materials used are Critical Raw Materials (CRMs) and of high importance to the EU economy. There are high risks associated with their supply and disposal, so need to be extracted safely. The Circular Economy (CE) is a sustainable solution and a financial strategy that facilitates the transformation of the existing linear system. Dismantling LCDs is labour intensive but there are also opportunities to reduce logistics cost in their second life, and an efficient process for the extraction of CRM is needed. This study investigated how companies in Ireland plan to comply with relevant EU directives related to this problem and find potential solutions to the barriers currently faced by the electronics industry, particularly companies that cater to LCD waste management. The study concluded that the key barriers faced were dependence on manual labour, lack of awareness about the EcoLabel initiative, lack of local processes within Ireland, and lack of a cost-effective solution for recycling. Some of the key recommendations to overcome these barriers are to increase awareness, foster collaboration and dialogue across the supply chain, and to allow customers play a bigger role in the CE of IT devices.

## Introduction

Consumer electronics has experienced exponential growth in the 20 years to satisfy our ever-increasing appetite for the latest smart gadget. Increasingly, even the smallest devices have LCDs (which have several applications e.g. PC monitors, laptops, tablet PCs, mobile phones, TVs, medical devices, smart watches, Fitbits etc.). While improving our lives in many ways, this has also lead to mounting levels of e-waste resulting in detrimental environmental impacts (Baldé, Wang, Kuehr, & Huisman, 2015). E-waste is a complex waste stream with various components involved such as metals, plastics and rare earth elements. Disposal poses various challenges. Some raw materials found in LCDs are listed as Critical Raw Materials (CRM) in the EU and now need to be extracted from e-waste (European Commission, 2017) (Coughlan, Fitzpatrick, & McMahon, 2018).

This research examines how the electronics industry in Ireland can adopt a more Circular Economy (CE), and investigates the barriers to implementation of CE practices there.

## Background

The concept of the CE stems from the limitations of linear production models and reconciling our current levels of production and consumption (Bradley, Jawahir, Badurdeen, & Rouch, 2018). CE encompasses various tasks that reduce, reuse or recycle resources in the value chain through better design, remanufacturing, refurbishment, repair and repurposing (Blomsma & Brennan, 2017) (Naustdalslid, 2014). Reuse and product life extension is often an optimum EoL strategy for electronics to balance the embedded energy from manufacturing (Williams, et al., 2008) (Babbitt, Kahhat, Williams, & Babbitt, 2009). A recent surge for good quality reused and refurbished electronics is evident by new recent successful marketplaces like Swappie, Music Magpie, Refurbed and others (Baldé, Wang, Kuehr, & Huisman, 2015). However, much of direct reuse is contingent on hardware relevancy, product demand, condition of components both cosmetically and functionally (Williams, et al., 2008) (Babbitt, Kahhat, Williams, & Babbitt, 2009) (Cooper & Gutowski, 2015). Repurposing or adaptive reuse is salvaging and extending use of individual components when the whole product fails to function as a unit (Cooper & Gutowski, 2015). Repurposing e-waste has been a design strategy in some companies, such as using LCDs as TVs (Kwak, Behdad, Zhao, Kim, & Thurst, 2011) and smartphones as parking metres (Zink, Maker, Geyer, & Amirtharajah, 2014). These avenues for repurposing view the product as an assembly of various useful parts rather than just as a singular product (Long, 2016).

E-waste often comprises useful raw materials that are not being used optimally and are not being recycled. The EU has deemed some of these as Critical Raw Materials (CRM) owing to their rising demand, economic value and a possible interruption in their supply in the future future (European Commission, 2014) (United Nations Environment Programme (UNEP), 2017).
Smartphones contribute significantly to the growing levels of e-waste containing and hazardous rare materials valuable metals such as gold platinum, cobalt, palladium and silver (ngondo, 2011). Materials, such as indium, which is present in LCDs, has been deemed a CRM (European Commission, 2014; United Nations Environment Programme (UNEP), 2017). Estimates put recovery of metals in smartphones at a value of €746 million (Cucchiella, D'Adamo, Lenny Koh, & Ros, 2015). If devices were designed to be disassembled, recovery of CRMs could be increased (Chancerel, Bolland, & Rotter, 2010). Pre-processing Waste and Electronic and Electrical Equipment (WEEE) can extract a significant amount of aluminium and iron without loss of precious metals. However, dismantling is expensive, particularly for medium and large EEE products and for products enriched in important materials (Willems, Dewulf, & Duflou, 2006). Consumer compliance plays a major role in the success of CE, with smartphone collection rates as low as 20% in some regions (Sugiyama, Honma, & Mishima, 2016).

The process by which used products are restored to a "like-new" condition functionally is known as re-manufacturing (Zlamparet, et al., 2017). Laptop manufacturers have incorporated a successful model from dismantling returned laptops - remanufacturing and amalgamating new and old components to OEM product specifications (Den Hollander, Bakker, & Hultink, 2017). Refurbishment is when products are tested for defects, repaired, resulting in restoring a device to working condition and sold with a refurbished tag (M, 2008). Reuse has been incorporated in various more business models in the last decade (Kissling, et al., 2012), and is on the increase.

CE can be considered a step towards sustainable development (Kirchherr, Reike , & Hekkert, 2017). All actors in the value chain from linear to circular strategies at all levels note that reuse also benefits society by creating jobs and empowering low income earners (O'Connell, Hickey, & Fitzpatrick, 2012). To achieve a CE, companies should focus on extending product life, promoting reuse, and minimising waste of relevant materials through recycling (Stahel, 2016). However, there is often a lack of clarity on how one can implement CE practices at a practical and micro level (Urbinati, Chiaroni, & Chiesa, 2017; Elia, Gnoni, & Tornese, 2017). Various implementation frameworks have been proposed, like Elia et al.'s (2017) four-level framework and Su et al's (2013) model. The positive change in the business-environment relationship can act as an incentive in adopting a CE paradigm (Brown & Stone, 2007; Ghisellini,, Cialani, & Ulgiati, 2013). A organisation's culture and perception is the main enabler for successful implementation of CE (Rizos, et al., 2016).

The design of a product should promote recyclability and optimise EoL treatment. This can be achieved through policies that promote better design principles (Mathieux, Froelich, & Moszkowicz, 2008), along with practices that enhance waste collection and recycling (Bouvier & Wagner, 2011). Policies that advocate resource efficacy focus on end-of-pipe waste treatment such as the Waste Directive (European Parliment, 2008) and the WEEE Directive (European Comission, 2019), The EcoDesign Directive (European Comission, 2022) and the Ecolabel Regulation (European Parliment, 2017) are policies promote that cleaner production. Both have emphasised dismantlability as a key attribute for product recyclability, which can encompass minimisation of materials and the time to disassemble. Dalhammar (2016) advises the establishment of programs that explore the more cost-effective recycling methods especially critical metal recycling, new techniques, better prototypes and well laid out product specifications that incorporate new standards. Producers could be pushed to adhere to some levels of performance (for e.g. as per the EcoDesign policy for energy-related goods) before releasing the goods for sale, to remove goods too difficult to disassemble. Producers could also be encouraged to design with higher standards and environmental performance levels.

Disassembly of LCDs is a critical step for CE (Chen, 2006). When LCD devices are brought back from the customer, retailer, or waste management facility (reverse logistics), they can be disassembled manually or through automation. Manual disassembly (e.g. on a 17 inch monitor) can take anything from 6.5 minutes (including removal of PCBs and LCD) (Kim & Kim, 2019) to 25mins (Salhofer, Spitzbart, & Maurer, 2011). While automation can reduce this significantly to one minute, but this results in outputs that can only be shredded and not fully recovered (Kim & Kim, 2019) or retaining the components and associated embodied energy. Revenue generated from materials obtained may not cover the cost of operation, However, some components can result in economic gain (Salhofer, Spitzbart, & Maurer, 2011).

Glass & Indium Tin Oxide (ITO) can be separated and recovered from LCD. ITO is a transparent conducting material used in most of touchscreens worldwide (Dang, Wantz, Hirsch, & Wuest, 2017). ITO is significantly important with a substitution index of 0.97/0.94 and a valuable CRM in high demand (European Commission, 2017). LCDs are a potentially a better source of raw material indium than other waste (e.g.batteries and automobiles) (Ciacci, Werner, Vassura, & Passarini, 2018). The separated glass can be used in construction to produce cement bricks, and industrial glass wool.

## Research Methodology

This study set out to understand (RQ1) how companies in Ireland deal with CE for e-Waste, and (RQ2) what solutions could help to overcome barriers to implementation.

A qualitative research method (semi-structured interview) was chosen to foster understanding of phenomena in a socio-technical context (Myers, 2019) and to allow a degree of freedom to explore responses in more depth (Collis & Hussey, 2013). The questions were based on Gorden’s funnel approach (1975) (1975) and consisted of six sections as shown in Figure 1.

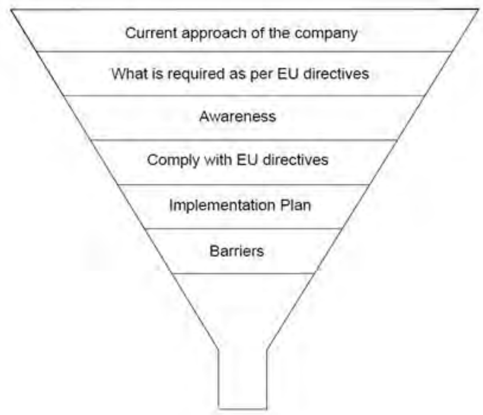

**Figure 1. Funnel Approach taken for semi-structured interview design in this study.**

Interviews were conducted online with three specialist Irish companies who are the dominant players in dealing with LCD waste streams.

## Results and Discussion

All the companies are following WEEE directives to remove harmful components from LCDs. One company has proprietary automated recycling technology, leading on processing e-waste generated from LCDs - the others are more active in the re-use and repair.

Most the companies were unaware of the EcoLabel, perhaps because it is not prevalent or prominent in Ireland compared with other EU countries.

All companies have some awareness of EU polices, e.g. indium being listed as CRM. However, when questioned further, two were unaware of appropriate methods for removal of CRMs found in LCD, and lacked knowledge of economic the value of indium.

Manual labour is extensively used for disassembly, repair, re-use and recycling of IT devices which maintains valuable components. Automation can increase the speed but damage is caused to the adjacent components where the possibility of re-use is lost, aligning with other studies (Chancerel, Bolland, &

Rotter, 2010). If a design promotes dismantling and sorting of products based on their material composition, then the amount of rare and critical metals generated increased. Only one company was aware that ITO is present in LCDs.

The barriers to recycling and refurbishment were not surprising, with one major issue being the reliance on costly manual labour in LCD extraction (to disassemble, test, and replace LCDs) and EoL LCD processing - the relatively low volume has prevented investment in developing automated solutions.

Another issue is the difficulty in returning recovered components and material due to the location of original manufacturers (mainly in Asia). Companies are looking for a cost-effective solution and are hoping for developments in alternative recycling technology.

The third barrier is the cost of the recycling compared to the value of material recovered. It can be difficult to justify the cost of recycling low volumes (for recyclers) despite recognising the need to recover the material and generate revenue. The activity is mainly driven by compliance to legislation.

The fourth barrier is the lack of LCD material recovery processing on the Island of Ireland, with only one operation existing. A lot more is happening on this issue globally, making it more economically viable elsewhere due to economies of scale (such as reusing plastics into filament for 3D printing, or granules for re-use, PCB recovery, component harvesting, etc.).

## Recommendations

This study has given six key areas where improvements could be made in managing used LCDs in Ireland.

Firstly, increasing awareness and use of the EU Eco Label could potentially provide a higher value to a company's service offering.

Secondly, providing support to help companies maintain economic value of recovered materials and components. This could involve supporting companies to find reuse, refurbishment, remanufacturing and recycling options on the Ireland of Ireland. Or alternatively providing safe, appropriate and affordable channels to move the materials where there is a demand outside the country.

Thirdly, supporting more collaboration in CE activities in Ireland. The interviewees showed openness to collaboration and promote the supports that have become available (e.g. (CirculEIRE)), as the EC strongly recommends close collaboration between companies to maximum material value retention, and reducing raw material production costs. For example, the ITO layer in LCDs could be recovered and processed by recyclers in a way that eliminates the need for manufacturers to pre-process it and directly use it for its second life application.

Fourthly, companies should be supported to reduce the high operational cost. The companies are aware this work is critical to maintain a stable supply chain. Supporting investment in automation for disassembly would help.

Fifthly, aligning companies with the EU EcoLabel to promote and provide the potential for consumers to play a key role in the disassembly of IT devices (if it was made easy for them to do so). This could displace some of the costly manual labour and should also allow consumers to have devices that are upgradable and repairable rather than replacing them. A knowledge portal for DIY how-to videos can be created which would allow consumers to pinpoint the problems in their devices themselves (similar to (FAIRPHONE, 2023)).

The sixth recommendation is conduct further research engaging with consumers perceptions, as they play a major role in making CE a success (Sugiyama, Honma, & Mishima, 2016). Undertaking more research and development in supply chains to improve efficiency is another potential area for further research.

## Conclusions

This research has reported on the awareness and activities of companies in Ireland working with LCD processing at EoL. As Ireland is a small country, there are few actors involved, but these companies have great awareness of the need to continue and improve LCD recovery and reuse activities. However, there are many barriers that need to be overcome, and would need government support due to the relatively low volumes of material, to keep these valuable companies viable, and to contribute to the difficult parts of achieving the CE, such as dealing with reverse logistics operations that have not been designed with ease of disassembly, refurbishment and recovery of components in mind.

# Write to Repair: Lessons learned from developing an EU reparability scoring system for product policy

**Spiliotopoulos, Christoforos; Alfieri, Felice**
European Commission, Joint Research Centre (JRC), Seville, Spain

**Keywords**: Reparability; Smartphones; Eco-design; Labelling; Product policy.

**Abstract**: Repair, as a strategy for product lifetime extension, is gaining prominence in EU policy debates and regulatory initiatives, as a means to achieve the Union objective of transitioning to a more circular economy. Such is the case also within two main pillars of product policy: the Ecodesign Directive (2009/125/EC) and the Energy Labelling Regulation ((EU) 2017/1369). At the same time, reparability scoring offers a useful assessment tool to generate information for the purpose of setting performance or informational requirements. The Joint Research Centre of the European Commission, in collaboration with the Directorate-General for Environment, carried out a project to develop a reparability scoring system for smartphones and tablets that aspires to constitute the first such system to be adopted in EU policy, specifically the Energy Labelling regulations for these product groups. This paper presents lessons learned from this project of building a reparability scoring system that is based on a combination of technical and service-related repair parameters, but also fit for regulatory purposes. The selection of relevant priority parts (components) and reparability parameters is described, as well as the decisions to consider but exclude others, on grounds of the ability and complexity to (a) set regulatory requirements on, (b) verify by market surveillance authorities and (c) aggregate and present in a meaningful way to inform consumer purchasing decisions. Looking forward, the paper finally discusses the extent to which the method can be reproducible and adjustable to other product groups, including consumer electronics more widely, other electrical appliances, and beyond, in the context of the Commission's proposal for Ecodesign for Sustainable Products Regulation (ESPR).

## Introduction

In support of a possible introduction of product reparability scoring in EU policy, the Joint Research Centre of the European Commission developed, in the period 2018-2019, a methodology for measuring the reparability of products also called reparability scoring system (hereinafter "general RSS") (Cordella et al, 2019).
This method built on the experience gained by the standardisation work of CEN-CENELEC-JTC10 during the development of the standard EN 45554:2020 (CEN-CENELEC, 2020) as well as the experience from other initiatives at Member State (e.g. France), research or voluntary level.
In March 2022, the Ecodesign and Energy Labelling Working Plan 2022-2024 (European Commission, 2022a) referred to the general methodology and announced that the Commission is exploring the potential of introducing it for relevant products, possibly as information on the energy label for specific products such as smartphones and tablets.

In parallel, the Commission published a legislative proposal on Empowering Consumers in the Green Transition (European Commission, 2022b) amending the Consumer Rights Directive, proposing to include in the information requirements before a consumer is bound to a sales contract, where applicable, the reparability score for the good.

## The RSS for smartphones and slate tablets

In December 2022, the Commission, in cooperation with the EU member states, decided to introduce an EU Energy Label for smartphones and tablets. For the first time, the Label will also feature a reparability index and manufacturers of smartphones and tablets must indicate by use of a score, with a scale of A-E, how easily their devices can be repaired. The Label is planned to be available on devices across the EU starting in 2025.
The authors of this paper were directly involved in the development of the method

(Spiliotopoulos et. al, 2022) and its inclusion in EU regulation. According to the principles defined in the general RSS, three steps were followed. The first step entails an identification of priority parts for the product category, in order to limit the reparability assessment to a reasonable amount of effort, based on concrete criteria, notably the failure rate and the functional relevance of the parts (higher rate and relevance meaning higher priority). Secondly, a set of parameters relevant to reparability are considered, and, again, the most important are selected for the subsequent assessment steps. Two distinct categories of parameters are considered, (a) design-related, referring to parameters which characterise the technical design of the product and affect its ability to be disassembled, and (b) service-related, which refer to provisions by the product manufacturer that deem the product reparable or not (such as disassembly information, or spare part availability). What follows is a scoring system for each parameter and, in the case of design-related parameters, also for each part. The transposition of the general method to the product specific applications is illustrated in Figure 1.

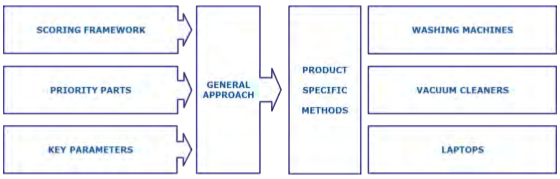

**Figure 1. The JRC RSS method from general to product-specific. © Cordella et al, 2019.**

Each step of the general RSS method was considered in the product-specific application, as well as for the purpose of accompanying ecodesign minimum requirements and display the result directly to consumers on an energy label. The following tables present the priority parts (Table 1) and reparability parameters (Table 2) selected (the latter vis-à-vis parameters previously identified in the general RSS method).

| Part covered with ecodesign requirements | Part selected for the smartphones and tablets RSS |
|---|---|
| Battery | X |
| Display assembly | X |
| Charger | |
| Back cover (/assembly) | X |
| Front-facing camera assembly | X |
| Rear-facing camera assembly | X |
| External audio connector(s) | |
| External charging ports | X |
| Mechanical button(s) | X |
| Microphone | X |
| Speaker(s) | X |
| Hinge assembly | X |
| Mechanical display folding mechanism | X |

**Table 1. Priority part selection.**

| General RSS 2019 | Parameter covered by ecodesign requirements | Smartphones and tablets RSS |
|---|---|---|
| Disassembly depth | (none) | Disassembly depth |
| Fasteners | removable | Fasteners (type) |
| Tools | commercially available | Tools (type) |
| Disassembly time | (none) | (via other proxies) |
| Diagnosis support and interfaces | Via repair info | (not selected) |
| Type and availability information | Professionals; comprehensive | Info (target group; cost) |
| Spare parts (target group, duration of availability, delivery time, price) | Professionals; Smartphone: 5 years Tablets: 6 years | Spare parts (target group) |
| Software/Firmware updates | Security: 5 years Functionality: 3 years | Software Updates |
| Safety, skills and working environment | Generalist; Workshop environment | (not selected) |
| Data transfer and deletion | Data user encryption | (not selected) |
| Password reset and factory settings restoration | Factory settings reset | (not selected) |
| Commercial guarantees | (none) | (not selected) |

**Table 2. Reparability parameters selection.**

The following sections describe the main lessons learnt and provide some first qualitative considerations for discussion on the extent to which the method can be replicable on (a) other energy-related products (ErP)[1], and (b) non-energy-related products.

## Lesson 1: Identification and prioritisation of parts

*Priority parts in a regulatory context*
The application of the RSS to the product groups of smartphones and slate tablets aimed at supporting a regulatory process of setting ecodesign requirements on those product groups. As such, the decisions taken in the parallel process provided the basis for the development of the scoring system, including the identification of priority parts. The ecodesign process foresees the provision of spares for certain product parts, as a fundamental parameter of reparability. The parts listed for spare availability are those selected as priority ones for the reparability score too, with the exception of the charger (considered an independent device) and the external audio connector (considered a technology phased out from most new devices placed on the market).
Nevertheless, the RSS may be implemented even in the absence of other regulatory requirements, with the use of two criteria:

- the functional importance of the part (i.e. the extent to which a part is necessary for the delivery of primary or secondary product functions). The rationale here is to avoid an unnecessarily complex process of assessing parts which offer minor usefulness rather than technical functionality (e.g. some aesthetic elements).
- the frequency of failure of a given part. The rationale is for a focus of the assessment on most probable repair scenarios. It could be the case that a part fails more frequently or earlier in the product lifetime than most other parts. For example, in portable electronics, batteries tend to have a shorter lifetime than the most other parts, as they are exposed to aging mechanisms due to the charge/discharge cycles.

Sources for this assessment for smartphones and slate tablets were drawn from existing reports, consumer surveys and repair databases[2] [3] [4], and were used to assign weights to each part. However, the same criteria can be used earlier in the methodological process, as exclusion criteria for priority part identification.

*Replicability for other product groups*
The methodology is considered highly-replicable for ErP generally. These constitute products with distinct components, and for which variable failure rates are observed. Having all product parts failing at the same time would imply a repetition of repair processes at a rate which would effectively resemble a replacement of the whole product. ErP are often designed with a certain degree of complexity, which makes their reparability assessment dependent on multiple key parameters, and therefore the use of a multi-parameter reparability score relevant. Lastly, the reparability parameters identified as relevant for smartphones are likely to be relevant for consumer electronics in general, and even more so those which are battery-powered and comprised of parts which deliver very similar functions and failure profiles (e.g. displays, batteries).
It is safe to assume that the RSS, and its implementation to smartphones, can be adjustable and replicable also for products which demonstrate similar characteristics to ErP, even though not categorised as such in EU product policy: products such as bicycles or e-scooters are also comprised of distinct components with variable failure rates and functionality importance. Therefore, the methodological step of priority part identification

[1] Directive 2009/125/EC (European Commission, 2009) defines 'Energy-related product' as: *"any good that has an impact on energy consumption during use which is placed on the market and/or put into service, and includes parts intended to be incorporated into energy-related products covered by this Directive which are placed on the market and/or put into service as individual parts for end-users and of which the environmental performance can be assessed independently"*

would still be very much relevant, and similarities could even be observed in terms of the actual parts that would be prior (e.g. batteries or displays when present). Products which present fundamental differences in design might require a higher level of adjustment: for instance, many textile-based products, such as garments, often consist of a low number of (or less distinct) parts.

## Lesson 2: Identification and prioritisation of reparability parameters

### *Selection of reparability parameters in a regulatory context*

Regarding the parameters relevant for reparability of smartphones and tablets, those identified in standard EN 45554 and the JRC RSS provided the basis, though adjustments were also deemed necessary, especially towards developing a system which is appropriate to be used for regulatory purposes rather than a purely technical assessment. To that end, the following criteria were considered:

- C1: relevance and ability to set regulatory requirements at EU level

As in the case of part prioritization, the first consideration was ensuring that the reparability score is aligned with the parallel ecodesign regulatory process, and also acts in a complementary manner. As such, the majority of parameters selected are already subject to minimum requirements under the proposed ecodesign regulation: Tools, Fasteners, Availability of spare parts, Availability of software updates and Availability of repair information. The scoring system would, thus, build upon those requirements and reward designs and services which facilitate repair further. Additionally, Disassembly Depth constitutes a technical parameter of high relevance for reparability while offering a quantitative and objective metric to express the effort and time needed for disassembly. Furthermore, as no specific minimum requirements were proposed in the ecodesign regulation, a high weighting factor was deployed to reflect the parameter's importance.

- C2: ability to verify by Market Surveillance Authorities (MSAs) and to implemented across EU

The verification of EU ecodesign and energy labelling requirements by MSAs ensures that requirements are respected on the market, and as such, the ability of a parameter to be verified by MSAs is paramount for the applicability of the reparability system. Therefore, parameters were selected also on the basis of their technical objectivity, measurability and applicability across EU member states. In the context of the EU single market, most design-related parameters (Disassembly Depth, Tools, Fasteners), as well as some service-related parameters which are strongly related to technical characteristics (Repair Information, Spare Part Availability) are more easy to verify across EU, due to product uniformity, as well as the static nature of the parameters over time. On the other hand, parameters related to the price of spare parts of the availability of OEM repair services, though relevant to reparability, were considered but not selected, due to their variability both across EU member states and across time. Considering that the repair score as part of the energy label would provide a non-dynamic assessment of reparability at the point and at the time of sale, parameters of such volatility may easily lead to consumer confusion or a reparability score, which, quickly after the product's sale, would not be reflecting the status of relevant repair services.

- C3: ability to aggregate and present in meaningful way

Another important factor considered in the analysis of reparability-related parameters is that of the ability of those parameters to form an aggregated score, which would sufficiently enable an improvement of products reparability on the market. This criterion is related not only to the type of parameters selected, but also the quantity of parameters considered. Specifically, as each parameter contributes to the overall score by means of a weighting factor, the use of too many parameters would mean that some or each of those parameters would have too low weighting factors to effectively contribute to the overall score and stimulate design or service changes towards higher reparability. It was considered that a weighting factor of at least 5%

would be needed for a parameter to meaningfully contribute.

Furthermore, some parameters are intrinsically difficult to consider in an aggregated manner, such as the consideration of parts which are free from part-pairing (i.e. inability to replace parts without OEM authorization).

*Replicability for other product groups*

Both the methodological step of parameter selection, and the parameters themselves would be relevant to various degrees for most ErP. Differences regarding how relevant each parameter for a product group are likely to be observed between products which can reasonably be repaired by consumers (e.g. consumer electronics, or small household appliances like vacuum cleaners), and products for which most repairs require the skill and equipment of a professional. For instance, for products relevant to consumer repair, design-related parameters might be of high relevance in creating the conditions for such repair; by contrast, products relevant for professional repair (e.g. large household appliances, like washing machines or boilers) may benefit more from a focus on service-related parameters, in order to ensure that professionals have the spare parts and information available to apply their skills on.
The applicability of the methodological step of parameter identification and weighting for non-ErP is similar to that of the identification of priority parts. Non-ErP which demonstrate similar characteristics to ErP would be more reparable with the availability of services and a more modular design. With the increasing presence of electronic components and software in products otherwise not considered ErP (e.g. e-textiles), means that disassembly and updates are critical towards ensuring the feasibility and completion of repairs.
Again, products with fundamental design differences to ErP would require a higher level of adjustment of the RSS.

## Conclusions
The development of reparability scoring systems demonstrates high potential in providing reliable information to consumers, rewarding repairable products and ultimately encouraging more modular design towards lifetime extension. This paper presented insights from developing a reparability scoring system for smartphones and tablets for the purpose of display on an EU-wide label. It constitutes a first step for a wider discussion on the extent to which such system can be replicated, with adaptations, for other product groups. Ensuring a harmonised way of addressing reparability, including via scoring systems built on the same principles, would not only increase policy-making efficiency, as product policy enters a new phase and wider scope with the Commission's proposal for an Ecodesign for Sustainable Products Regulation, but also its effectiveness via better consumer awareness, acceptance and familiarity when making product purchasing decisions.

# Access-based business model for washing machines: Evidence from consumer testing

**Radmila Štangová[a]**
a) Department of Business Management, Faculty of Economics and Administration, Masaryk University, Brno, Czech Republic

**Keywords**: Circular economy; Access-based business model; Consumer acceptance; Household appliances.

**Abstract**: The household appliances industry has been identified as one of the areas with a high potential to adopt a circular economy since appliances such as washing machines burden the environment throughout their whole lifecycle (Bressanelli et al., 2020). This paper focuses on (smart) product-service systems, recognized as a promising circular economy strategy. In 2022, Gorenje Group started to test an access-based business model for washing machines and tumble dryers on a group of consumers who agreed to take part in the test. In this access-based business model, the company rents professional long-lasting washing machines and tumble dryers to the final consumers, taking care of delivery, installations, possible repairs and take-back. The appliances are equipped with sensors and monitoring usage data, sending them to the IoT platform. The aim of this paper is to analyze consumer feedback from the testing phase of an access-based PSS business model for washing machines and tumble dryers. The feedback was collected through the means of semi-structured interviews with the testers from the Danish market. The interviews revolved around topics such as customers' perceptions of the benefits and disadvantages of the business model, sustainability, ownership and psychological ownership, connectivity and data collection. The added value of this study lies in the fact that the insights were collected from the consumers based on their experience with the business model, rather than just potential customers.

## Introduction

As explained by Bressanelli et al. (2020), household appliances such as washing machines or fridges burden the environment throughout their whole lifecycle, which is why this industry is considered one of the areas with a high potential for circular economy adoption. One of the promising circular economy strategies seems to be (smart) access-based product-service systems (Tunn et al., 2019). Product-service systems (PSS) consist of "*a mix of tangible products and intangible services designed and combined so that they jointly are capable of fulfilling final customer needs*" (Tukker and Tischner, 2006, p.1552). The focus is shifting to offering solutions fulfilling the needs of the consumers rather than selling products (Kjaer, et al., 2017). Access-based PSS allow consumers to access the products for a fee without the need to purchase them (Tunn et al., 2020). The digital era led to the development of smart PSS in which smart products and e-services are integrated into one solution (Valencia et al., 2015).

PSS have been recognized to have the potential to extend product lifetimes (Kjaer et al. 2019). Since the service provider keeps the ownership of the product, he has the incentive to make it durable (Lacy and Rutqvist, 2016), intensify its use, prolong its service life, reuse parts and make the products cost- and material-efficiently (Tukker, 2015). However, access-based PSS have not been widely adopted in consumer markets and remain a rather niche mode of consumption (Borg et al., 2020; Tunn et al., 2021), since consumers must adapt their traditional consumption patterns (Kim and Hwang, 2021).

Previous studies identified numerous drivers and barriers to engaging in access-based consumption. Among the drivers or benefits, the literature presents access to products consumers could not afford to buy (e.g. Bardhi and Eckhardt, 2012), flexibility (e.g. Gullstrand Edbring et al., 2016; Rousseau, 2020), the possibility to try a product before committing to buy it (e.g. Lawson et al., 2016), outsourcing of responsibility to the service provider (e.g.

Elzinga et al., 2020), convenience (e.g. Cherry and Pidgeon, 2018; Gullstrand Edbring et al., 2016), no need to spend money on repairs (e.g. Borg et al., 2020), reduction of anxiety thanks to the certitude that any problem would be dealt with (Cherry and Pidgeon, 2018), no need to make a high investment upfront (e.g. Gullstrand Edbring et al., 2016), predictable monthly costs (e.g. Rousseau, 2020), or environmental benefits (e.g. Borg et al., 2020; Rousseau, 2020).

On the other hand, consumers might be discouraged by ongoing payments (Borg et al., 2020), higher expected total costs (e.g. Rousseau, 2020), the fear of damaging the product and being held responsible (e.g. Cherry and Pidgeon, 2018; Lang, 2018), lack of accessibility (e.g. Hazée et al., 2017). A major barrier is a preference for ownership (e.g Borg, et al., 2020; Poppelaars, et al., 2018; Rousseau 2020; Tukker, 2015).

Giving up material ownership can be supported by developing feelings of psychological ownership (Fritze et al., 2020), which is "*the state in which individuals feel as though the target of ownership or a piece of that target is 'theirs'*" (Pierce et al., 2003, p.86). This could also be important in the context of product care, since without a sense of ownership, users might treat products less carefully (Bardhi and Eckhardt, 2012, In: Ploos van Amstel et al., 2022). The attitude towards ownership can, however, differ between product types (Cherry and Pidgeon, 2018) and it has been called for further research of psychological ownership in the context of household appliances rental (Rogers, 2021).

The "smart" aspect of the offering might entail additional challenges such as concerns about the security and privacy of the data collected by the devices (Naeini et al., 2017). According to the Consumers International and Internet Society (2019) survey, 63% of respondents found connected devices creepy in the way they collect data about people and their behaviour. Zimmermann et al. (2018) report that the concerns are mainly related to hacker attacks, burglary, data theft and data abuse. However, it was pointed out that consumer privacy preferences are context-dependent (Naeini et al., 2017).

This paper focuses on consumer experience with an access-based business model for washing machines and tumble dryers developed by Gorenje Group as part of the ReCiPSS Project[1]. Within this model, Gorenje Group rents washing machines and tumble dryers to the consumers while keeping ownership of the appliances and taking care of installation, delivery, repairs and take-back. The company is deploying smart long-lasting durable appliances designed for professional use[2]. These appliances are equipped with sensors able to monitor operational and usage data and send them to the IoT platform. Each machine is supposed to serve at least 3 lifecycles and be refurbished twice. In 2022, Gorenje Group started to test this business model on "testers" – chosen consumers who agreed to participate. The test has taken part in four European markets.

The aim of this paper is to collect and analyze consumer feedback from the testing phase of an access-based business model for washing machines and tumble dryers. For this aim, semi-structured interviews were conducted with 14 testers from the Danish market.

## Methods

For the purpose of the test, the testers received the appliances free of charge for the testing period of 18 months and in return, they accepted to provide feedback and participate in interviews, surveys and/or workshops. The testers from the Danish B2C market were mainly recruited via LinkedIn, a small portion was made up of company employees. For this research, only the testers not employed at Gorenje Group were asked to participate.

28 testers were contacted by email with the request to take part in the interview, out of which 14 agreed to participate. The data was collected through the means of semi-structured interviews realized through a video call. The interviews took place from 5/12/2022 to 14/12/2022. The interviews revolved around topics such as perceived benefits and disadvantages of the concept, ownership and psychological ownership, sustainability and sustainability-related information, connectivity, and usage data.

[1] See https://www.recipss.eu/

[2] Asko Professional brand

## Results

Most of the testers stated they would consider becoming a customer of this service in a real commercial setting. This chapter contains the main results organized into topics outlined in the Methods section. It should be pointed out that the main focus was on washing machines, however, tumble dryers were also part of the test, therefore some of the comments relate to both types of appliances.

### *Perceived benefits and disadvantages*

Most of the perceived benefits and disadvantages stated in the interviews were in line with those presented in the literature review in the Introduction. However, several new perspectives emerged in this context. As for the benefits, it was appreciated that the service provider is the company which also manufactures the machines. Similarly, the trust towards the service was high because the service provider was considered to be of high quality.

> *"I know the service is there, if anything fails, I know that the service at Asko[3] is really good."* (A13)

> *"Our machines have not been broken yet but I have the assumption it would be fixed very very fast because there would be the key resource to do it."* (A9)

> *"It´s the company who manufactures the machines who arranges the installation, this I like very much, especially for the professional machines."* (A10)

Among the disadvantages, one tester expressed a thought that at the end of the contract, he might conclude that he would have done equally well with just a regular washing machine and a dryer, meaning that the added value would be insufficient. It was also interesting how consumers' perceptions of convenience with regard to costs differ; while some testers appreciated the model for knowing what the costs are and that there would be no extra ones, another participant considered monthly payments as a disadvantage because of the need to think about having the financial resources every month.

### *Ownership and psychological ownership*

Most of the participants did not feel worried about the fact that the machines are not in their ownership, some stating they have never given it a thought. The main concern in this regard was related to being held responsible for potential damage. These participants also admitted they were treating the appliances a bit more carefully than they would treat their own, which can also contribute to prolonging lifetimes. This might have been partly influenced by the conditions of the contract[4]. An opposing view also emerged; one participant stated he felt less afraid of breaking something when the machine was not his own.

> *"Depends on the contract, if someday they come and say I didn't wash properly, and I would have to pay the full price – I would be afraid of this."* (A6)

> *"I actually like the idea of having so expensive machine that is not entirely my own. I think if it was my own, I would be a bit more careful. It gives me a bit more safety, I guess. But that also comes with the whole package – I know if it's broken, I have some kind of safety."* (A9)

However, in terms of product care, most participants agreed that they would treat the appliance equally whether it was rented or their own. It was appreciated that it is easy to take care of the appliance because it tells the user what to do.

The testers gave various reasons why they did not feel different about non-owning the appliances than they would feel about owning them. It was suggested to be caused by the fact that the appliances were in the user´s house, that the process of acquisition was similar to buying, and that the usage of the product was also the same. The feeling of psychological ownership was also supported by the freedom to use it as the user wants and needs.

Those who perceived some difference in the feeling of ownership towards these products suggested that it could be reinforced by getting the usage data to be able to optimize the use of

[3] The brand of the appliances

[4] User is responsible for the damage caused by not respecting instructions for use, intentional action or gross negligence. Users would not be held responsible for damages caused by normal wear and ageing.

the product, a good contract assuring the consumer that he/she would not be liable for the damages, the ability to control the machine - modify the programs without the need to ever contact the service provider. It was also pointed out that the users would feel more like the appliance are theirs as time passes and they get used to them, or when they invest some money in them.

The participants were also asked to compare the feeling of ownership towards the washing machine (and a dryer) to a different product. It seems like it is easier to accept the non-ownership of a functional product such as a household appliance than it would be in the case of a product that consumers also value for other aspects than its function.

> *"A car I like, a washing machine is just something I need."* (A10)

Another factor seems to be error-proneness. A washing machine or a tumble dryer is seen as less prone to errors than a car, therefore the user does not feel like he/she must be that careful. On the other hand, a car charger for an electric car was given as an example of a very simple product where nothing could break, and the user would be less afraid of being liable for some damages than in the case of renting a washing machine. In addition, it was pointed out that a product such as a bed might be too personal to rent.

### *Sustainability*

The testers did not receive any written sustainability-related information, but when they were recruited for the test, they were introduced to the ReCiPSS project and provided the link to the project webpage. However, most of them claimed not to have received any sustainability-related information from the company. This was therefore an opportunity to investigate how they perceive the sustainability of the products and the renting model on their own.

Most of the comments of those who believed the offering is sustainable revolved around the business model - the participants mentioned that the lifetime of the appliance would be prolonged due to regular maintenance, and that it would be given a second life which is not necessarily the case of privately owned washing machines and dryers, or that they would have the possibility to switch to a more sustainable machine. Some product-related aspects were also highlighted such as the fact that professional appliances should last longer and that the washing machine adjusts the time of the wash according to the load.

> *"I definitely feel like this is a more sustainable product, instead of just use and throw out which is often the case – as I said earlier, it is very cheap to buy a washing machine and a dryer, for most people right now, it's easier to get a new one than fixing it. This way, it can be used more times and it gets fixed if it is broken."* (A9)

Nonetheless, doubts about the sustainability of this offering also arose. It was suggested that a tumble dryer is not a very environmentally friendly product in itself since it is not necessary to use one. As for the renting model, some participants struggled to see the difference in comparison to buying, arguing that "*it's the same product doing the same thing*" (A3). Part of the testers could not assess the issue of sustainability, due to a lack of knowledge or information.

In terms of information the testers would like to receive in this regard, three main categories arose from the interviews. Most of the testers mentioned some concrete information that would help them judge the sustainability, such as what type of raw material was used in the production, product specifications, the lifetime of a professional machine compared to a regular one, a comparison with other brands in the industry, energy consumption, which was also mentioned with regard to costs of different programs - information that would also be appreciated. The participants also expressed interest in knowing what happens to the appliance at the end of life, how the company makes sure it is repaired and how many times the appliance has been refurbished. Sustainability-related information could not only be helpful in decision-making but also, as stated by one of the testers "*just to know that you´re making some kind of a difference when engaging in these programs*" (A13), suggesting this kind of information could play a role in self-confirmation.

The second category of information the testers would be interested in comprises the information explaining why the product and service are sustainable. The last category relates to the information on how a customer could use the appliances in a more sustainable manner. However, it should be mentioned that not all the testers considered the topic of sustainability as important to them, some stating it was important, but not as much as the price.

### *Connectivity and usage data*

The testers were also asked about their feelings with respect to the fact that the appliances are connected to the Internet and collect their usage data. Most respondents did not express serious concerns about the data collection, reasoning that nowadays, connectivity is very common, or that the data about their washing is not very personal. At the same time, it was believed that the company is using the data only for relevant purposes. It was also suggested that knowing that they are contributing to improving the product or service can inspire positive feelings. However, the testers also mentioned that they would like to have access to their usage data to be able to improve their washing patterns.

> *"I actually believe that the data is actually used to improve how washing can be done in the future. It's not that big of a deal to tell you how much I wash. It's nice to know that the data can contribute to making future programs and appliances more efficient."* (A1)

One tester with a background in data security mentioned having created a guest network for all the IoT appliances as a precaution if anything was to be hacked. The others did not take similar precautions but mentioned several red lines - cases in which they would not be at ease with the connectivity. These concerned cases where the appliances would be equipped with a camera or a microphone, a two-way connection, meaning that a user would have a response from the company through the washing machine, as this was considered as someone *"entering in their house"* (A10). Some testers would also be reluctant to share more detailed data about washing, and even more so the data beyond washing patterns, such as online activity, for marketing purposes.

> *"…Like what kind of washing you're doing, how full the machine is and things like that – some things would be more personal – because of the times we're living in – sometimes, I would almost feel guilty for only washing half a load."* (A11)

## Discussion and Conclusion

The purpose of this paper was to collect and analyze the feedback from the pilot test of an access-based business model for washing machines and tumble dryers. The benefits and disadvantages were consistent with those cited in the Introduction section. The business model was praised for providing convenience and security since everything is taken care of by the service provider, flexibility, predictable costs, and prolonged product lifetimes. Giving users access to professional appliances was also highly appreciated, showing that the product part of the offering is also important and likely presents added value to the users. The main concern seemed to be the expected total costs and, for some participants, the absence of ownership.

The concerns raised in the literature (see e.g. Ploos van Amstel et al., 2022) about non-ownership leading to less careful handling did not seem to be valid, however, in this case, more careful behaviour towards a rented product was mainly motivated by fear, which is probably not the feeling a company wants to induce in its customers. Moreover, the behaviour might change when these concerns are alleviated, for instance, by an experience of the service provider repairing the products in any case. Inducing psychological ownership might be a preferred solution, which, according to the results, could be influenced by the place where the product is used, the way it is acquired and used, freedom to use and modify it, access to usage data, assurance about not being liable for the damages, time, and money invested into the product.

Consumers expressed interest in various kinds of sustainability-related information; concrete information to help them assess the sustainability, an explanation to enhance understanding of why the offering is sustainable, or some guidelines helping them to use the appliances more sustainably. Although this might place greater information processing demands on the company, it could support consumers in their decision-making, and moreover, enhance self-confirmation of pro-environmentally oriented consumers (see e.g. van Dam and Fischer, 2015).

It seems like consumers are getting more and more at ease with connectivity as smart technologies become part of their everyday lives, however, it depends to a large extent on the degree to which the data is considered personal, and the trust towards the correct use by the company. It was also shown that some users might have a positive attitude towards providing data to improve products or services. While this feeling might be stronger in a testing setting, it might be worthwhile to let regular customers know if they are contributing to a similar cause.

The main limitation of this research lies in the fact that not all the conditions of the testing agreement were identical to a real commercial setting, mainly because the testers had access to the appliances free of charge. In addition, some consumers‘ attitudes could have been influenced by the fact that they were part of the test, not regular customers. Moreover, the sample was only limited to testers from the Danish market. Further research could attempt to overcome these limitations.

# The Repair Shop 2049: Co-Designing Sustainable and Equitable Transitions for Smart Device Repair with and for Local Communities

**Michael Stead[(a)], Matthew Pilling[(a)], Tom Macpherson-Pope[(b)], Paul Coulton[(a)]**
a) Lancaster University, Lancaster, United Kingdom
b) The Making Rooms, Blackburn, United Kingdom

**Keywords**: Right-to-Repair; Internet of Things; Circularity; Socio-technical Imaginaries; Design for Transitions.

**Abstract**: *The Repair Shop 2049* was a pilot research project which explored the limitations of current *Right-to-Repair legislation* which does not account for the repair of 'smart' *Internet of Things* (IoT) devices. It is estimated that by 2030, there will be over 30 billion 'smart' Internet of Things devices in active use worldwide. Unfortunately, with their lifespans designed to be short, most current IoT devices will end up in landfill in the form of electronic waste. Using the notion of a future high street 'Repair Shop' as its lens, the project team collaborated with partner *The Making Rooms*, Blackburn's community digital fabrication lab, to bring together key stakeholders, including repairers/makers, civic leaders, device end-users and manufacturing representatives, to collectively envision pathways for developing new localised, sustainable IoT device repair ecosystems and circular economies. This paper outlines how the project used novel design research approaches *co-design* and *speculative design* to better understand how citizens' might be empowered to increase IoT device Right-to-Repair within their local communities. We conclude by presenting elements of our findings including an initial vision for a *Localised IoT Device Circularity* framework as co-created with research participants, and a wider *Socio-technical Imaginary for a IoT Repair ecosystem* which illustrates the independent and interdependent relations between *bottom-up* and *top-down* stakeholders that must be negotiated to improve IoT device repair.

## Introduction

In 2021 alone, the world generated 57.4M tonnes of electronic waste (e-waste), a figure which is expected to increase to 74.7 by 2030 (Forti et al, 2020). Mirroring the EU's *Circular Economy Action Plan* (2020), to stymie product obsolescence the UK introduced *Right-to-Repair* (R2R) legislation in July 2021 (Conway, 2021). Whilst the R2R is undoubtedly a step forward in tackling obsolescence and e-waste, the legislation's efficacy is reliant on consumers availing themselves of this right. Given that repairing and maintaining devices will often require specialist knowledge and tools, it is presently difficult to assess how effective this right may prove to be in practice.

This deficiency is compounded by the rapid rise in the unsustainable consumption of so-called 'smart' *Internet of Things* (IoT) devices (Stead et al, 2019). It is estimated that by 2030, there will be over 30 billion active consumer IoT devices worldwide (Vailshery, 2022), yet the current R2R legislation does not account for the repair of IoT repair. Furthermore, IoT devices like phones, voice assistants and wearables (Figure 1) are susceptible to *systemised obsolescence*, in that they can easily become 'bricked' or inoperable when their physical hardware no longer supports the latest software or other changes to digital functionality (Stead & Coulton, 2022).

Thus, to empower citizens and their communities with the capacity to effectively increase IoT product repair, manufacturers must be compelled to create devices which bake in hardware and software repairability. In addition, councils and governments must also invest in accessible community repair infrastructures and facilitate local enterprise in innovating new affordable repair support services. Crucially, transitioning to potential futures which proactively 'level up' the R2R by fostering citizen-focussed repair cultures will require the design of new socio-technical ecosystems which leverage ongoing engagement and collaboration between a wide variety of stakeholders including repair experts, technologists, civic leaders, policy makers and indeed, publics.

**Figure 1. Everyday IoT devices. © Various, n.d.**

This short paper outlines our pilot project – *The Repair Shop 2049* – which explored how novel design research approaches including *co-design* (Sanders & Stappers, 2014) and *speculative design* (Coulton et al, 2017) could be harnessed to better understand how citizens' might be empowered to increase IoT device R2R within their local communities, as well as start to develop the socio-technical ecosystems needed to support these activities.

## Co-Designing Sustainable and Equitable Transitions

To start to investigate IoT repair, the research team collaborated closely with *The Making Rooms*, a community fabrication lab based in Blackburn, a post-industrial town in the North-West of England. *The Making Rooms* provides the local community with access and training to a variety of digital creative technologies, activities and skills. For example, citizens can learn to 3D print their own designs, code on open-source hardware and explore more traditional craft techniques like screen printing (Figure 2).

Given this inclusive context, the democratic approach of co-design (Simonsen & Robertson, 2013) was considered an appropriate method to utilise to generate research insights. We accordingly ran a series of co-design workshops with key stakeholders including repairers/makers, civic leaders, manufacturing representatives and citizen device end-users.

**Figure 2. Community, creativity, technology: The Making Rooms. © Authors/The Making Rooms (2022).**

To do so, we appropriated Sanders & Stappers' (2014) 'co-design framework' for the substrate for our workshops' delivery. Our augmented version of this framework centres on transitioning to sustainable and equitable futures and can be seen in Figure 3.

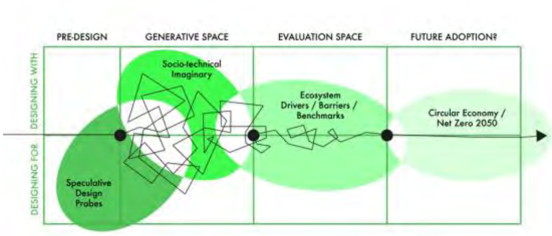

**Figure 3. Co-Designing Sustainable and Equitable Futures framework. © Authors, after Sanders & Stappers (2014).**

Tskeleves et al (2017) stress that it is crucial to include citizens in the developmental phases of technologies, policies and infrastructure that will ultimately have a direct impact upon said citizens when such interventions eventually come into effect across society. Further, empowering people in this way means that they can contribute their own personal experience and knowledge to the discussions and insights that are generated within the creative, collaborative environment (Steen et al, 2011).

## Speculative Repair

To help facilitate our discussions with stakeholder regards future IoT R2R, we incorporated a series of repair-based speculative design probes into the workshops. Sanders & Stappers (2014) contend that this speculative approach allows researchers to create a 'generative space' for both 'designing with' and 'designing for' their participants. We specifically used the speculative design technique *Design Fiction* (Coulton et al, 2017) to create our probes. Our approach built on previous speculative IoT research such as the *Toaster for Life* project (Figure 4) – a fictive IoT device that challenges today's unsustainable IoT status quo by envisioning a mass-produced connected device that is also repairable and reusable through integrated emergent tech including open-source hardware/software, 3D printable modular parts and locally sourced biomaterials (Stead, 2016).

**Figure 4. Toaster for Life – a speculative sustainable IoT device. © Stead (2016).**

We introduced our 'ice breaker' speculative probe – the *Smart Device Bingo game* (Figure 5) – at the beginning of the workshops. We wanted to better understand what types of IoT devices were owned by the participants, which electronic products they believe to be covered by the current R2R, and which devices should be potentially connected to the internet and made 'smart' in the future.

**Figure 5. Smart Device Bingo – a speculative co-design workshop activity. © Authors (2022).**

Secondly, we installed what we termed a *Self Service IoT Repair Station* into the workshop setting (Figure 6). Seeking to visibly demonstrate the range of equipment and expertise required to carry out localised IoT repair, participants were able to tangibly engage with this probe. This 'speculative enactment' technique drew upon Elsden et al's (2017) work in particular.

**Figure 6. Speculative IoT Repair Station. © Authors (2022).**

Figure 7 depicts the outcome of our third speculative activity. We asked participants to work together to identify the key stakeholders – the 'who's who' – required to build an effective and resilient future local IoT repair ecosystem.

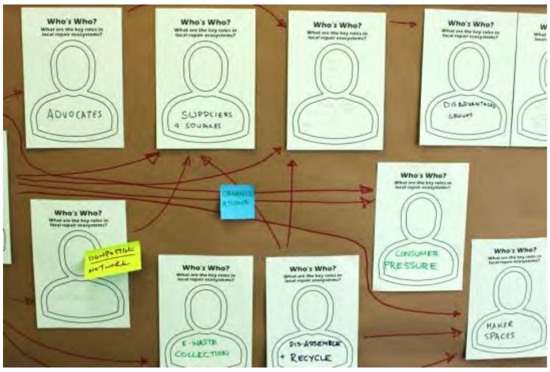

**Figure 7. Who's Who? in Local IoT Repair. © Authors (2022).**

Ultimately, our probes were a means to provoke discourse and ideation practices amongst the workshop participants (Knutz et al, 2014). As Huusko et al (2018) emphasise, such probes can be "used as a workshop tool [but] while the workshop context creates certain needs for the tool, [the probes] can help in building the workshop."

## Analysis

Our 2 workshops with 21 participants produced a gamut of qualitative data. To map and identify key insights from this data, we employed the method *thematic analysis*. Gibbs (2007) explains how this technique can be harnessed to code and index participants' qualitative data, and then categorise the material in order to draw together 'common themes.' Unlike quantitative data, qualitative insights can be strongly reflective of constructivist worldviews and thus, often convey participants' socially constructed nature of reality (Rampino & Colombo, 2012). This attribute is important for our research as we wanted to better understand participants' current experience of IoT repair, as well as, their perceptions and requirements for how it can be improved in the future.

We followed Braun & Clarke's (2006) established *thematic analysis* process of *data familiarisation* and *manual iterative coding*. Due to the dataset's size, it is not possible to detail here all of the collected qualitative material nor the full coding process in this short paper. However, a selection of our coding during the mapping process on a collaborative board can be seen in Figure 8.

**Figure 8. Thematic analysis of workshop data. © Authors (2022).**

## Key Findings

Through our analysis, we identified six key themes. Whilst there were a number of other insights covered, the six themes represent the most prominent recurring topics that were both discussed between multiple participants. Braun & Clarke (2006) describe such an outcome as "patterns of shared meaning underpinned by a central concept."

1. The Difficulties of Repair
Participants discussed how devices' warranties often become void if repair work is attempted by anybody other than the original manufacturer. This annulment can often be triggered even through initial diagnostics to ascertain the root of the problem. Third party repairers were therefore determined to be risk – and therefore repair – averse due to the fears of evoking liability and negating customer warranties. Interestingly, there was also growing concern that should devices become more easily repairable, they could consequently become less reliable and durable due to changes or even deterioration in their physical and digital specifications.

2. Changing Attitudes
Participants felt changing environmental attitudes are likely the result of increased public awareness surrounding the global challenges that modern societies currently face. The prospect of the broadening EU their R2R legislation to include IoT devices was also raised and could lead to reduced e-waste. It was also posited that such a move could also force the hand of the UK government to follow suit and make similar amendments.

3. Opportunities for Education
The participants felt there is potential to improve repair knowledge and education particularly across UK STEM subject curriculums (Science, Technology, Engineering and Mathematics).

4. Distrust in the System
Participants displayed an evident 'distrust in the system' regards both IoT manufacturers' ongoing unsustainable practices, and the lack of local IoT repair infrastructures. They feared the wider introduction of restrictive software by manufacturers to artificially impinge upon – or 'throttle' – their devices' capabilities and consequently limit their hardware and battery lifespan over time. There was also disappointment regards poor local e-waste collection, as well as anger towards the nefarious practices of privileged Global North nations who offset e-waste figures by shipping it to Global South countries rather than improving repair practices.

5. Friction
The term ‘friction’ was used to describe the barriers faced when trying to dispose of their e-waste in a sustainably appropriate manner. There is a collective ‘want to do the right thing’ but it was often unclear what this positive move could or should be and how they might initiate such a shift. They argued improving public awareness would better equip UK communities with basic knowledge for understanding both their repair rights and how to discern if an IoT device is likely to be repairable or requires further investigation from expert repairers.

6. Local Solutions
Collecting e-waste from residents and/or refuse centres for refurbishment and materials and components recovery was posited. Renewed devices might be sold in charity shops, while harvested parts could be dispersed for reuse or recycling. This network could run in conjunction with existing local council and charity networks.

## Co-created R2R Futures

Working with *The Making Rooms* allowed us to focus on a situated context for designing future IoT R2R. Through this context, we were able to better assess and understand the effectiveness of current R2R legislation amongst citizens and communities, as well as consider how far the law must evolve to include IoT repair, which stakeholders should be involved in such developments, and to what extent. In addition, this approach enabled us to begin to consider the role that design-led research can make in facilitating such social and environmental transitions – both in practical and theoretical terms.

### *Localised Circularity*

As well as being effective forums for applying speculative designs, Lyckyi et al (2018) note how participatory activities can also be employed to facilitate “the creation and use of” subsequent speculative design proposals. As depicted in Figure 7, participants were asked to work together to speculate in regards what a future local IoT repair ecosystem might look like – *specifically, could they collectively envision who the key stakeholders in such an ecosystem might be?*

This process led to the co-creation of a *Localised IoT Device Circularity* framework. Figure 9 depicts a graphic iteration of this speculative ‘closed loop’ vision. It aims for the minimum amount of e-waste to be dispersed to recycling centres, or worse, landfill, by integrating a combination of sustainable channels and responsible stakeholders. It visualises our participants’ main concerns regarding the relationship between R2R and IoT devices.

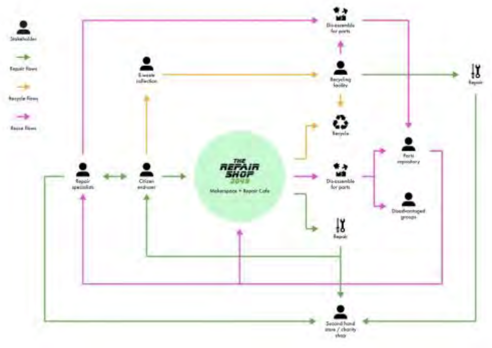

**Figure 9. Localised IoT Device Circularity framework. © Authors.**

### *Repair Imaginaries*

The adoption of systemic lenses when considering contemporary socio-technical challenges is seen as increasingly critical to designing and enacting sustainable and equitable futures (Ceschin & Gaziulusoy, 2016; Design Council, 2021). Mattern (2018) concurs, noting how, to manage care and repair of modern yet often disposable technologies, *‘maintenance has taken on new resonance as a theoretical framework, an ethos, a methodology, and a political cause.’* Reflecting this need, we developed a *Socio-technical Imaginary for a IoT repair ecosystem* (Figure 10), based upon the workshop data.

**Figure 10. Socio-technical Imaginary for a IoT Repair Ecosystem. © Authors, after Coldicutt, Williams & Barron (2021).**

To make IoT device repair truly effective on a local level, wider stakeholders would also need to be engaged and galvanised. Figure 10 illustrates the workshops' participants' strong desire for IoT repair practices, skills and technologies to be made accessible by building channels and connections between multiple 'glocal' stakeholders. Core to this vision are key agents of the *open movement* – *Fab Labs* and social innovation like *The Repair Shop 2049* vision – as well as more mindful manufacturers like *Fairphone* (2023) and *Nokia* (2023).

The imaginary also illustrates the ongoing interplay and tensions between the *bottom-up* and *top-down* actors. Due to this complexity, Coldicutt et al (2021) stress how *bottom-up* endeavours are "not always optimised to capture disparate weak signals [and] are often convened to deliberate on issues that can be observed or anticipated by those with traditional power." This tension, they contend, places limits on the potential for alternative 'unofficial' futures to open up. As we move forward, we hope that by listening to a broad spectrum of stakeholders, we can respond to weak signals and collectively challenge the current R2R legislation to co-design resilient IoT repair futures.

## Conclusions

Through this research, we have revealed sevral drivers and opportunities that our stakeholders foresee as necessary to scale up IoT R2R practices and infrastructures on a local level. Equally, key barriers and risks were also identified. A key issue is the lack of public awareness of the current R2R and how it falls short with regards to supporting better repairability of existing IoT, and the volumes of devices that will proliferate society in the years to come. Having said this, the workshops importantly confirmed that there is huge community enthusiasm and drive to make local sustainable change.

Using socio-technical imaginaries as a design frame is a particularly effective approach for creating a shared vision of the social, technological, economic, political, and environmental impacts that must be negotiated to achieve constructive, collective change (Jasanoff, 2015; Speed et al, 2019). This method also corresponds with Ceschin & Gaziulusoy (2016) who argue that while the sustainability of individual products and services is important, we must start to design more holistically for the wider infrastructures and ecosystems that give rise to problems like e-waste. Our design-led approach helps us respond to this challenge. It allows us to begin to explore the futures of local social capital, economics, employment and policy design, and how these factors must all be thoroughly considered, and likely redesigned, to enact better IoT repairability.

Consequently, we contend that our findings, although emergent, begin to contribute to growing discourse which calls for community adaptation towards Circular Economy principles (Ellen MacArthur Foundation, 2021) to redress e-waste as well as wider international imperatives to achieve Net Zero 2050 decarbonisation targets (Global Climate Action, 2020; IPCC, 2021).

## Future Work

This preliminary research has helped to lay the foundations for impactful follow-on work (in the form of further funded research) through which the research team will continue to explore the convergence between IoT R2R ecosystems, sustainable socio-technical development and citizen-driven innovation. Next steps will include new workshops to further solidify the granular connections between key stakeholders, supply chains and physical-digital resources. To aid this process, we will also produce more advanced speculative design probes that critique the limitations of today's R2R legislation, while at the same offer potential visions for more sustainable and equitable repair futures.

## Acknowledgments

This work was conducted in conjunction with colleagues at *The Making Rooms Blackburn* as part of the *Fixing the Future: The Right to Repair and Equal-IoT* research project which has been funded by the UKRI EPSRC Equitable Digital Society grant number EP/W024780/1.

**Keywords**: Product Design, Li-ion battery, Life Cycle Assessment, Software, Digitalization.

**Abstract**: The determination of a product's environmental sustainability during the development phase can be accomplished through the Life Cycle Assessment (LCA) method. However, the consideration of environmental impacts, such as global warming potential, resource consumption or water scarcity, is challenging due to limitations in data, know-how, and time. To mitigate these challenges, digital and data-driven solutions can be implemented. Within this case study on Li-ion batteries, a flexible and user-friendly assessment tool is being developed to assist product designers determining the key environmental impacts and identify the sustainability hotspots throughout its life cycle. An environmental LCA for Li-ion batteries is performed combined with automated digital solutions to ease data acquisition and calculation of meaningful results. The goal of this study is to create a parametrized LCA model with BOMs (bill of materials) for Lithium-ion batteries and customize the software to suit the needs of product designers.

## Introduction

Most of the environmental impacts of a product are predetermined through the product development phase. A prospective life cycle assessment can support conscious decision-making during this stage, which ideally results in a more sustainable product. However, the integration of environmental sustainability aspects is challenging due to limitations of data, know-how, and time. Digital and data-driven solutions can help mitigating these challenges.

This study is part of the research project IDcycLIB (**I**nnovation platform of a green, **d**etectable, and directly re**cycl**able **l**ithium-**i**on **b**attery, 03XP0393A-J) that contributes to the goal of reducing the primary raw material demand of lithium-ion battery (LIB) "cells by providing a sustainable and industry-ready concept for battery cell production, recycling and reprocessing" (Fraunhofer ISC, 2021).The battery use case chosen for this study plays a key role in enabling shifting from fossil-fuel-based mobility to electromobility and is widely discussed due to the upcoming EU battery regulation.

In the IDcycLIB project two types of life cycle assessment are conducted: a linear LCA, focusing on the immediate support of the project specific green LIB developments and a generic LCA focusing on the development of a flexible tool for product designers. The scope of this study is the latter. The overall goal of this study is to conduct an LCA of a LIB following a generic modelling approach. Such a model is built in a way that different variants of one product or complete product portfolios can be calculated by means of one model. Therefore, products with various adjustments e.g. different Bill of Materials (BOMs), production processes or end of life processes can be assessed with one model. This enables a fast and easy calculation of product variants.

As a prerequisite for performing the generic LCA, this paper focuses on the methodology for building the generic LCA model.
The main elements to develop the generic model are: A) conceptualizing a parametrized LCA model for LIBs as a prerequisite for the generic model, and B) adjusting the iPoint Product Sustainability software (where needed) for better considering the product designers' needs. The web application iPoint Product Sustainability is a user-friendly tool intended for non-LCA experts. The software retrieves the LCA models (via an Umberto interface) and allows for assessing product's environmental impact (iPoint-systems gmbh, n.d.).

Conducting an LCA on new technologies and processes is challenging, as the technology itself is immature and comprehensive data is hardly available (Schöggl et al., 2017). However, sustainability challenges related to new technologies and systems can be best addressed, if recognized in the early development phase. Therefore, a modular approach is chosen to build the generic LCA. This allows broad coverage of parts and enables the subsequent integration of new components and/or data information and can therefore be applied in similar battery projects.

Generic modular LCA modelling is a valuable instrument to improve new technologies and support the preliminary assessment of the environmental impact. It provides a platform to evaluate and improve the materials and processes of a LIB and its possible recycling processes (direct, pyrometallurgic and hydro metallurgic). Similar to a linear LCA approach, the life cycle inventory (LCI) of a generic model consists of the energy and material flow data within the defined boundaries of the LIB system, but the LCI data changes, depending on the parameters defined by the model's user.

This research contributes to enhance the understanding of the methodology concerning generic modeling of batteries using the iPoint Product Sustainability software. The generic model could also be extended to other battery types or components to support a product designer's sustainable decisions.

## Methodology

Umberto (Version 11) and the ecoinvent database (Version 3.9) (ecoinvent, n.d.) are used for the linear and generic LCA modelling, according to the DIN EN ISO 14040/14044 (International Organization for Standardization, 2020) and the ILCD manual (Joint Research Centre, 2013).

According to EN ISO 14040/14044, the *Goal and Scope* of the LCA model should be defined before the start as necessary prerequisites to ensure a consistent assessment of environmental impacts. This includes the definition of system boundaries, assessment approach and indicators, functional unit, impact categories, weighting and decision-making between the selected indicators. The boundaries of this study are defined together with the project partners and include all stages of a traction battery value chain; i.e. from the selection of materials for a battery's electrodes and electrolytes, production of electrodes and cells, as well as End of Life (EoL) considerations (recycling options, regeneration of functional materials).

During the *Inventory Data Collection,* information on materials, manufacturing processes, and EoL processes are included through expert estimations and/or calculations using interviews, databases, and literature data. The life cycle inventory data is regularly being discussed with project partners and, if necessary, modified in iterative steps (e.g., if the data basis increases or processes change). The *Impact Assessment* is conducted by the tool user (industry partners in the battery sector) in order to identify the most ecologically sustainable process and circular economy paths.

The generic model was built independently of the linear LIB LCA model with consideration of additional data (e.g. other materials and/or geographical conditions). We identified the following steps to develop the tool concept:

1. Structural Framework: Crenna et al. (2021) proposed a modular LCI approach to enhance the comparability of LIB LCAs by increasing both transparency and flexibility. This approach serves as the structural foundation for the present study while ecoinvent data sets on LIBs are used to fill the structure with generic data. Figure 1 shows a module example.

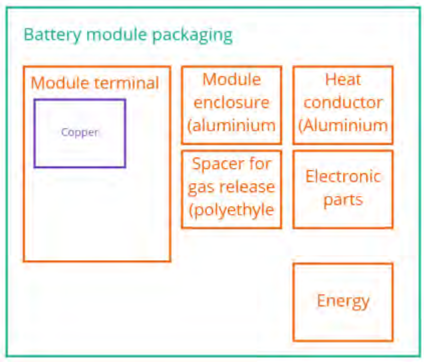

**Figure 1. Excerpt of generic LIB modular concept overview "Battery module packaging".**

2. Data collection:
Primary data from project partners as well as secondary data like ecoinvent, Everbatt (Dai et al. 2019) and LCA studies were used to build the LCA model. In workshops with industry partners, relevant battery materials were identified, e.g. different cell chemistries, electrolytes or housing materials. Additionally, information on the most relevant battery parameters to be considered in the modelling were identified, e.g. energy density, cell mass or battery lifetime.

3. Modelling and tool development:
A parameterized Umberto model is uploaded into iPoint Product Sustainability. By parameterizing data in an Umberto model it is possible to easily assess the environmental impact of different variables and product components/materials. Therefore, variables (e.g. cell type, mass, energy density, etc.) can be changed globally in a model without having to change them in each process step. These parameters can also be modified in Product Sustainability after uploading the model in the web application (see Figure 2a).
Another possibility to structure a model in Umberto is through "production orders" (see Figure 2b). Production orders use the structure of BOMs and describe the manufacturing of a product or component. They are linked to a defined route through the production system along a series of work places, machines or unit processes. Most commonly, production orders are used when modeling manufacturing activities. Different production orders can for example be created when comparing different product variants (with different BOMs).

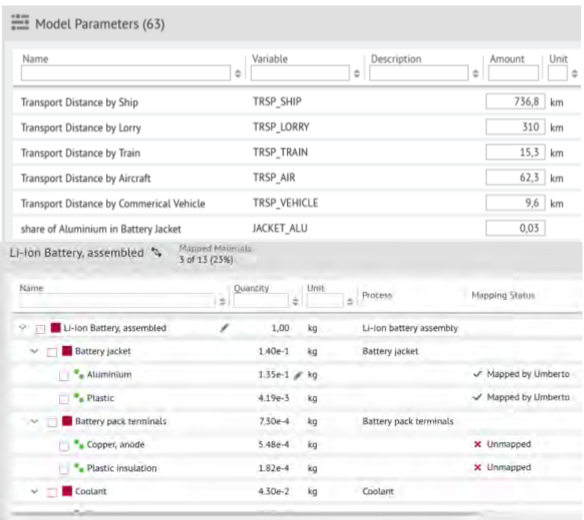

**Figure 2. Example of uploaded Umberto model with a) parametrized data (top) and b) production orders in iPoint Product Sustainability (bottom).**

4. Tool testing and validation: After getting usability feedback from project partners on different approaches (e.g. mix of parameters and production orders) the model will be updated.

## Discussion

A key challenge is to structure the LCA model in a way that allows new modules to be easily integrated. Therefore, an open, expandable structure is the essential characteristic of the developed LCA model. The study focused on achieving this flexible modular structure rather than producing a complete model (covering all possible battery types).

Workshops with stakeholders as well as literature sources allowed to identify the most relevant battery components and processes.
The first model was developed by parametrizing the life cycle inventory data (e.g. mass, energy, etc.). The data parametrization allows defining dependencies between entries. However, the parametrization of the data seems to have limitations in the generic model because it is difficult to retain an overview of the whole system. A proposed solution is to combine parametrization and production orders, including a BOM-structure that can be easily adapted by the user.

## Outlook

Interviews with product designers assured that the tool will enable users without LCA expertise to gain insights into the environmental performance of different product options, e.g. a designer can check the environmental impacts of different material types to identify the most environmental-friendly choice or which battery component is the environmental hotspot and should be analyzed in more detail to identify reduction potentials.

Data availability and comparability for different battery components and processes and the inclusion of circularity aspects into the tool will be addressed in future research.

After completion, a tool validation phase by stakeholders and research partners will allow to: a) identify advantages and disadvantages of parameterized models, models using production orders and models mixing parameters and production orders; and b) determine the ecological advantages of newly developed processes and products.

Different functionalities will be tested to identify the best balance between functionality and usability for the use case of generic models. The Umberto software and the sustainability web application can be extended, including new functionalities that support sustainability decisions of product development in the design stage.

The developed methodology to build the generic LCA model for lithium-ion batteries could be used as a blueprint for other product types, e.g. electrical components.

## Acknowledgments

This project was funded by the program: „Batteriematerialien für zukünftige elektromobile, stationäre und weitere industrierelevante Anwendungen (Batterie 2020 Transfer)“ as part of the roof concept „Forschungsfabrik Batterie“ in the framework program „Vom Material zur Innovation“ of the German Federal Ministry of Education and Research from 27.07.2020 (funding code 03XP0393A-J).

c) Department of Food Innovation, HAS University of Applied Science, Den Bosch, The Netherlands

**Keywords**: Sustainability; Rethink; Redesign; Food waste; Packaging; Trade-off.

**Abstract**: Making food packaging more sustainable is a complex process. Research has shown that specific knowledge is needed to support packaging developers to holistically improve the sustainability of packaging. Within this study we aim to provide insights in the various tradeoffs designers face with the aim to provide insights for future sustainable food packaging (re)design endeavors. The study consists of analyzing and coding 19 reports in which bachelor students worked on assignments ranging from (1) analyzing the supply chain of a food product-packaging combination to (2) redesigning a specific food packaging. We identified 6 tradeoffs: (1) Perceived Sustainability vs. Achieved Sustainability, (2) Food Waste vs. Sustainability, (3) Branding vs. Sustainability, (4) Product Visibility vs. Sustainability, (5) Costs vs. Sustainability, and (6) Use Convenience vs Sustainability. We compared the six tradeoffs with literature. Two tradeoffs can be seen as additional to topics mentioned within literature, namely product visibility and use convenience. In addition, while preventing food waste is mentioned as an important functionality of food packaging, this functionality seems to be underexposed within practice.

## Introduction

The industrialization, production and consumption of food has become more and more separated in time and space, which has led to a need for packaging food (Bruijnes et al., 2020). Food packaging fulfills a whole range of functionalities, from containing and portioning food to providing use convenience, marketing, communication, and transportation (e.g., Santi et al., 2022; Ten Klooster & De Koeijer, 2016). One of the underexposed functionalities of food packaging is food preservation and prolonging shelf life which helps reduce food waste (Guillard et al., 2018). Through these functionalities food packaging can help reduce the environmental impact of food (Wikström et al., 2019; Wohner et al., 2019). This shows the important role packaging fulfills, since packaging accounts for only 10% of the environmental impact as opposed to the food packaged in it, which is 90% (Bruijnes et al., 2020)- at least if recycling at the end of life is done properly.

Both on a European level as well as on national levels the need is felt to make the overall food system more sustainable. Packaging plays an important role in the ambitions to make the food system more sustainable, as it can both prevent food waste and be more sustainably designed itself (Brennan et al., 2021). In the Farm to Fork strategy, for example, the European Union not only focuses on more sustainable material use, reuse, and recyclability of packaging, but also stresses the focus on preventing and reducing food waste (European Union, 2020). On a national level, the Dutch Plastics Pact committed to replacing single-use plastics for more sustainable alternatives, reducing the use of plastic with 20%, and improving recyclability of packaging by 2025 (Ellen MacArthur Foundation, 2019; Ministry of Infrastructure and the Environment, 2019).

Packaging design can become a complex process when having to balance between all the functionality and sustainability requirements. Designers face a web of tradeoffs when it comes to sustainable packaging design as they must consider factors such as extending product shelf life and improving consumer perception (Ten Klooster & De Koeijer, 2016).

State of the art research shows that specific knowledge that is needed to support designers' considerations when developing sustainable product-packaging combinations is limited.

With this paper, we aim to provide insights in the tradeoffs in sustainable food packaging design with the aim of supporting designers in making sustainable packaging (re)design decisions.

## Method

To uncover the tradeoffs, we gave students sustainable food packaging assignments ranging from (1) analyzing the supply chain of a food product-packaging combination (systems level) to (2) redesigning a specific food packaging (product level) according to different circularity strategies (e.g., rethink, reuse, recycle). The cases included sustainable redesign of agri-food (e.g., tomato (figure 1) and bell pepper packaging), portion packaging (e.g., margarine) and ready-to-eat meals (e.g., smoothies and microwave meals). Within this paper we focus on the analysis of agri-food-packaging cases to create a complementary list of tradeoffs, as we only managed to gather a wide range of assignments within this category. The students came from various educational backgrounds ranging from Industrial Design Engineering, Packaging Design and Food Innovation spread over three universities of Applied Science in the Netherlands: HAS green academy (HAS UAS), The Hague University of Applied Science (THUAS) and Amsterdam University of Applied Science (AUAS). These three institutes collaborated in a Dutch research project called “Goed Verpakt” (translation: Well packaged). We selected both bachelor graduation reports as well as reports from minor courses about sustainable packaging (design) (see table 1). We analyzed a total of 19 bachelo-level student reports.

| Assignment | Institute | Type of report | Reports (#) |
|---|---|---|---|
| Supply chain analysis of chicory and apples | HAS UAS | Bachelor Graduation | 1x |
| State of the art in online and offline agri-food packaging | HAS UAS | Bachelor Graduation | 1x |
| Sustainable redesign of cherry tomato packaging | THUAS | Minor | 11x |
| Sustainable redesign of bell pepper packaging. | AUAS | Minor | 5x |
| Redesign of soft fruit (e.g., blueberries) packaging focusing on the use of paperboard packaging | AUAS | Bachelor Graduation | 1x |

**Table 1. Overview of Agri-food packaging reports.**

**Figure 1 . Cherry Tomato packaging. Foto credit: Greenco.**

To uncover the tradeoffs packaging designers face when creating sustainable food packaging we coded the reports. The written text proved to be most valuable for our sense-making efforts. Hence, we coded the written information in the reports. We applied the Gioia methodology (Gioia et al., 2012) to ensure qualitative rigor during the analyses process.

During the first step we stayed close to the terminology used by the students in their reports. Through several iterative rounds in which we assessed the essence of each quote so that we could cluster them into first order codes and later second order themes. We used so-called *phrasal descriptors* (e.g., unique packaging shape vs. efficient transport).

To ensure intercoder reliability, two researchers, supported by a research assistant, read each of the reports separately and wrote down all the sustainability tradeoffs that they encountered. We organized two work sessions during the analysis process to gather input from the full team of 8 researchers working on the Well Packaged research project). In the first session on December 2, 2022, we asked the researchers to go through selected reports and write down which tradeoffs they encountered for comparison. In the second session on January 27, 2023, we asked the researchers to categorize the additional tradeoffs that we had found. During this session the researchers also gave feedback on the definitions of the first order codes and the relevance of the findings. We also asked them to check whether the formulated tradeoffs were actual tradeoffs and to categorize them (table 2).

| Phases | Activities | People Involved |
|---|---|---|
| Report Analysis part 1 | First round of analyzing report and formulating tradeoffs | Two main researchers |
| Pressure cooker | Analyzing six selected reports | Extended research team |
| Report Analysis part 2 | Second round of analyzing reports and formulating (additional) tradeoffs | Two main researchers supported by research assistant |
| Work session 2 | Discussing the definitions of the tradeoffs found in the second round as well as categorizing them and discussing the relevance | Extended research team |

**Table 2. Overview of research Process.**

## Results

In total we identified 71 first order concepts (a summary of the codes is presented here) and 16 second order themes, which were clustered in a total of 6 aggregated themes (see table 3). We did not find different tradeoffs between reports in which students applied different circularity strategies (e.g., rethink, reuse, reycle).

| First order codes | Second order theme(s) | Aggregated themes |
|---|---|---|
| • Replacing plastic with cardboard based on customer perception. (*Bell pepper reports; Cherry tomatoes reports; Soft fruit report and State of agri-food packaging report*)<br>• Considering replacing packaging materials based on the customer's perception of sustainability instead of considering overall environmental impact across the full life cycle *(Cherry tomatoes reports)* | • Making packaging choices based on the consumers' perception of sustainability vs. scientifically proved sustainability | **Perceived sustainability vs. Achieved sustainability** |
| • Choosing virgin plastic instead of recycled plastics for chicory packaging to prevent the bag from easy tearing during transport and use.<br>• Choosing a thicker material to protect the packaging from tearing during transport during transport (*Chicory and apples report*)<br>• Packaging fruit or vegetables to prevent it from getting damaged during transport *(Chicory, apples, and soft fruit reports*) | • Reducing/Saving material to lower the environmental impact (e.g., recyclability) of the packaging vs. Adding packaging to prevent food waste<br>• Exchanging the material to lower the environmental impact of the packaging vs. Improving recyclability<br>• Exchanging the material to improve recyclability vs. Choosing a material that prevent food waste<br>• Exchanging the material to lower the environmental impact vs. Reducing the weight of materials<br>• Reducing/Saving material to lower the environmental impact of the packaging vs. Adding packaging to meet requirement of stakeholders in the chain<br>• Choosing a packaging shape to prevent food waste vs. Optimizing the packaging for efficient transport. | **Food waste vs. Sustainability** |

**Table 3. Overview of 6 main tradeoffs in agri-food packaging.**

## Discussion

Within this study we identified 6 main tradeoffs in sustainable food packaging. While some of the tradeoffs are new, other tradeoffs are further extensions of tradeoffs formulated within literature.

First, the tradeoff **Perceived sustainability vs. Achieved sustainability** is defined as: choosing packaging materials based on customers' perception regarding sustainability instead of based on scientific research about sustainable application of a specific packaging material. This tradeoff was mentioned by de Koeijer et al. (2017) in the context of different organizational roles whereby desired sustainability goals on strategic level do not always match with the perceived and achieved sustainability outcomes on operational level. Within this study we mainly found a contradiction between the last two types of sustainability. This can be traced back to students working on assignments set by industry clients. Yet, this brings into question the influence of the consumer and the potential green washing effect. To what extent do we need to educate the customer about the intricacies of sustainable packaging?

Second, the tradeoff **Food waste** vs. **Sustainability.** is defined as: optimizing only the packaging as opposed to the whole product-packaging-combination (on system's level) for sustainability. Optimizing only the packaging by, for example, choosing less materials could result in food waste throughout the chain. While literature does mention the impact of food waste as opposed to packaging - food waste accounts for 90% of the environmental impact versus the packaging 10% (Bruijnes et al., 2020) - we could not find literature that extensively mentions the need to sometimes steer away from conventional sustainability guidelines (e.g., reducing the weight of packaging, choosing virgin material instead of recycled material) to prevent food waste.

Third, the tradeoff **Branding vs. Sustainability** is defined as: choosing the function of branding over a more sustainable packaging. This trade off can be found within literature as well. Barriers between achieved and perceived sustainability can be traced back to conflicts between sustainability considerations, and inter alia integration commercial requirements and integration of marketing (de Koeijer et al., 2017). Within our study we found that when the design students focused on redesigning the packaging to make it "look more sustainable" they simultaneously resorted to tactics to add branding surface. This conflicts with general sustainability rules.

Fourth, the tradeoff **Product visibility vs. Sustainability** is defined as: prioritizing visibility of the product in the packaging over sustainability packaging guidelines. This tradeoff is different and should be seen as separate from branding; product visibility was steered by the need to assess the state of the product in the packaging. Within literature we could not find this specific barrier. Yet, an interesting finding within the reports indicated that the way the agri-food products were packaged became irrelevant when they were sold online. This brings into question the need to provide visibility within agri-food packaging.

Fifth, **Costs vs. Sustainability** is defined as: prioritizing saving material and production costs without considering the environmental impact of the sourcing, production, use and end-of life of the material.

It comes down to (1) prioritizing saving material and packaging production costs without considering the environmental impact of sourcing, production, use and end-of life of the material and (2) reluctance to invest in new sustainable packaging innovation. Cost as a barrier for sustainable packaging redesign has been mentioned already in 1992 by Kassaye and Verma (1992) and is still mentioned as an important barrier that can hinder the development of sustainable food packaging (Guillard et al., 2018; Santi et al., 2022). Bruijnes et al. (2020) however stress that although it is hard to put in effort without seeing direct result, it is important to still try and think about the long term.

Last, **Use convenience vs Sustainability** is defined as: prioritizing the use convenience for customers over the actual need to pack certain food items. For example, when it comes to apples which can be found (un)packed in various ways (e.g., unpacked, packed in a tray per 4 or 6, and packed in a plastic bag). This raised the question of the function of the packaging and its environmental impact. Use convenience is one of the elements that is mentioned in literature as a functionality of packaging (Santi et al., 2022). Yet, our study shows that it could in fact hinder sustainable packaging development.

### *Further Research*

First, while not exclusively, this study mainly centered around packaging designers. Yet, in practice, designers are only one of the stakeholders involved in (re)designs packaging. They often receive a specific framed assignment from higher up. This suggest that all involved departments should be made aware of the identified sustainability tradeoffs. One step further would be: management having to work with the stakeholders when developing the sustainability strategy. Further research could investigate how the tradeoffs could be incorporated on a strategic level.

Second, within this study we only looked at student reports. While most assignments were commissioned by real life companies (reflecting which requirements are important to them as well), the outcomes of the reports are influenced by the level of knowledge and experience of the students. Further research should therefore focus on how well the list of tradeoffs resonates with designers in practice and how this list can be used as a tool during the design process.

Third, we expected to find different tradeoffs in the reports in which students applied redesign in comparison to rethink as they would focus on respectively redesigning the existing product-packaging combination vs. looking at system-level solutions. However, the reports did not show differing outcomes. This could be because we only analyzed reports made by students, who are more inexperienced than designers working in practice. Hence, further research should focus on the extent to which the tradeoffs are linked and how applying a systems level circularity strategy such as *rethink* could help to bypass multiple tradeoffs.
Last, the tradeoffs found in this paper were only based on agri-food cases. Hence it would be interesting for further research to what extent the tradeoffs apply to other food packaging categories (e.g., portion and ready-to-eat).

## Conclusion

With this study we aimed to provide a list of tradeoffs that designers face when developing sustainable packaging. Based on the analysis of 19 student reports we found 6 main tradeoffs: (1) Perceived Sustainability vs. Achieved Sustainability, (2) Food Waste vs. Sustainability, (3) Branding vs. Sustainability, (4) Product Visibility vs. Sustainability, (5) Costs vs. Sustainability, and (6) Use Convenience vs Sustainability. On their own, these tradeoffs present challenges when developing sustainable (food) packaging, but they also are related to each other. Fulfilling multiple competing functionalities such as branding, product visibility and providing use convenience can all counteract with each other and with environmental sustainability efforts as it can result in more material use. This makes it even more complex for designers to make clear choices. This first overview of tradeoffs forms a base of knowledge that can help designers in practice make more informed decisions concerning sustainable food packaging design.

## Acknowledgments

This study is part of a Dutch research Project titled "Goed Verpakt" (Well Packaged) in which the HAS University of Applied Sciences, the Hague University of Applied Sciences, and the Amsterdam University of Applied Sciences collaboratively investigate which tradeoffs packaging developers face when they aim to holistically improve the sustainability of food-packaging-combinations. Goed Verpakt is co-funded by Regieorgaan SIA (RAAK-mkb), part of Dutch research council (NWO).

We would also like to thank our colleagues Alex Hanhues and Bente Snäll for supporting us with the data analysis. Next to that we would like to thank the wider *Well Packaged* research team for giving feedback on the first drafts of this conference article.

**Keywords**: Circular economy; Delphi; Design education; Transition; Upcycling.

**Abstract**: Transitioning from a linear economy to a circular economy (CE) requires changes in education at all levels, especially in higher education. The changes in education for the transformation towards CE in both formal and informal settings will eventually inform, inspire, and affect professional practices in industries in a positive way. Aligned with CE, a promising umbrella concept and practice called 'upcycling' is emerging. The concepts and practices of CE and upcycling overlap depending on the diverse definitions of the terms provided by academics and practitioners in various disciplines and sectors in different parts of the world. This has caused some confusions and misunderstanding by some academics and professionals. For teachers and training providers that aim to teach students and professionals about sustainable production and consumption including upcycling and CE, it is beneficial to distinguish between these two concepts. Understanding the interrelationships between them in theory and practice is important to provide researchers and practitioners with a clear guidance and recommendations. This study aimed to explore how we should understand and teach upcycling in the context of CE utilising a Delphi method. This short paper presents the literature review and preliminary analysis results based on the first phase of Delphi: definitions of upcycling and CE, comparisons between upcycling and CE, upcycling as part of CE (or interrelationships between them), and effective ways to communicate the aforementioned contents.

## Introduction

Transitioning from a linear economy (based on take, make, use, and dispose) to a circular economy (CE) (sustainable alternative system based on material circularity (Stahel, 2016)) requires changes in education at all levels, especially in higher education (Kirchherr & Piscicelli, 2019). The changes in education for the transformation towards CE in both formal and informal settings will eventually inform, inspire, and affect professional practices in industries in a positive way (Rokicki et al., 2020; Salas, Criollo, & Ramirez, 2021). Aligned with CE, a promising umbrella concept and practice called 'upcycling' is emerging. Upcycling is an approach to extending the lifetimes of products, components and materials by utilising various CE practices (e.g., 'creative' repair, reuse, refurbishment, redesign, and remanufacturing) to create a product/material of higher quality or value than the compositional elements (i.e., used or waste products, components and/or materials) (Singh, Sung, Cooper, West, & Mont, 2019; Sung, 2017). The concepts of and practices in CE and upcycling overlap depending on the diverse definitions of the terms provided by academics and practitioners in various disciplines and sectors in different parts of the world (e.g., Bridgens et al., 2018; Kalmykova, Sadagopan, & Rosado, 2018; MacArthur, 2013; Sung, 2015). According to multiple anecdotal evidences, this has caused some confusions and misunderstanding by some academics and professionals. For teachers and training providers that aim to teach students and professionals about sustainable production and consumption including upcycling and CE, it would be beneficial to distinguish between these two concepts. Understanding the interrelationships between them in theory and practice is important to provide researchers and practitioners with a clear guidance and recommendations. This study aimed to explore how we should understand and teach upcycling in the context of CE (with the ultimate goal of contributing to the transition to CE) utilising a Delphi method (a series of questionnaires with experts) (Ziglio, 1996).

## Project background

The starting point of this study was the British Science Festival 2022 event, 'Upcycling Station', at Leicester Creative Business (LCB) Depot in Leicester, UK in September 2022. This event was initiated and co-organised by the first author and Dr Mary O'Neill at De Montfort University. Nine global experts in upcycling and CE from academia and industry who are part of the International Upcycling Research Network (funded by AHRC – Arts and Humanities Research Council) made short videos to explain what upcycling is and how it is related to CE to inform and educate the general public. The AHRC-funded International Upcycling Research Network project is run by the first (PI) and second (Co-I) authors. The initial idea was to use the video resources as the basis for developing educational materials for wider dissemination. However, taking into account the limited number of participants and the diversity of the contents, we decided to develop this into a research project involving literature review and Delphi in order to develop more comprehensive and valid educational materials reflecting a wide range of sources of information and expertise.

## Methods

We conducted a literature review between October and November 2022. Using the literature review outcomes, we carried out the first phase of Delphi between February and March 2023.

### *Literature review*

Theoretical, narrative review (Paré, Trudel, Jaana, & Kitsiou, 2015) was conducted using one bibliographic database – Google Scholar – selected for sufficient coverage (Halevi, Moed, & Bar-Ilan, 2017). "Upcycling" and "circular economy" (not as combination) were used as search keywords. We only included journal articles, conference proceedings, and PhD theses written in English using the first 60 search outcomes as the arbitrary cut-off point (no other inclusion or exclusion criteria). From this first screening process, we identified 58 upcycling publications (52 journal articles, 5 conference proceedings, and 1 PhD thesis), and 50 CE journal articles. We then checked titles, abstracts and main body for the content relevance (second screening). During the content screening, we excluded publications that lack theoretical description or discussion on the concept of upcycling or CE, resulting in 52 upcycling literature (46 journal articles, 5 conference proceedings, and 1 PhD thesis) and 42 CE journal articles to be reviewed. We analysed and discussed the contents in terms of definition and concept of upcycling and CE, comparison between them, and their interrelationships. Detailed review methods and processes can be found in the separate review paper, 'Understanding upcycling and circular economy and their interrelationships through literature review for design education' (Sung, 2023).

### *First phase of Delphi*

We designed the Delphi study questionnaire based on the literature review results and asked study participants, 'What would you like to add, change, delete, or improve from the description/table/diagram below?' regarding definitions of upcycling and CE (descriptions), comparison between upcycling and CE (table), and upcycling as part of CE (diagram). There were two additional questions. One was 'What would be the effective ways to communicate the above information (how to define upcycling and circular economy, the comparison between them, and the interrelationship between them) for educational purposes? (e.g., for UG, PGT, or PGR students, industry professionals)' as an open-ended question. The other was 'Please rate your level of confidence that your contribution is accurate below' with five answer options: (i) 99-80% confidence in being right; (ii) 79-60% confidence; (iii) 59-40% confidence; (iv) 39-20% confidence; and (v) 19-0% confidence.

The questionnaire (word document) was sent via email to 46 experts (academics and practitioners) in upcycling and CE who are part of the AHRC-funded International Upcycling Research Network. 15 people (14 academics and 1 practitioner) responded (32.61% response rate) as email reply. They are from 10 different countries of 4 continents (Australia, Botswana, Brazil, Costa Rica, Ghana, Kenya, Sweden, UK, USA, Zimbabwe); 8 females and 7 males. As an incentive to increase the participation rate and as a token of gratitude, three randomly selected participants received £10 Amazon e-voucher.

## Results

*Literature review*

To summarise the review (based on 52 upcycling literature), upcycling was largely described as an effective design-based solution and green practice:

- utilising the materials, components and products that are discarded, no longer in use or about to disposed of.
- incorporating multiple material processes (e.g., 'creative' or 'innovative' reuse, repurpose, repair, upgrade, redesign, reconstruction, refashion, remanufacture, and advanced recycling) involving minimisation of waste and toxicity, saving in energy and water, reduction in emissions and pollution.
- creating the outputs of new/modified products and materials with higher quality and values (economic, aesthetic, and environmental) than the original or compositional elements.

Circular economy (based on 42 reviewed CE journal articles) was largely illustrated as an alternative economic model and industrial system of production and consumption designed to be restorative or regenerative by:

- (i) restructuring the material flows from the linear approach (take, make use, and dispose of) to the circular one (e.g., slowing and closing resource loops or narrowing resource flows); (ii) relying on renewable energy, (iii) minimising, tracking and eliminating the use of toxic chemicals, (iv) utilising applicable principles (e.g., refuse, rethink, reduce, reuse, repair, refurbish, remanufacture, repurpose, recycle, and recover), and (v) actioning in circular product design and production, business models, technology development, cross-cycle and cross-sector collaboration, and supportive environment including policies conducive to CE.
- operated in micro (enterprises and consumers), meso (economic agents in symbiosis), and macro (cities, regions, and governments) levels.
- resulting in environmental benefits such as increased resource/material efficiency and reduced wastes and emissions, as well as socio-economic benefits such as reduced costs for raw materials, energy, waste management and emissions control, and new employment opportunities.

| Upcycling | CE |
|---|---|
| **What** | |
| Effective, design-based solution and a green practice. | An alternative economic model and industrial system of production and consumption designed to be restorative or regenerative. |
| **Input materials** | |
| The materials, components and products that are discarded, no longer in use or about to be disposed of. | Virgin and synthetic materials, components and products that are discarded, and no longer in use or about to be disposed of. |
| **Principles or practices** | |
| 'Creative' or 'innovative' reuse, repurpose, repair, upgrade, redesign, reconstruction, refashion, remanufacture, advanced recycling, and more. | Refuse, rethink, reduce, reuse, repair, refurbish, remanufacture, repurpose, recycle, recover and more. |
| **How** | |
| - Minimising waste and toxicity.<br>- Saving energy and water.<br>- Reducing emissions and pollution. | - Restructuring the material flows from the linear approach (take, make use, and dispose of) to the circular one (e.g., slowing and closing resource loops or narrowing resource flows).<br>- Relying on renewable energy.<br>- Minimising, tracking, and eliminating the use of toxic chemicals.<br>- Actioning in circular product design and production, business models, technology development, cross-cycle and cross-sector collaboration, and supportive environment, including policies conducive to CE. |
| **Outcome** | |
| New/modified products and materials with higher quality and values (economic, aesthetic, environmental) than the original/compositional elements. | - New/improved policies, regulations, guidelines, or governance systems.<br>- New/improved partnerships or collaborations (industrial symbiosis).<br>- New/improved business models.<br>- New/improved supply chain management systems. |

| | |
|---|---|
| | - New/improved production or manufacturing systems.<br>- New products for long-life.<br>- New products for product-life extension.<br>- New biodegradable products.<br>- New products using fewer resources.<br>- Sharing or leasing services (renting, pooling).<br>- Product service system.<br>- New/improved reuse initiatives (e.g., second-hand shops).<br>- Incentivised product return service.<br>- Upgraded products.<br>- Remanufactured or refurbished products and parts.<br>- Repaired products.<br>- Recycled materials.<br>- Recovered energy.<br>- … |
| **Operation** | |
| In micro (enterprises and consumers) and meso (economic agents in symbiosis) levels | In micro (enterprises and consumers), meso (economic agents in symbiosis), and macro (cities, regions, and governments) levels |

**Table 1. Comparison between upcycling and CE.**

We compared between upcycling and CE concepts (Table 1), and realised that the benefits (or end goals) are the same. The common benefits include:

- Environmental benefits such as increased resource/material efficiency and reduced waste and emissions.
- Socio-economic benefits such as reduced costs for raw materials, energy, waste management, emissions control, and new employment opportunities.

From the synthesis of the literature review, we created a diagram to show upcycling as part of CE (or interrelationships between them) (Figure 1). The comprehensive literature review results can be found in the review paper (Sung, 2023).

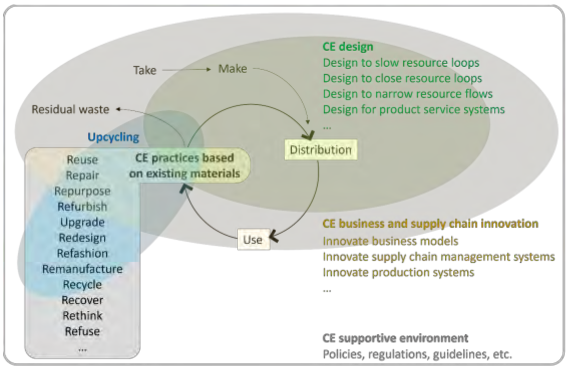

**Figure 1. Upcycling as part of CE.**

### *First phase of Delphi*

The responses (from 15 study participants) were collated and the following revisions and suggestions were made.

Regarding the definition and description of upcycling, most responding experts agreed that upcycling could potentially be an effective design- or process-based solution and sustainable practice to avoid the use of virgin materials:

- Utilising the materials, components and products that are discarded, no longer in use, rarely utilised or about to be disposed of (using both pre- and post-consumer solid waste) and giving them a new purpose
- Utilising material processes/methods (e.g. 'creative' or 'innovative' reuse, repurpose, repair, upgrading, redesign, reconstruction, refashion, remanufacture) involving minimisation of waste and ideally systematic efforts for elimination of toxicity, saving in energy and water, and reduction in emissions and pollution
- Creating the outputs of new/modified products (or artefacts) and materials with higher quality and values (economic, aesthetic, environmental, cultural, and social) than the compositional elements, and creating multiple use cycles of products, components and materials in upcycled products
- Generating alternative consumption and production local systems with strong socio-environmental values that can integrate and reconnect communities and intergenerational relations around sustainable practices
- Oftentimes reclaiming traditional knowledge and skills (e.g. handcrafts, repair, repurpose) and establishing a set of socioenvironmental values around these social practices

Regarding the definition and description of CE, the experts mostly agreed that the circular economy is an alternative, sustainable economic model and production and consumption system intentionally designed to be restorative or regenerative by:

- (i) restructuring the material flows from the linear approach (take, make, use and

dispose) to the circular one (slowing and closing resource loops, and narrowing and facilitating resource flows); (ii) relying on distributed renewable sources of energy; (iii) minimising, tracking and eliminating the use of toxic chemicals; (iv) utilising applicable principles (e.g. refuse, rethink, reduce, reuse, repair, refurbish, remanufacture, regenerate, repurpose, recycle, recover); (v) actioning in circular product design and production, business models, technology development, cross-cycle and cross-sector collaboration, and supportive and equitable environment including policies conducive to CE; (vi) facilitating the inclusion of practices that foster social justice; and (vii) educating the future generations
- Operated across scales including micro (enterprises and consumers), meso (economic agents and enterprises in symbiosis), and macro (cities, regions, and governments) levels
- Resulting in environmental benefits such as increased resource/material efficiency and reduced wastes and emissions, as well as socio-economic benefits such as reduced costs for raw materials, energy, waste management and emissions control, new employment and/or social opportunities, and individuals' sustainable consumption and lifestyles

Regarding the comparison between upcycling and CE, one critical feedback was that as upcycling is part of CE, they are not at the same level and therefore incomparable. The comparison table will need to be radically restructured in such a way that in each category CE description incorporates upcycling description as part, which is one of the next steps beyond the remit of this paper.

Regarding the diagram to show the interrelationship between upcycling and CE, some additions and revisions were made on the basis of the participating experts' feedback as seen in Figure 2. The main change was in CE environment.

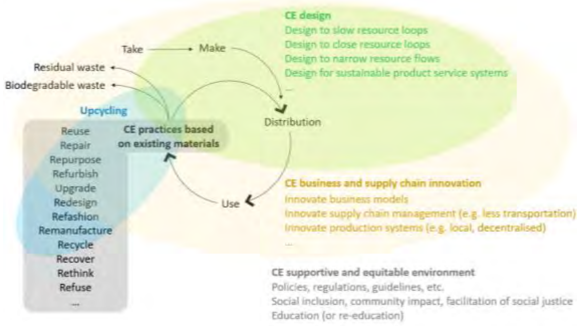

**Figure 2. Upcycling as part of CE revised.**

Regarding the effective ways to communicate the upcycling and CE information for educational purposes, the respondents suggested:
- Demonstration video to talk through the diagram or animated diagram (n=5)
- Visual and written information as training manuals or toolkits in the form of paper, book chapter, poster, etc. (soft and hard copies) (n=2)
- The suggested diagram would work well (n=2)
- Interactive session where learners can give their opinions/ideas
- Hands-on upcycling example activities and competitions
- Research project involving upcycling
- Real-life projects, workshops, seminars
- Symposium or conference
- Exhibitions with thought-provoking images and artefacts
- Breaking down the contents into sub systems (e.g. take, make, distribution, use)
- Focusing on similarities than differences

The respondents' confidence rate was mostly 99-80% confidence in being right (n=10; 66.67%), followed by 79-60% confidence in being right (n=4; 26.67%), and 39-20% confidence in being right (n=1; 6.67%).

## Conclusions
The first phase of Delphi results showed that the participating experts provided diversified and critical comments and feedback on the given descriptions and diagram. There is no consensus made yet which will be achieved throughout the further iterations of the questionnaire with the same expert panel in the future. This is obviously work in progress and hopefully we reach the consensus soon to confirm the contents. Once contents are

confirmed, we will create a short animation video to explain the concepts of upcycling and CE and their interrelationships using the final diagram. Training manual/toolkit will be published as an open access digital document that can be freely downloaded by anyone. We hope that by end of this project we have something substantial to contribute to design education for transitioning towards the circular economy.

## Acknowledgements

This work was supported by the AHRC Research Networking grant for International Upcycling Research Network [grant number AH/W007134/1] and the generous staff innovation allowance from De Montfort University (DMU). The DMU Faculty (Arts, Design and Humanities) Enhancing Research Culture fund also partially supported the conference attendance. We thank Guy Bingham, Stuart Lawson, Kelley Wilder, Kate Cheyne, Siobhan Keenan, Deborah Cartmell and Heather McLaughlin for supporting this research at DMU. Special thanks to Amal Abuzeinab for the inspiration.

# A Multilevel Circular Economy Repair Society Model: Understanding system-wide implications of normalized product repair from the perspective of the Product User

**Sahra Svensson-Hoglund**[(a)], **Jennifer D. Russell**[(a)], **Jessika Luth Richter**[(b)]
a) Virginia Polytechnic Institute & State University, Blacksburg, USA
b) IIIEE, Lund University, Lund, Sweden

**Keywords:** Repair; Circular economy; Consumer behavior; Consumer experience.

**Abstract**: Initiatives to upscale repair activities are becoming increasingly common, with the latest being the EU commission's proposal to strengthen consumers' right to repair. However, these initiatives are not viewed comprehensively, particularly not for how they impact the product user's experience of the repair process, and what type of repair conditions would emerge once fully implemented. This gap exists despite the fundamental need to improve the product user's experience of repair to normalize repair. Repair upscale initiatives must be understood from the perspective of a wider repair system.

In this paper, we introduce a multilevel system model as a tool for capturing the wider repair system for how it impacts the product user; the experience of normalized repair is conceptualized as consisting of various transaction costs, risks and benefits - both in terms of finite resource expenditures, emotional and cognitive responses - what matters for the experience to be overarchingly positive. A two-fold modeling approach is employed; first, we look at the repair systems from a strict resource management perspective (i.e., material, physical flows in the repair process) - the objective reality. Then, on top of this perspective, the "product user experience" of these repair flows is added, capturing the subjective experience and how the solutions to bringing the desired repair flows about can create vastly different conditions for product users.

This model allows for systematic discerning and capturing of the comprehensive implications of higher system level processes for the individual product user.

## Background

### *Understanding Product Users' Experience of Normalized Repair*

Repair activities play a central role in a Circular Economy (CE) and sustainable resource management. For repair to become normalized, users must embrace it and, accordingly, the improvement of the product user's experience of repair must be a priority. The "system of repairability" consists of interconnected factors, ranging from the product's design, decided early in the product life cycle, to social norms, influencing the product user during the use phase (Russell et al., 2022). While policymakers and grassroot organizations are attempting to engage more product users in repair, a comprehensive view of this system, and how it is experienced by the product user - not just what makes someone decide to repair-or-not - is missing.

In essence, to obtain, or rather to regain, the functionality offered by repair, certain costs and risks are inevitable, such as transporting to a site of repair or learning DIY skills. However, there are also potential benefits. These transaction costs, risks and benefits are outside of the control of the individual and must be understood as such. Moreover, they vary significantly depending on the repair system; normalized repair can take many forms, for example through high-tech solutions, conducted solely by professionals behind closed doors, or low-tech practices, conducted at the kitchen table of the product user, or perhaps something in-between (Svensson-Hoglund, Thorslund, et al., 2022). The many possible repair futures can be overwhelming and hinder the formulation of clear goals in today's repair upscale efforts, particularly regarding policy making. To manage this, we propose an approach of "solutions-agnosticism". The goal is to create a tool through which these solutions, and the consequences for how normalized repair unfolds in the future, can be comprehensively assessed - from the perspective of the product user.

As such, we take a multilevel system modeling approach, considering how the product user's experience of repair is the outcome of higher level system conditions (see e.g., Bronfenbrenner, 1977; Akenji & Chen, 2016). This approach entails the identification and organization of variables according to proximity vs. distance to the product user and the depiction of inter-and intra-system level relations between these variables - producing the experience of product user's in said system. However, since a structured multilevel modeling methodology is missing (c.f. Svensson-Hoglund, Thorslund, et al., 2022), we propose a rudimentary such methodology and use it to develop a multilevel system model of a CE Repair Society in which repair is normalized.

The model provides insights to support the formulation of common goals and avoidance of unintended consequences, which in turn can strengthen consumer acceptance, improve industry preparedness and enhance the political legitimacy of the upscale of repair as a societal goal. In this contribution, we further discuss the insights from the model and future research.

## Methodology

Whilst a methodology for developing multilevel models is missing, guidance can be found in systems thinking theories, such as Systems Approach (van Gigch, 1991), Soft System Modeling (Checkland & Poulter, 2006) and Multilevel Analysis (van de Vijver et al., 2008). We divide the modeling into two iterations: (1) capturing repair as an activity within a CE system (i.e., what is happening in the system in terms of material flows and activities)("the Base"), and; (2) translating the activities and physical flows into what they imply for product users' experience of repair ("the Context"). See Table 1.

| | Model Iteration 1 - The Base<br>**The Physical Flows of Repair**<br>Foundations: Industrial Ecology and Circular Economy | Model Iteration 2 - The Context<br>**The Product User Experience of Repair**<br>Foundations: Consumer Studies and Sociology |
|---|---|---|
| | What activities, actors and physical flows are needed for repair to take place? | What does the Product User's Experience consist of? What determines if it is positive or negative? |
| ***1. Conceptualization*** | Conceptualize the Elements of physical flows and activities essential for repair | Conceptualize the Elements of the Repair Experience for Product Users |
| ***2. Review*** | Review of previous models and research on the system of repair | Review of variables in the Experience. |
| ***3. Analysis*** | Code (synthesize) review findings into into nodes and links | Code (synthesize) review findings into into nodes and links |
| ***4. Modeling*** | Use coding results to develop the (graphic) multilevel model iteration | Use coding results to develop the (graphic) multilevel model iteration, built on top of the Foundation |
| ***5. Verification*** | • Check for logic and consistency<br>• State main weaknesses, limitations, omissions and simplifications | • Check for logic and consistency<br>• State main weaknesses, limitations, omissions and simplifications |
| ***6. Final Model*** | Present The Base Model | **Present final model** |

**Table 1. Iterative Multilevel System Modeling Methodology (2 model iterations).**

Importantly, since repair is normalized, the focus of the model is not to capture or predict product user decisions or behavior (see e.g., Jackson, 2005; Blackwell et al., 2006), but rather, what the product users experience of the repair engagement consist of (i.e., with set behaviors).

To scope, we focus on the process of repairing durable consumer products, such as clothing and electronics, not values derived from the product itself (e.g., ascetics or functionality). In a realized CE repair society, all repairs that are financially and environmentally desirable take place. As such, the alternative of replacement is very rare and is not being considered here, although that is an important reference point when considering (relative) value of repair.

## Results

*The Base*

From the perspective of resource management and a product life cycle perspective, a successful repair requires the flows outlined in Figure 1.

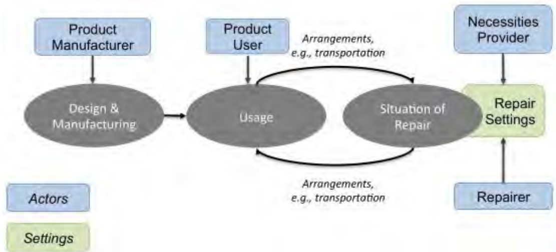

**Figure 1. A Product Lifecycle perspective on Repair (adapted from Russell et al., 2022).**

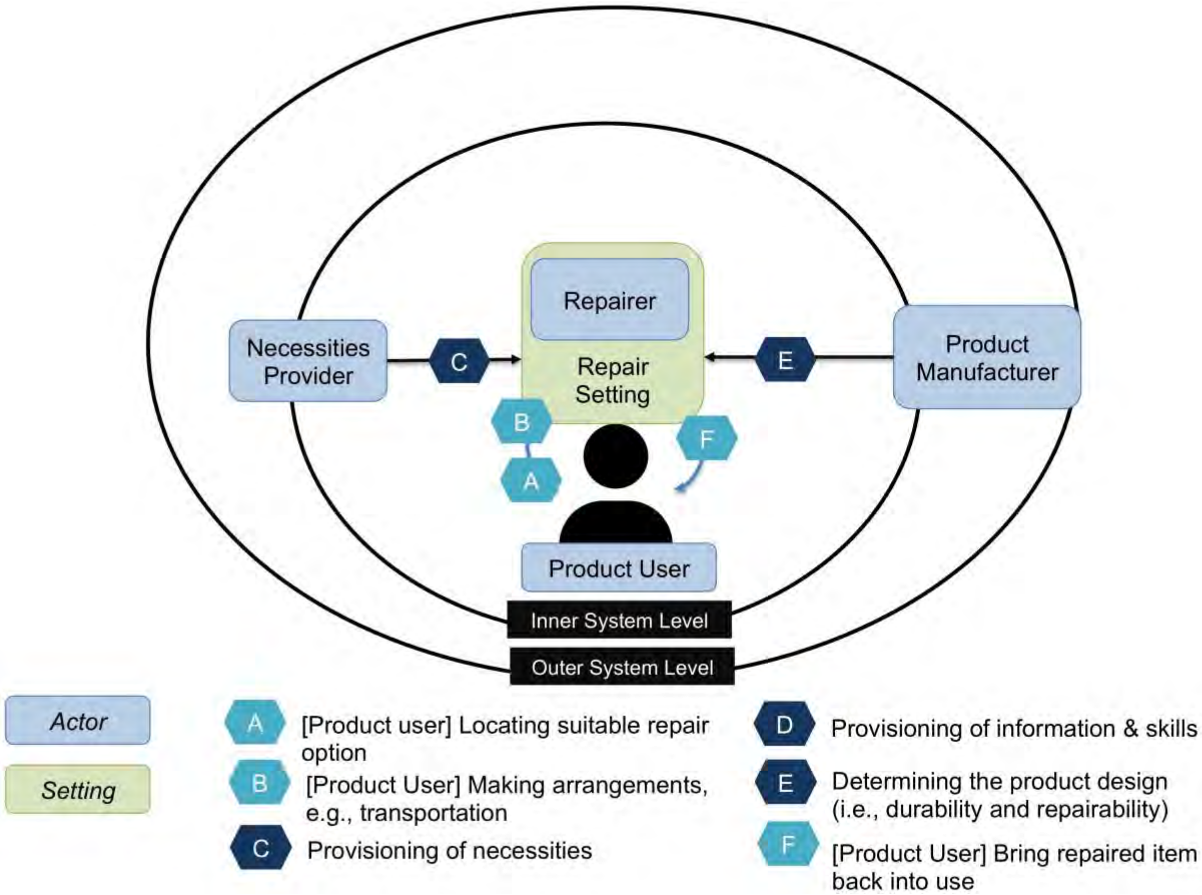

**Figure 2. "The Base" - Actors, Activities and Sites related to the physical flow of the malfunctioning product and necessities in repair, with conditions directly experienced by the product user at the inner system level and those not directly experienced located at the outer system levels (adapted from Russell et al., 2022; Svensson-Hoglund, Russell, et al., 2022)(Model Iteration 1).**

In Figure 2, a multilevel systems view of the material flows, activities and actors in Figure 1 are presented, centered around the Product User.

*The Product User Experience of Repair*

Product user's engagement in repair has been depicted as a multi-stage process (Figure 3).

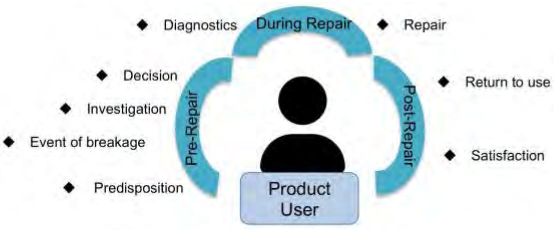

**Figure 3. The Three Stages of the Process of Repair from the Perspective of the Product User (adapted from Svensson-Hoglund, Russell et al., 2022).**

This process inevitably consist of transaction costs, risks and benefits - hereafter referred to as "TCRBs" (see Kahneman & Tversky, 1979), with mediators (i.e., causing the TCRBs) and moderators (i.e., determining the extent of the TCRBs). The combined TCRBs are weighted against each other in the product user's evaluation of the overall engagement, determining whether the experience was predominantly positive or negative (Figure 4).

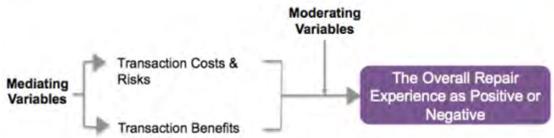

**Figure 4. The Overall Quality of the Product User Experience of Repair (adapted from Svensson-Hoglund, Thorslund, et al., 2022; Svensson-Hoglund, Russell, et al., 2022).**

We focus on the following categories of TCRBs in the process of repair: (1) objective finite resource expenditures (i.e., time, effort and finances) to get something repaired - "actual TCRBs"; (2) emotional or hedonic, such as enjoyment or boredom) - "Experiential TCRBs", and; (3) the value assessment of the entire experience - "perceived TCRBs" - impacted foremost by values (Holbrook & Hirschman,1982).

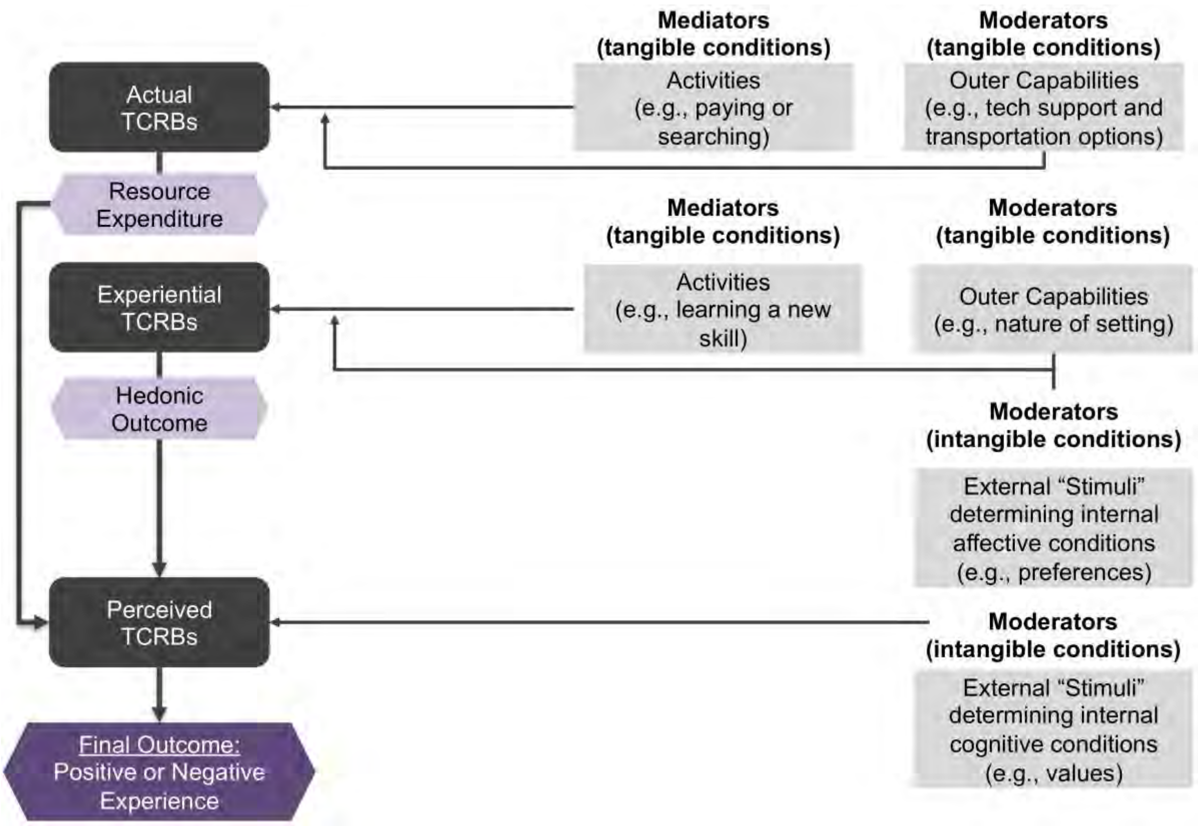

**Figure 5. The Relationship between the three categories of TCRBs (Components of the Repair Experience).**

Among the external conditions, *Actual and Experiential TCRBs* are mediated by the activities needed for repair to take place and moderated by “Outer Capabilities”; e.g., while the availability and quality of repair support impacts the (objective) time and effort it takes to repair something (Actual TCRBs), it can also determine the level of enjoyment vs. frustration (experiential TCRBs)(Kasser, 2017). The *perceived TCRBs* are mediated by both the Actual and Experiential TCRBs, and moderated by intangible conditions, such as socio-cultural influences and other “stimuli”, which - simplified - make up the product user’s predisposition; e.g., environmental predispositions make for a more positive experience of sustainable consumption, despite it being laborious (Binder et al., 2020; Ramos-Hidalgo et al., 2022). These internal conditions are divided into affective (e.g., preferences) and cognitive (e.g., values) conditions (Holbrook & Hirschman, 1982) and provide the assessment criteria for the Interpretation.

In Figure 5, the relationships between the three categories of TCRBs are outlined.

A comprehensive account of the different possible experiential implications of repair engagement is missing in existing research, including broader well-being implications (Svensson-Hoglund, Russell, et al., 2022). Here, we have focused on providing an overview of possible hedonic outcomes (pleasure vs. pain)(Kahneman et al., 1999).

The result of the Review is presented in Table 2 below.

<table>
<tr><th colspan="2">Type of Transaction Costs, Risks and Benefits</th><th>Mediators<br>(adapted from Svensson-Hoglund, Russel et al., 2022)<br>(The action that causes TCRBs)</th><th>Tangible Moderators<br>(External tangible conditions that influence the extent of the TCRBs)</th><th>Intangible Moderators[1]<br>(Non-tangible conditions that influence the extent of TCRBs)</th></tr>

<tr><td>• Waiting time for repair service</td><td>• Operations of repair service (access to necessities and skilled staff)</td></tr>
</table>

[1] Cognitive variables adhere to information processing and center around beliefs or values regarding desirability, while affective elements relate to emotions (Holbrook & Hirschman, 1982). Attitudes (i.e., likes or dislikes) can be both cognitive (i.e., value-based) and affective (i.e., preferential). Particularly the latter is often based on the affective nature of previous experiences (De Houwer et al., 2001), but also social observations and exposure, such as media (Baumeister & Vohs, 2007). As such, we simplify by deriving the internal conditions from the intangible external conditions (see Figure 6).

[2] Due to the scoping on the process, without considering the product, the process of repair incurs only (actual) costs and risk.

| | | | | |

| | | | |
|---|---|---|---|
| | | | • Repairers as trustworthy vs. not (cognitive)<br>• Repair as uncertain/certain outcome (cognitive) Perceived time constraints/availability (cognitive) |
| **Final Interpretation** | | | |

**Table 2. The Transaction Costs, Risks and Benefits (TCRBs), mediating and moderating variables related to the repair process (adapted from Svensson-Hoglund, Russell, et al., 2022; Svensson-Hoglund, Thorslund, et al., 2022; Nazlı, 2021; Lee & Wakefield-Rann, 2021; Lopez Davila et al., 2021).**

From a multilevel perspective, the product user's experience of the system can be characterized by: (1) external conditions (tangible and intangible); (2) internal conditions (determined by external intangible conditions), all of which is subject to; (3) interpretation, or assessment, leading to (4) the final outcome (Figure 6).

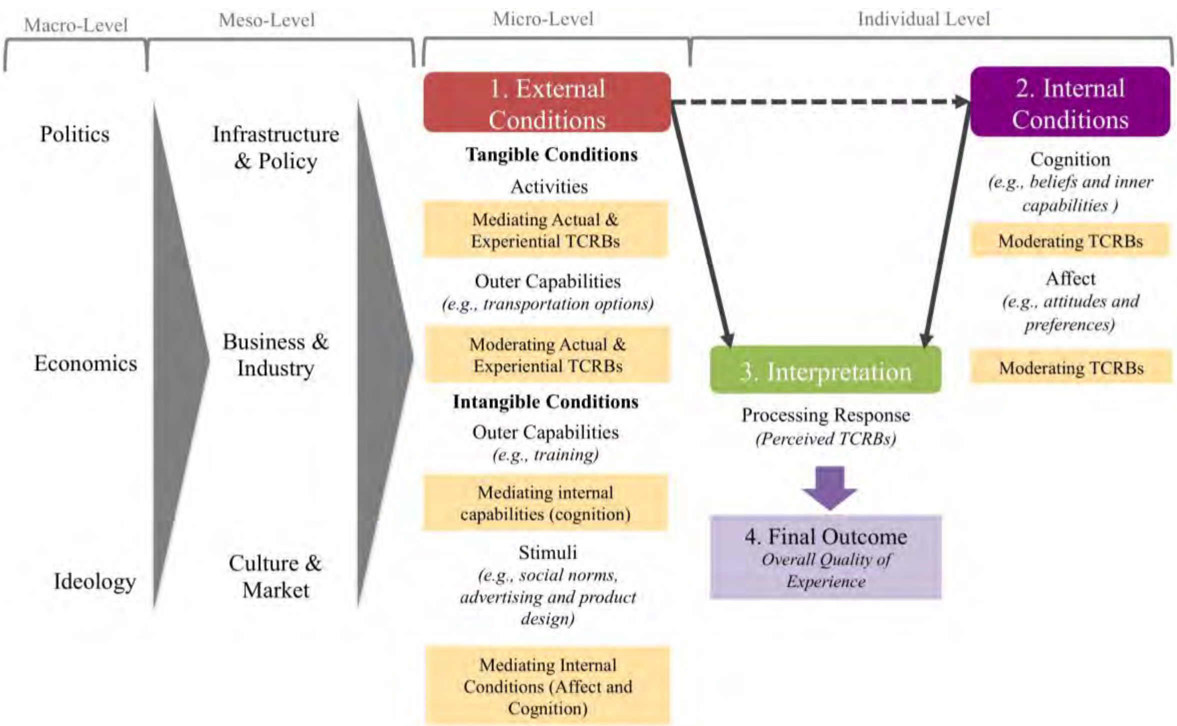

**Figure 6. Categories in The Product User Experience of Repair, taking a Multilevel Systems Perspective. The External Conditions are crucial for the nature of the experience (positive or negative) and is determined by the Macro and Meso system level conditions (adapted from Svensson-Hoglund, Russell, et al., 2022; Holbrook & Hirschman, 1982; Svensson-Hoglund, Thorslund, et al., 2022).**

Following the method presented in Table 1, when the components of the repair experience (see Table 2) and their interactions (see Figure 6) are layered on top of the Base Model (Figure 2), the complexity of the product user's repair experience can be articulated via the Context Model (Figure 7).

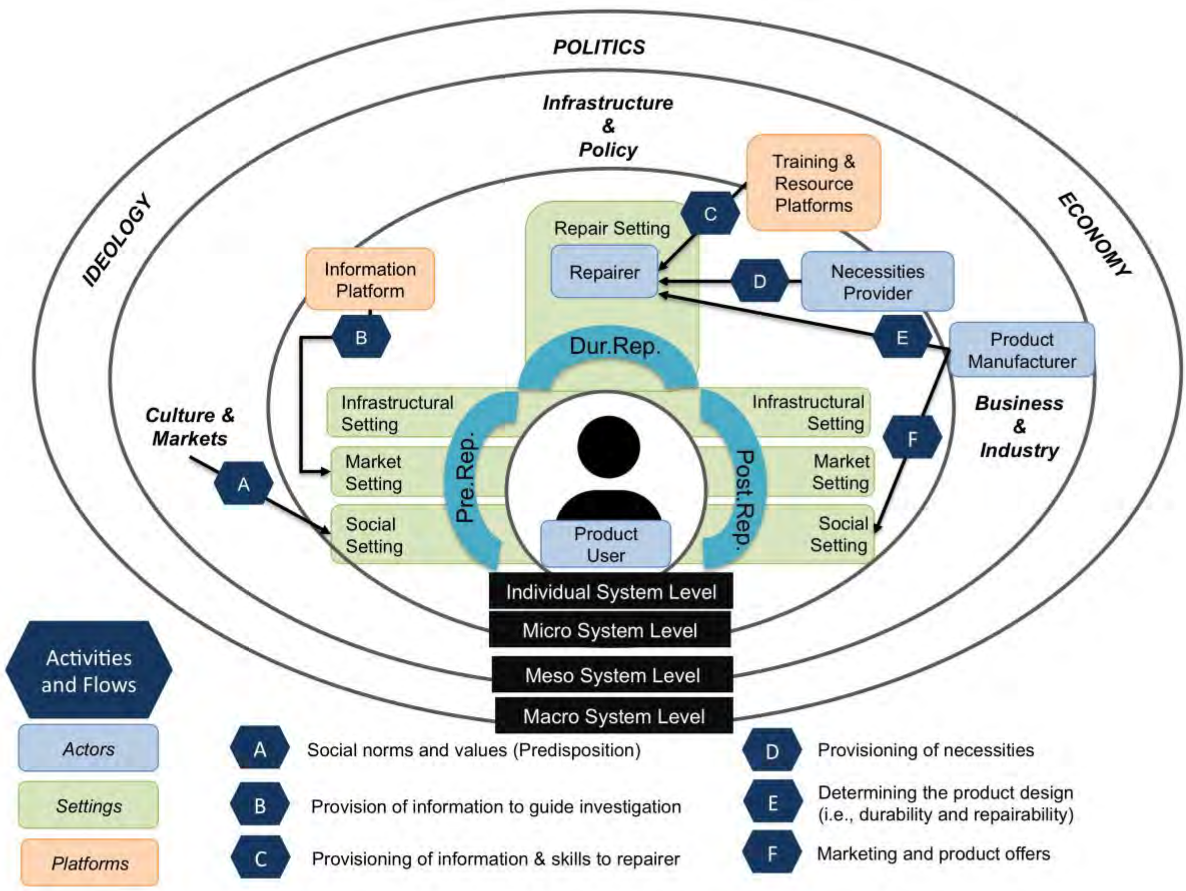

**Figure 7. The Context Model of the Product User's Repair Experience (Model Iteration 2).**

Comparing Table 2 and Figure 7 show that more details need to be considered to identify additional levers or intervention points in the repair system to ensure a positive product user experience of repair.

## Discussion and Concluding Remarks

The analysis presented in this paper suggests that while costs and risks in the repair process may be inevitable, the presence of moderators can mitigate the negative effects. However, benefits of the repair process do not necessarily arise, and are dependent on the presence and nature of the moderators. To ensure that the experience of repair is predominantly positive (i.e., low costs and risk compared to benefits) preferred strategies should seek to simultaneously lower transaction costs and risks, and maximizing the possibility of any benefits that could be obtained, by leveraging both the mediators (i.e., activities) and moderators present within the system. Importantly, trade offs can be seen in some contexts, such as between convenience vs. financial cost (i.e., buying a repair service), and between the level of effort vs. experiential reward (i.e., satisfaction of successfully completing a DIY repair)(Svensson-Hoglund, Thorslund, et al., 2022).

The insights from this conceptual paper brings to the forefront the importance of understanding and addressing the following considerations, as we move forward with the upscale of repair: (1) What are the activities and resource expenditures involved in the repair process?; 2) How can their extent be reduced (i.e., availability of outer capabilities)? Here, who has the right to conduct repair (i.e. repair market governance - see Svensson-Hoglund, 2021) has fundamental implications; 3) How can repair activities be made more enjoyable? This entails identifying relevant activities that can give rise to a hedonic response and their moderators (i.e., "outer capabilities" and internal conditions), and; (4)

How can repair activities be positively perceived? E.g., meaningful or at least an accepted part of product usage.

This paper confirms the importance of not looking at single repair aspects (e.g., price of repair services or access to repair manuals) in isolation (Svensson-Hoglund, Russell, et al., 2022) and contribute insights from a multilevel systems perspective in upscaling repair in order to ensure an overall positive product user experience.

# The Role of Repair as a Resource for Resilience: Case Studies on the Effects of Repair Outcomes of Essential Products

**Sahra Svensson-Hoglund[(a)], Patric C. Nordbeck[(b)], Jessika Luth Richter [(c)], Jennifer D. Russell[(a)]**

a) Virginia Polytechnic Institute & State University, Blacksburg, USA
b) Department of Psychology, Lund University, Sweden
c) IIIEE, Lund University, Lund, Sweden

**Keywords:** Repair; Resilience; Financial accessibility; EEE.

**Abstract**: In both the US and EU, policymakers and government agencies are acknowledging the importance of having access to repair options, particularly for vulnerable product users who depend on their products. As such, repair can play an important role as a resource for resilience, but research is missing. We propose that repair can act as a resource for resilience. A comprehensive, structured way to understand this role of repair is needed to: (1) show how repair is a social interest and thereby increase public willingness to overcome current barriers to repair, and; (2) ensure that current policy efforts to increase access to repair succeed at strengthening the resilience of product users.

To test this framing, we use four case studies on the breakdown of essential products; laptops in schools, tractors at farms; cell phones in refugee camps, and ventilators at hospitals. Our findings indicate that the conditions under which repair can function as a resource for resilience can be regarded as a span: on one end repair is crucial for continued functioning, due to the lack of other options in the pre-breakage context; on the other end, repair constitutes, compared to other available options, the most beneficial strategy for restoring functionality. Further, the effectiveness of repair as a resource for resilience is determined by the conditions of repair as high vs. low friction. Moreover, we find that while repair constitutes, in itself, a resource for resilience, it also has the potential to act as a gateway to other resources for resilience, such as financial and social. Implications for policy and future research are briefly discussed.

## Introduction

Repair is often promoted for benefits including prolonging product lifetimes and functionality, lowering the total cost of ownership (compared to having to buy a replacement product; Brusselaers et al., 2019; DeBellis & Proctor 2021) and reducing environmental impacts (IRP, 2018). Repair also encourages local economic investments by creating jobs (Riisgaard et al., 2017; EC et al., 2018) and community organizations (e.g., repair cafes) that serve to enhance community building and inclusion (Wackman & Knight 2020). Repair can also be a resource for resilience, i.e., the process in which individuals or entities draw on resources to manage disruptions, such as a disaster or unemployment (Do et al., 2022).

The importance of having access to repair options, particularly for those who are dependent on their products, is acknowledged by both US and EU policymakers and government agencies (see e.g., FTC, 2021); they are striving to overcome current repair restrictions, such as lack of repairability in the product design and lacking access to spare parts (U.S. Federal Trade Commission, 2021; Svensson-Hoglund et al., 2021). However, research on the role that repair plays in the resilience of individuals, communities, businesses and society at large, is missing.

A comprehensive, structured way to understand this role of repair is needed to: (1) show how repair is a social interest and thereby increase public willingness to overcome current barriers to repair, and; (2) ensure that current policy efforts to increase access to repair succeed at strengthening the resilience of product users. In this paper, we use case studies to develop a conceptual framework for considering the role of repair as a resource for resilience.

### *Resilience & Repair*

Although resilience is defined differently across disciplines (see e.g., Olsson et al., 2015), this work adopts the conception of resilience as the capacity to maintain or regain function lost due to some kind of disruption. Here, resilience is regarded as a two-dimensional construct with: (1) exposure to disruption, followed by; (2) a positive adjustment (Luthar & Cicchetti 2000), meaning a return to, or the maintenance of, a similar function. In the context of repair, it is important also to note here that “function” is in part a relational term, meaning that it depends on the relation between the product and the User. For example, if the main purpose of a tractor is the farmer’s entertainment, then losing functionality of the tractor will not likely have any bearing on the farmer’s resilience. However, if the functional relation between tractor and farmer is livelihood, then reliance on the product becomes *essential*.

Previous research on repair and resilience focuses on the effects of disruptions directly to the system of repair, such as repair shops being closed down during the pandemic and spare parts supply interrupted, pointing at the importance of distributed repair capacity (vs. centralized to few providers) (Salvia & Prendeville, 2017; Svensson-Hoglund, Thorslund, et al., 2022). Studies exploring access to repair, and effects on resilience, are limited to topics of access to low-cost refurbished devices to bridge the digital divide (Gonzales et al., 2022). The conditions that make repair important for resilience are missing.

### *A Process Framework for Thinking of Repair as a Resource for Resilience*

Resilience is an emergent property of a process (Nordbeck, in prep), observable in the maintenance of a system’s functioning. In the context of repair, this process can be summarized in two distinct stages, Pre-Repair and During- and Post-Repair (Figure 1).

A product breakdown is handled in one of three ways: by obtaining a replacement, doing without, or repairing the broken item (Figure 1; Russell et al., 2022).

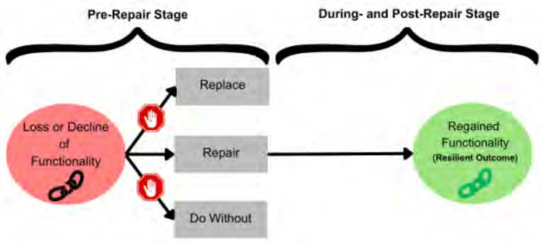

**Figure 1. The two stages of the repair process (adapted from Russell et al., 2021).**

For essential products, making adjustments to *do without* them might not lead to regained functionality, hence it does not lead to a resilient outcome (Figure 1). Alternatively, the *replacement* of a product may not be a timely, financially or physically available option. For example, the COVID-19 pandemic showed how access to new products cannot always be relied upon (Hynes et al., 2020); stores were shut down, and global supply chain disruptions, coupled with rise in demand led to product shortages. In addition, particularly during the pandemic, many people were cut off from their livelihoods, making replacements unaffordable. Hence, in these instances when doing without and replacing are not possible or suitable responses to regaining functionality, the ability to *repair* is more critical than ever (Figure 1).

In the context of essential products, disruptions are defined as a disturbance to the user and/or product system, which risks compromising its current working state. A product breakdown does in itself constitute a particularly destructive disruption to the product system. Regarding essential product breakdowns, there is a risk of system failure. In these situations, lack of resources (or barriers to drawing on a particular resource) that increase the exposure to said risks constitute a so-called “vulnerability”. While a disruption has the potential to disturb any (otherwise well-functioning) system, the presence of a vulnerability increases the probability of system interruption as a result of the disruption. However, the effects of a disruption on system functionality (e.g., the hospital or farm) are determined during the process within which the disruption happens. There may be other mitigating factors, or other resources to draw on to cope with the situation that allows for somewhat retained functionality (Nordbeck et al., in prep).

In order to conceptualize the role of repair in resilience, greater understanding of two sets of conditions is crucial (Figure 1). First, the conditions at the time of an essential product breakage, *pre-repair*, i.e., the types of risks, disruptions and vulnerabilities related to repair. Second, the conditions present *during- and post-repair*, which can determine the nature of, and the extent to which, system functionality is preserved through the repair, and the degree to which repair is hindered vs. facilitated. We focus on the level of transaction costs to the individual or entity's finite resources (i.e., temporal, financial, and cognitive), as well as the benefits of avoiding replacement (Brusselaers et al., 2019) (Figure 1).

Importantly, there are several different forms of repairs; so-called "authorized" repair conducted by the product manufacturer and their network, and so-called independent repairers, unaffiliated with the manufacturer, Then, there are non-commercial repairs (i.e., DIY or community repair). This distinction is important, as the "right to repair" involves who should be able to perform repairs (i.e., which forms of repairs that are made available)(FTC 2021; Svensson-Hoglund et al., 2021).

## Methodology

Using case studies of the breakdown of essential products (laptop used for education, cell-phones used by refugees, appliance in a family household, tractor at a farm, and ventilator at a hospital), we explored the two sets of conditions at the Pre-Repair and During- and Post-repair respectively and assessed how, and under what conditions, repair enables resilient outcomes. The cases were collected from news reporting, and mini-documentaries found using the search terms "repair" and "hindered" on Google and were selected due to the focus on a specific individual or entity. Purposeful sampling was based on: (1) the product being essential; and (2) there being enough details available regarding the conditions of the process (Patton, 2002). To narrow the scope of data collection, the data gathered on the case studies focused on the two sets of conditions in the process of regaining functionality (Figure 1).

In the discussion, we use the results to create a conceptual framework of the role of repair as a resource for resilience, and discuss implications for repair policies and future research.

## Result & Analysis

The conditions at the two stages of the repair process from four case studies on repair are outlined in Table 1.

## Discussion and Concluding Remarks

### *When Repair Constitute A Resource for Resilience*

The case studies show that *conditions at pre-repair* have two effects. Firstly, they make doing without the product much more costly to the overall functioning of the product system because the disruption increases product dependance; e.g., the COVID pandemic (i.e., a disruption) increased the need for ventilators for the hospital system to function. Second, disruptions can also hinder access to replacements, e.g., a surge in demand and/or (additional) disruptions to the supply chain. As such, increased societal product dependance breeds more such dependence, and thereby heightens the probability of system failures. This creates repair-dependace.

The *conditions present during- and post-repair* have two effects: the repair inevitably incur a cost to the limited resources of the individual, but can also produce gains - all at varying degrees, depending on the specific conditions.

When repair constitutes the only option (pre-repair), i.e., high repair dependance, any adverse condition present at the during- and post-repair stage poses a greater risk since, if repair is hindered, the product system will not retain its functioning and risks may be realized. Importantly, even when repair is not the only option, it might still constitute the most beneficial, resilience-enhancing option; e.g., using savings to buy a new tractor or laptop vs. maintaining a financial buffer.

Thus, the role that repair can play as a resource for resilience can be regarded as a span (Figure 2): on one end, repair is crucial for continued functioning, due to the lack of other options determined by the pre-repair conditions (*high risk*); on the other end of the span, repair is the most beneficial strategy, amongst many (*lower risk*, at least in the short-term) (Figure 2).

| | ***Disruption Occurs**** (to product system or user) | ***Functionality Lost in Case of Breakdown*** (***the Risk***) | ***Vulnerability*** to the risks with product breakdown | ***Constraints in the Conditions of the Repair Process*** |
|---|---|---|---|---|

[4] Scher (2020); Paul (2021)

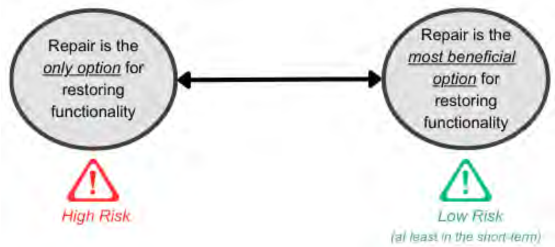

**Figure 2. The conditions under which repair constitute a resource in resilience, seen as a span between repair constituting the only option for restoring functionality vs. the most beneficial.**

Disruptions to product systems, such as supply chain issues, pandemics and even war are inevitable, particularly in today's connected world, and can cause increased product and repair dependance. Although repair restrictions hit individuals with vulnerabilities (e.g., unemployment or disabilities) the hardest, those without vulnerabilities can have their resilience weakened (i.e., finite resources drained) by repair restrictions. Hence, the role of repair in the resilience of individuals is that "repairability" impacts short-term/immediate disaster management *and* builds more long-term capacity to manage future crises. This shows that it is not only essential products that are relevant to consider, but all types of products that the user wants to keep functional.

Repair is in itself a resource (i.e., direct) for resilience (e.g., ventilator working and thereby saving lives). Also, it can act as a gateway (i.e., indirect) to both perveserving and accessing other resources for resilience; if repair is widely accessible, the financial resources of the individual are preserved. Additional resources that repair can (indirectly) provide access to are, e.g., providing an otherwise isolated individual with social connection and inclusion through their attendance of community repair cafés (Wackman & Knight 2020). Moreover, gaining repair skills can also fulfill psychological needs, such as a need for competency (Kasser 2017), benefiting emotional resilience.

### *What Determines the Efficiency of Repair as a Resource for Resilience*

These case studies highlight that, regardless of differences in individual and contextual conditions, the factors enabling or impeding repair are similar. In essence, they adhere to the financial, physical (e.g., within travel distance), and timely availability of the repair option, and its quality. To this point, the repairability conditions in the during-and post-repair stage can be regarded as a span (Figure 3); ranging from repair options existing (but at a high transaction costs) vs. access being optimized (at a low cost) and offered at a good enough quality.

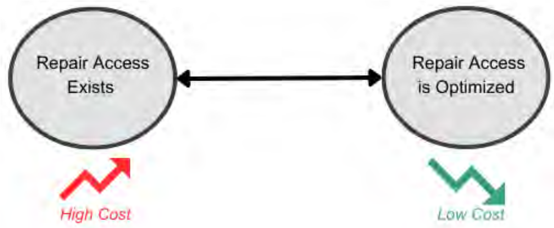

**Figure 3. The level of access to repair as determining the effectiveness of repair as a resource for resilience, seen as a span between high-transaction cost access vs. optimized, low transaction cost access.**

### *Implications and Future Research*

Product- and repair-dependance can arise for many different reasons (i.e., disruptions and/or vulnerabilities). The capacity for repair to act as a resource for resilience is determined by the conditions in the repair process. Repair is, in itself, a resource (i.e., direct) for resilience (e.g., ventilator working and thereby saving lives). Also, repair can act as a gateway (i.e., indirect) to perveserving, as well as accessing, other resources for resilience, such as financial, social and emotional resilience. More research in this role of repair is needed.

Eliminating barriers to repair can be seen as part of efforts to build more resilient communities, cities and societies and there are many policy suggestions to remove fundamental barriers (see e.g. Svensson et al., 2021). At the same time, repair can be supported by local, national and international initiatives. Considering Figure 3 on the level of access to repair, bringing about "optimized access" to repair entails a balance between affordable and accessible repair vs. ensuring repair quality and providing assurances needed for a resilient outcome. Moreover, repair capacity must also be distributed across society so as to minimize the effects of disruptions and vulnerabilities to the system of repair itself (vs. directly to the product system, which has been the focus of this paper), such as repair shops being closed down during the pandemic and spare parts being unavailable (Salvia & Prendeville, 2017; Svensson-Hoglund, Thorslund, et al., 2022). Building resilience through diversity constitutes one out of five principles of a CE (EMF 2013).

Emphasis on efficiency over resilience leads to “brittleness”; the fewer nodes in a system, the more vulnerable it is to failure, while a resilient system consists of many nodes that make it possible to recover from disruptions; “Diversity is like a storehouse of possibilities to which change adds or subtracts. Without such a storehouse of diversity, ‘change’ would more often be fundamentally destructive” (Webster 2013 p. 550). As such, “optimization” rests between efficiency for change and resilience for continuity (Webster 2013).

# Cutting the life of reusable products short: Understanding overconsumption behaviour for refill at home FMCGs

**Catriona Tassell**[a]**, Marco Aurisicchio**[a]
a) Dyson School of Design Engineering, Imperial College London, London, United Kingdom City

**Keywords**: Overconsumption; Replacement; Consumer Behaviour; Reuse; Fast Moving Consumer Goods.

**Abstract**: Context and problem: The fast-moving consumer goods market is flooded with single-use products. Once used for a short amount of time, some of the materials are recycled but many are sent to landfill. Reusable alternatives offer the potential to slow the speed of consumption and reduce waste. However, this potential is compromised if these products are overconsumed. Aim and method: Through conducting 13 in-depth interviews, this study explores what influences consumers to own multiple reusable products or to replace them with new ones before the intended end of life. In total 18 product cases were studied covering razors, toothbrushes, bottles and cups. Results: Emerging from the interviews, 32 factors influencing overconsumption were identified and categorised according to constructs included in the Fogg's behaviour model, namely motivation, ability, and prompt. The factors were found to emerge in either the purchase, use or disposal stages of the consumer journey. For example, during purchase consumers decided to acquire reusables as they wanted to experience new products, during use as they were influenced by unsatisfactory product experiences, and during disposal as they felt that products had been used for long enough though they still worked. Conclusions and implications: The factors identified indicate why the potential for reuse to reduce impact may be compromised. In its current state, reuse seems to continue to fuel overconsumption rather than addressing the top goal of reduction in a circular economy. The factors can be used to deploy interventions that encourage continued reuse and prevent the overconsumption of reusables.

## Introduction

Fast moving consumer goods (FMCGs) are framed by a culture of convenience and disposability, where consumers buy and use products on-the-spot to satisfy their needs before throwing them away. Reuse is a strategy capable of extending the utility of materials and slowing down consumption in comparison to single-use. In the waste hierarchy and circular economy frameworks it sits above recycling (The Ellen McCarthur Foundation, 2013; UK Government, 2011). Repeated use of reusable products is critical to offset their environmental impact in comparison to single-use (Changwichan & Gheewala, 2020; Muranko et al., 2021). However, in refill at home offerings, where consumers are responsible for refilling reusable products in their own environment (Ellen MacArthur Foundation, 2019), consumers determine the number of reuse cycles and lifetime of products. If reuse is not practiced as intended, circular rebound effects may occur with unintended consequences that undermine sustainability (Bradley & Corsini, 2023). Therefore, the aim of this research is to understand the factors across the purchase, use and disposal stages that play a role in influencing overconsumption (i.e. owning multiples and replacing) of refill at home FMCGs.

## Factors influencing FMCG reuse consumption

There is a small but growing body of research on FMCG reuse which has highlighted several motivational and contextual factors that either facilitate or act as barriers to consumer engagement, see Table 1. Several interventions have also been tested, listed as 'prompts' in Table 1.

| Type | Influence | References |
|---|---|---|
| **Motivation** | Barrier: Uncertainty about the potential for impact reduction | (Kunamaneni et al., 2019) |
| | Barrier: Low quality products<br>Facilitator: High quality products | (Choate et al., 2014; Lofthouse et al., 2009) |
| | Barrier: Concerns over safety | (Choate et al., 2014) |
| | Facilitator: Sense of place/ collective identity | (Vaughan et al., 2007) |
| | Barrier: Fear around cleanliness and hygiene | (Lofthouse et al., 2009) |
| **Ability** | Barrier: Inconvenience (e.g. slow, difficult)<br>Facilitator: Convenience (e.g. quick, easy, hassle-free) | (Choate et al., 2014; Lofthouse et al., 2009) |
| | Facilitator: Light to transport<br>Barrier: Heavy to transport | (Lofthouse et al., 2009) |
| | Barrier: Desire to reduce cognitive effort when shopping | (Kunamaneni et al., 2019) |
| | Barrier: High price<br>Facilitator: Low price | (Bashir et al., 2020; Lofthouse et al., 2009) |
| | Barrier: Lack of availability<br>Facilitator: Availability | (Ertz et al., 2017) |
| **Prompt** | Facilitator: Environmental messaging | (Bashir et al., 2020; Poortinga & Whitaker, 2018) |
| | Facilitator: Provision of information | (Miller et al., 2011) |
| | Facilitator: Charging extra for disposable alternatives | (Poortinga & Whitaker, 2018) |
| | Facilitator: Provision of reusable products | (Poortinga & Whitaker, 2018) |

**Table 1. Factors influencing reuse behaviour classified under the constructs of Fogg's behaviour model.**

However, there remains a focus on specific FMCG categories or products, such as cups (Poortinga & Whitaker, 2018), and moments of the consumer journey, such as pre-purchase (Bashir et al., 2020; Kunamaneni et al., 2019; Miller et al., 2011). Furthermore, previous research is focussed on how to increase consumer transition to reusable products, assuming that intended reuse behaviour will occur and help to reduce environmental impact. There is a gap in understanding behaviour across the journey for different products and the types of FMCG reuse that threaten impact reduction potential.

## Methodology

### Conducting interviews

Focussing on the overconsumption of refill at home FMCGs, 13 interviews (7 males, 6 females) were conducted covering 18 cases (razors: 7, toothbrushes: 4, bottles: 4, cups: 3). Participants were guided to discuss their practices for each case across purchase, use and disposal. Each interview covered one or two cases.

Based on the three constructs in Fogg's (2009) behaviour model, participants were asked to discuss why they wanted to carry out each behaviour (motivation), what made it easy for them to do it (ability) and whether there were any additional triggers that cued them (prompts).

### Analysing the data

The six stages outlined by Braun & Clarke (2006) were used to carry out a thematic analysis. Once transcribed, the interview data were systematically broken down into 124 chunks and coded with a brief description of the factors influencing overconsumption using NVivo (release 1.5.1). Then, using Fogg's (2009) pre-defined constructs and themes (e.g. *motivation – anticipation*: *hope*, see the first line in Table 2) as a deductive starting point, the chunks was categorised accordingly (see full breakdown of Fogg's constructs and themes in Table 2).

The grouped chunks were re-read in the context of each Fogg 'theme', confirming or revising the placement. Within each Fogg construct and theme, the chunks were compared and grouped by similarity, and the summary descriptions for each of the chunks synthesised, leading to 32 sub-themes, which are factors influencing ownership of multiple reusable products or replacement. Whilst some of Fogg's themes were not identified in the data (shown in grey, Table 2), a new theme termed *access* was introduced (also included in Table 2). Conversations with a more senior researcher during each stage helped to identify, develop, and establish key sub-themes.

| Construct | Theme |
|---|---|
| Motivation | Anticipation: Hope |
| | Anticipation: Fear |
| | Sensation: Pleasure |
| | Sensation: Pain |
| | Belonging: Social acceptance |
| | Belonging: Social rejection |
| Ability | Access* |
| | Money |
| | Physical effort |
| | Time |
| | Routine |
| | Mental effort |
| | Train |
| | Tool/ resource |
| Prompt | Spark (increase motivation) |
| | Facilitator (increase ability) |
| | Signal (reminder) |

**Table 2. Breakdown of Fogg's constructs and themes.**

## Results

In total, 32 factors were identified influencing overconsumption of refill at home FMCGs through ownership of multiple products or frequent replacement. In Table 3 these are grouped according to Fogg's constructs and themes (e.g. *motivation – anticipation: hope*), and are situated across the consumer journey, with 17 in the purchase stage, 11 in use and four in disposal. Motivation and ability factors are further described below.

## Purchase

### *Motivation*

*Anticipation: Hope.* Participants' felt that buying another reusable product would lead to them owning a product that was (1) better quality, (2) better for the environment and (3) better for their personal needs. In seeking better quality, participants discussed wanting a more durable product, even at the expense of paying a higher price. Additional purchases were believed to reduce environmental impact, especially through the use of more sustainable materials (e.g. moving away from razors made of virgin plastic to those made from recycled plastic, bamboo or recyclable metal). Further still, participants suggested that buying from a new company committed to minimising environmental impact could be used as a form of protest against big corporations, withdrawing support and pressuring them to change. Despite occurring less frequently, personal needs also prompted replacement when participants hoped that an alternative reusable product would be better for them (e.g. a razor for sensitive skin).

*Sensation: Pleasure.* Participants were drawn to buy another reusable product due to (4) its aesthetic qualities, (5) wanting to try a new item and (6) intending to reduce their footprint. Design was influential in product replacement (e.g. bottles) and the enjoyment of experiencing something new (e.g. razors). These kinds of pleasure-seeking desires were often at the expense of environmental impact. For a smaller number of participants, it was precisely the positive feelings related to behaving more sustainably that influenced replacement.

### *Ability*

*Access.* Participants were influenced to buy another reusable product, both when their access to replenishable components (e.g. razor blade cartridges) reduced due to them (7) being discontinued or no longer stocked and, more frequently, when their access to different options increased due to the (8) extensive range of other choices available. It was very common for participants to overconsume due to (9) being given products free of charge. This occurred at events, where gifts are offered as a marketing strategy.

*Money.* Sometimes participants made (10) price comparisons, finding a cheaper reusable product to replace their current one whilst, in other cases, it was simply (11) affordable to buy more than necessary. Prices were compared for replenishable components (e.g. razor heads), both on the spot and through the consideration of savings over time.

*Routine.* There were instances where (12) habitual behaviour overtook more meaningful decision-making during purchase, buying impulsively without thinking or out of convenience.

## Use

### *Motivation*

*Anticipation: Fear.* Participants purchased a new reusable product as they reported feeling worried that their product might (18) cause

| Stage of the journey | | Purchase | Use | Disposal |
|---|---|---|---|---|
| **Fogg construct** | **Fogg theme** | **Data code** | | |
| **Motivation** | **Anticipation: Hope** | (1) Found a better-quality product<br>(2) Found a product better for the environment<br>(3) Found a product better for personal needs | | |
| | **Anticipation: Fear** | | (18) Worried the product would cause injury<br>(19) Worried the product presented a danger to health<br>(20) Worried about environ. impact of the product | (29) Worried about the environ. impact of landfill |
| | **Sensation: Pleasure** | (4) Liked the design of another product<br>(5) Wanted to try another product<br>(6) Felt good about the product lowering impact | (21) Liked the product enough to buy more | |
| | **Sensation: Pain** | | (22) Had a negative product experience<br>(23) Found the product experience reduced over time<br>(24) Found the product became dirty and unhygienic | (30) Had a component or product that broke |
| **Ability** | **Access** | (7) Could not find certain components<br>(8) Had many options to choose from<br>(9) Received new product as a freebie or gift | (25) Kept multiple as back up but don't use them<br>(26) Lost/ forgot components or whole product | |
| | **Money** | (10) Found another cheaper product<br>(11) Could afford to buy more | | |
| | **Physical Effort** | | (27) Found the product impractical to use | (31) Recycling components was too much effort |
| | **Time** | | | (32) Felt like it had been used for long enough |
| | **Routine** | (12) Did not think when buying | (28) Use different products for different contexts | |
| **Prompt** | **Spark** | (13) Was exposed to advertising<br>(14) Saw packaging in store<br>(15) Looked at the sales statistics | | |
| | **Facilitator** | (16) Responded to special offers<br>(17) Ran out of consumable | | |

**Table 3. Factors influencing the overconsumption of FMCGs across the consumer journey.**

injury to the body and be (19) a danger to their health or (20) the environment.

Plastic components and batteries were viewed as unsustainable, with plastic also considered a health risk due to possible chemical ingestion (e.g. drinking water from an old plastic bottle). Though less frequently identified, certain more niche products (e.g. cut throat razor) were highlighted as particularly risky, requiring additional skill, thus influencing the decision to own other reusable razors for daily use.

*Sensation: Pleasure.* There were instances when participants (21) liked the experience of a reusable product enough to buy and own more than one.

*Sensation: Pain.* However, it was more common to replace reusable products due to the (22) product experience not being good enough, more specifically when the experience (23) reduced over time, or the product (24) became dirty and unhygienic. Here, participants spoke about products getting old and less effective (e.g. toothbrushes), and wearing and breaking (e.g. bottle tops), or becoming difficult to clean (e.g. bottles).

### *Ability*

*Access.* Participants either had extra access to reusable products through (25) keeping multiple or reduced access through (26) loosing components or products, prompting their replacement. Further, participants were reluctant to dispose of reusable products, even when they no longer used them, suggesting a sense of comfort in having extra products as back-up. Others replaced reusable products when they forgot to take them somewhere with them (e.g. razor) or lost components (e.g. bottle tops) and products (e.g. bottles). Having multiple hot drinks cups also proved useful in situations where one got temporarily misplaced. *Physical effort.* In addition to the cut throat razor presenting a risk of injury it also required more effort and was therefore (27) impractical.

*Routine.* Similarly to having back-up products, there were situations where, for convenience, participants (28) owned multiples but actively used them all, reserving each for a different context (e.g. permanently storing a razor in a travel bag or using a hot drinks cup for home and another for work).

## Disposal

### Motivation

*Anticipation: Fear.* Despite being less frequent, (29) environmental impact was a factor even in this stage of the journey. Fear stems from product components going to landfill, leading participants to seek alternative razors with better end of life outcomes.

*Sensation: Pain.* Pain continues to evolve around product experiences, going beyond merely being unsatisfactory or reducing in quality over time and resulting in (30) components or products being broken and reaching the end of life. This is particularly problematic when parts are not replaceable, such as when bottle tops are broken but the whole bottle requires replacing.

### Ability

*Physical effort.* Physical effort presented itself through the (31) additional steps required to replace and recycle some components. Again, batteries were discussed.

*Time.* Time was used as an indicator of length of life (32) regardless of the product condition. This was closely associated with the price of repurchase (see Section 4.1.2 *Money*), whereby participants associated the price of the product with a length of time that felt as sufficient value had been obtained.

## Discussion, further research and conclusions

The results of this study offer new understanding of reuse through highlighting the extensive range of factors that can influence consumers to *over*consume refill at home FMCGs.

Most factors emerged during the purchase stage, where participants showed high levels of *motivation* and *ability* to buy multiple or replace refill at home FMCGs. In this stage, participants experienced positive *motivation* through *hope* and *pleasure.* Factors can be traced to the *environment*, the *product* and the *self*. Exposure to various sales and marketing techniques also *prompted* participants to overconsume during purchase. Interestingly, the need to replenish the consumables in reusables (e.g. running out of blade cartridges for a razor handle) was found to cue repurchase of reusables rather than replenishment of consumables. This somewhat mirrors the consumption of single-use disposables, calling for new sales strategies and prompts that reinforce reuse rather than repurchase. The absence of factors relating to *fear*, *pain*, *physical effort* and *time* reinforce the notion that the purchase experience is overtly positive, in line with research suggesting that shopping is fun and pleasure driven (Babin et al., 1994). Notably, during purchase, the only reason for acquiring a new product triggered by the loss of functionality and usability of a previously owned product is the fact that spare components were no longer available. This suggests that, in most cases, a functioning product is used in parallel with the new purchase or replaced.

Regarding the factors that emerged during the use and disposal stages, whilst some participants purchased multiple products due to the *pleasure* they experienced in using them, most factors indicate a low level of *motivation* to continue using previously owned products through *fear* and *pain.* Factors can once again be traced to the *environment*, the *product* and the *self*. There are instances where having multiple products increased *ability* through *access* to back-up, and where assigning products to different contexts enables routines to be formed. However, low *ability* permeates the use and disposal stages, where loosing products reduces *access*, high *physical effort* prevents the desire to repeat behaviours, and the length of *time* a product is owned dictates the end of life rather than product wear. In these stages, there are more frequently identified reasons for overconsumption related to loss of functionality and usability of previously owned products. However, once again, these do not outweigh other reasons suggesting that a functioning product is often going to be used in parallel or replaced. Therefore, it is necessary to encourage consumers to continue using functioning products or, at very least, to implement more take-back schemes that maintain and redistribute these products effectively.

It is interesting to address the relationship between the factors identified in this study to influence the *over*consumption of refill at home FMCGs, and the factors found in previous research to engage consumers in the transition to buying these products. Whilst bad quality products and price (Lofthouse et al., 2009) can prevent consumers from buying reusables in the first instance, once purchased, these factors can also influence replacement. Furthermore, environmental messaging can increase the likelihood that consumers buy reusable hot drinks cups over disposable cups (Poortinga & Whitaker, 2018) or that consumers consider a home cleaning refill service (Bashir et al., 2020) but, ironically, products marketed as more sustainable can also influence consumers to replace already owned reusables. This suggests that, as 'more sustainable' reusable FMCGs enter the market, consumers will continue to prematurely replace products they already own in the quest to be better. Whilst still encouraging consumers to shift away from disposables, new mechanisms are required to ensure that this does not then replicate the current system of overconsumption that exists for single-use. Lifecycle analyses could help quantify instances when continued reuse of 'less sustainable' products is less or more impactful than replacement with 'more sustainable' ones.

# Flawed or redundant: products with long lifespans against the odds

**H. Throne-Holst[(a)] & K. Laitala[(a)]**
a) SIFO - Consumption Research Norway, Oslo Metropolitan University, Norway

**Keywords**: Consumer dissatisfaction; Faulty products; Inactive products; Lingering value; Divestment.

**Abstract**: Many strategies are proposed that should enable the consumers to keep using the products for longer, but there is less research on which and how consumer practices contribute to longer lifespans. In this paper we focus on two specific, distinct ways of reaching long lifespans: 1) retaining redundant products even though they are not needed or used, and 2) keeping on using flawed products despite they no longer functioning, fitting, or delivering the expected service level. In the former, the products are passive while in the latter they remain in active use and thus reach longer service life. The discussion is based on six focus groups conducted in connection with the project LASTING. The overarching theme was product longevity of three product groups: electronics, textiles, and furniture. Our analysis points to five categories of explanations for products that are either kept despite the lack of any intention of using them again or retained in active use despite flaws: Economical, Ethical, Social, Emotional, and Intentions. It remains important to focus on active service life and various ways to promote it to reduce the environmental and climate impacts of consumption. The role of each of the five categories will be discussed, as well as implications for sustainability and policy options.

## Introduction

The timing of product disposal is an important aspect of circular economy, where the value of products should be kept at highest level for longest possible time, thus using and reusing products as they are, before recycling the materials.

To throw away something that still is considered useable is often associated with guilty conscience and moral qualms (Klepp, 2001). Klepp's study was on clothing and describes how disposing of clothing is a painstaking process, where the clothing in question is moved around the house before the decision on disposal is reached. Cruz-Cárdenas & Arévalo-Chávez (2018) call these "transition areas," such as cellars, where objects are, deliberately or not, waiting for their exit from the household. The time between last use and when divestment decision is reached, can be labelled 'at mercy' (Klepp, 2001). A term that can shed light on this period, is products' 'lingering value' and the accompanying erosion of value or gradual downgrading prior to final disposition, to prevent the guilt or anxiety of the disposition (Türe, 2014). Such downgrading would appear through inappropriate transfer of a product to the next potential user, or through two strategies the author call 'brutal use' or' gradual garbaging' to use the object till the end.

For our theoretical basis, we use taxonomy developed by Jacoby et al. (1977) for describing consumer disposition behaviour. It includes the situational, personal and product related factors that influence the disposition choice, as well as the potential outcomes of the disposal decision on whether to retain the item or dispose of it, either permanently or temporarily (e.g., loan or rent it).

Several researchers have developed the taxonomy further to accommodate for the fact that divestment is a process of several stages, as described above. According to Dommer & Winterich (2021), the first step is to stop using an object, followed by decision on whether to retain the item or dispose of it, and finally choosing where to dispose of it. Hanson's (1980) paradigm for consumer product disposition processes describes disposal as a process of four stages, starting from problem recognition, search evaluation, disposition decision and post-disposition outcomes. Poppelars et al. (2020) distinguish between divestment, disposition and detachment, where divestment is seen as the overarching term referring to the final phase of the consumption cycle, and that disposition and detachment happen simultaneously during divestment. Disposition is then the physical separation of the product, while detachment represents the mental and emotional separation of the product.

In this paper, we focus on products where the timing of the disposal seems to be "off", by studying why consumers keep products that either don't function properly or are just kept in storage.

## Methodology

For this study, six focus groups were carried out, with 36 participants in total. The number of participants in the workshops varied between three and eight. The composition of focus groups included focus groups that were gender specific (men/women), or with special interest in environmental issues. The participants were asked to send two pictures in advance of products they had that either surprised them positively or negatively with regards to lifespan. Over the focus groups, each participant was asked to share the reasons for the photo they had submitted, and the other participants joined in with their reflections, thoughts, and own experiences.

The focus groups were recorded and transcribed. The transcripts were coded with a combination of both deductive and inductive approaches, where deductively prepared codes were prepared based on the interview guide topics and the project application. This was augmented with themes appearing from the material with an inductive approach. Through a collaborate effort between the three researchers involved in the analysis using NVivo software, 9 main coding categories were identified. Each of these has a number of subcategories, Table 1.

For this paper the responses from the 'Not satisfied' subcategory is used in the Results and analysis section. The rational for this is that both product groups are representations of products that have failed to satisfy the expectations respondents had to them.

| Main analytical category | Subcategories |
|---|---|
| Acquisition | Second-hand purchase; Forms of ownership; Planning |
| Use | Satisfied; Not satisfied |
| Maintenance | Protection: Cleaning; Repair; Adjustments |
| Disposal | |
| Quality | Brand; Design; Complaints; Returns |
| Lifespan | Years |
| Life event | |
| Labelling | |
| Resources | Knowledge; Materials; Price; Time; Transport |

**Table 1. Analytical categories and sub-categories.**

## Results and analysis

One of the inductively found aspects is a number of products, that the owners were dissatisfied with, but still chose to keep. We noticed two particular features: 1) Products that were still fully functional, that were taken out of active use and stored without any apparent intention of using them again; and 2) Products that were flawed but still were retained in active use. The timing of disposal of both product groups seems to be delayed. We start by giving examples of products from both categories and continue with analyzing the suggested reasons behind delayed divestment.

### *Inactive redundant products*

This group of products had representation from all three product categories discussed in the focus groups: Clothing, furniture and electronics. An example of the latter is the hot dog heater (Figure 1). The owner explained that it was both impractical to use and not really needed, as other household equipment already can deliver identical functions. Another example is a robot vacuum. The owner describes it as a mistaken purchase, as the robot vacuum is too high to get under the sofa. The owner had checked the height of the robot vacuum without noticing that this measure was given without the wheels needed for it to move around.

**Figure 1. Dennis' (M-63) Hot dog toaster.**

The following is part of an exchange on a pair of cross-country pants owned by a man in his 70s. He considered them too lined and subsequently too warm, and the tightening mechanism around the waist had broken. However, he had managed to fix it with a shoestring:

*Man: (…) And so it never worked, it probably hung there for God knows, I don't know how many years.*
*Moderator: Ok, but you have not disposed of it?*
*Man: No, No I have not disposed of it, no no, disposing of it, that is not that easy, and it's not possible to sell it either, so it'll be left there hanging for, I don't know how long.*
*(…)*
*Female: God, they [the trousers] must be annoying, they have been annoying you for ten years!*
*Man: Well yes, I keep moving those things around…*

Examples from furniture is an old folding table that was considered as rather unpractical as it was hard to fit chairs under it. This was ready for going through a next step in 'a cascade': To be moved from the living room to the cabin. A probable final step: disposal, was still unarticulated.

The common denominator here was that all these products had full functionality, but that the users either did not have a need for these functionalities any longer, or that such needs were covered by other products or solutions.

With reference to the terms suggested by Poppelars et al., (2020) one could speculate if these products have progressed more on a mental and emotional separation of the product (detachment), but less so on physical separation (disposition). Or is it rather the other way around, as the products often appear to be out of sight, and as such is physically separated, but are still kept as the emotional separation is harder?

### *Faulty products in active use*

Examples of flawed products with long lifespans against the odds within electronics include a dishwasher and a SodaStream that both need to be started in a special way to function, requiring extra skills from their users, a tumble drier where the drum needs to be pushed manually to start rotation, a washing machine where spin-drying can't be used because it destroys clothes, and hair dryer that does not have the heat function (Figure 2). The owner in her 30s explains:

*That hairdryer, it was also a bit cheap from Clas Ohlson, I remember when I bought it and then the hot air stopped working very quickly. So.. and then I just haven't bothered to do anything with it because I don't use a hairdryer that much. (…) I've probably had it like seven years, (laughs). (…) I use it. It works, it just takes a lot longer than with a hot hair dryer, so that's probably why I haven't bothered to do anything with it. (laughter).*

**Figure 2. Charlotte's (F-37) hair dryer.**

For clothing and furniture, many of the problems were related to poor aesthetic properties, where the materials have not tolerated use and have become so unsightly that the user for example chooses to wear the clothes only under other garments or at home, or for furniture, cover it with a tablecloth.

Further, some of the furniture was found very impractical, like a sofa that cannot really be sat on, as the upholstery material does not tolerate some common clothing materials such as denim jeans, and the seat pillows slip off when you sit on it. Within clothing, the owner in her 70s explained how the zipper in her jacket was so poorly sewn that it was very hard to close. She had to step into her jacket while the zipper is closed to be able to wear it. As with electronics, some of the furniture was partly broken but retained some function, such as a dresser that could be used as a TV cabinet even when the drawers could not be opened.

A common nominator for all these examples is that the products have some of the function left. They have not reached the first step of the disposition process where the owners stop using them (Dommer & Winterich, 2021). This could be interpreted as some of the core functions of the product still is intact, whereas the additional functions or services the products originally could provide were ‘nice to have’.

## Discussion

So, what keeps the owners of products with one of these features from disposing them? Other consumers would probably reason otherwise and replace these products without guilt or moral qualms. In line with Jacoby et al, (1977), we find that there are situational, personal and product-related factors that influence the divestment choice. Based on the material, we suggest that the users still feel that these products have some (lingering) value attached to them, either economic, emotional, social, or practical use value. Also, their own ethical considerations on non-wastefulness have an impact, as well as the situational aspects such as available storage space, transport possibilities and accessible divestment options.

### *Economical*

One reason appears to be some kind of mental depreciation. Some of these products were associated with high prices, and the owners felt that it was too early to throw them away. As the owner of a leather coat phrased it when he was asked why he still held on to it: “*I cannot afford to throw it away!*” For some of the faulty products still in use, the cost of replacement would be high, such as for the washing machine and the dryer. In these cases, the user is saving money when keeping on using the machines.

Another related aspect is that Norwegians in general live in rather spacious dwellings, where products may be stored away in attics or storage rooms and be kept out of sight. As such, they can be kept without a constant reminder that they are there.

### *Ethical*

Some of the respondents expressed sustainable or ethical motivations related to non-wastefulness and did not want to dispose of the products before they were used up, despite the poor functionality, they still have ‘lingering value’ (Türe, 2014). For the cross-country pants that were kept despite any intention of using them, it seems to be more of an indication of moral qualms (Klepp, 2001).

### *Social*

Some of the products were received as gifts. This might make it harder to dispose of them, even though you have little use for it, or find it ugly (Cruz-Cárdenas & Arévalo-Chávez, 2018). One example was a daughter who received a microwave from her father as a present. If she disposed of it, she felt that she would say to her father that she really would not appreciate his present, and she obviously would not like to tell him off like that.

### *Emotional*

According to reviewed literature, many products are retained due to emotional attachment. This was seldom the case in our study, because the examples we focused on, where products people were dissatisfied with. However, some of the inherited items fitted with this description, as well as some products with aesthetic properties that the owners appreciated, even though the product otherwise would not function as expected. Some inherited products were kept without any intention of using them further. With inheritance comes some legacy and that it is a product that you are expected to take care of before it is passed on to the next generation. So, not just waiting for an occasion in your own life when the gadget, garment or furniture suddenly would fit, but even when occasions arise in other people's lives. For instance, when your children are moving out, maybe they then would need that thing in your storage?) Such products often have an emotional value. The folding table could be an example of this, although the owner stated this somewhat indirectly ("an old table").

### *Intentions*

We also saw that some products were retained with the intention of potential future use where needs may arise or circumstance change. For example, the owner of the robot vacuum cleaner was moving and would now test if it could be used in the new dwelling.

In some cases, the intention was delayed, as the owner claimed it was too late to forward a complaint to the store or manufacturer. Under such circumstances the product could have been saved through repair or replacement.

### *Sustainability*

An overarching question is to what extent any of these product features can be said to be environmentally sustainable. Intuitively one would be tempted to say that faulty products that are kept in active use are sustainable in this sense. They postpone the purchase of new product that would cover the same need, so the lifespan of the product is increased at some cost (lower functionality). However, there could be hazards resulting from the use of such products: electrical faults, an electrical shock, or other health hazards like cuts or bruises, or even fire. They are also a frequent source of dissatisfaction for their owners.

The sustainability of products that are kept but that have gone out of use may intuitively appear less likely. They may, however, function as backup, in case currently used products for a specific task should fail. If these products could find their way to a new user, or even a new area of use, the active lifespan even of these products could increase. On the other hand, quite a few products are susceptible to obsolescence (through changes in technology or fashion). They typically take up physical storage space, which can potentially slow down the acquisition of new products (Cruz-Cárdenas & Arévalo-Chávez, 2018).

## Conclusions

This paper has identified two product types that for a variety of reasons are kept, despite failure to meet owners' expectations (satisfaction). This is one property that unites these products, however even some reasons behind holding on to them appears to apply for both product types. However, there are also differences: The flawed products that are kept in use, seem to fit to the 'lingering value'-concept, whereas this may not explain the inactive product type. For the latter reasons are more tacit, however they suggest a negotiation between the detachment and disposition-concepts, were physical and emotional separations sometimes appear to be in accord with each other, other times they conflict.

There are several options for avoiding or reducing these two product types. To avoid inactive items, a lot can be done during acquisition, as mistaken purchases and gifts constituted a large share of these. Further, facilitating options for reuse can contribute to re-activate these items. Many of the faulty products could be repaired or refurbished, and many disfunctions could have been avoided by guidance in stores on proper maintenance of products.

# What sustainable fashion retailers presume about consumer motivations and how they try to persuade consumers to purchase their product

**Toebast-Wensink A.**[a,b], **van den Broek K.L.**[a], **Timmerman T.**[b]
a) Utrecht University, Utrecht, The Netherlands
b) University of Applied Sciences Utrecht, Utrecht, The Netherlands

**Keywords:** Sustainable Fashion; Consumer Behavior; Retailers; Marketing; SHIFT Framework.

**Abstract:** Retailers play an important role in persuading consumers to purchase sustainable fashion (SF), but little is known about how, and why, SF retailers persuade consumers. This research aims to understand their choices for marketing and communication tactics. We interviewed 25 SF retailers about the drivers that they presume motivate consumers' purchases, and about the drivers they actually target in their marketing practices. Our findings show that retailers do not base their marketing tactics on what they presume drives SF purchases: most retailers presumed that personal benefits and advantages motivate SF purchases, however, they targeted cognition-related drivers in marketing communications. Retailers' current marketing communication endeavors show a disproportionate focus on persuading consumers to choose SF as a category, instead of persuading consumers to purchase their specific products. Based on this study, we recommend researchers and marketeers to support SF retailers with knowledge of effective marketing and communication tactics to address SF purchase behavior change, and the industry and public authorities to provide an effective SF information campaign for consumers.

## Introduction

Sustainable Fashion (SF) retailers play an important role in promoting SF consumption, as fashion purchases are often impulsive and decided upon during shopping activities (Maldini, 2019; Yang et al., 2017). SF retailers can apply several marketing communication tactics (such as social media, PR, sponsoring, events, and commercials) to persuade their target audience to purchase their products or services (Strähle & Hauk, 2017). However, compared to their non-SF counterparts, they have an additional challenge, namely changing their consumers' behavior from purchasing sustainable to non-sustainable fashion.

A plethora of studies looked into drivers of sustainable fashion behavior, however, insights into how SF retailers perceive consumers' drivers, and how they actually persuade their target audiences to purchase their SF, is lacking (Mukendi et al., 2019; Strähle & Hauk, 2017). This study aims to answer the following two research questions: 'What are the presumed drivers of consumers' SF purchases, according to SF companies?' (RQ1) and 'What behavioral drivers do SF companies target in their marketing endeavors?' (RQ2). Below we describe the applied research method, and report our results, before concluding with a discussion.

## Method

We took a qualitative approach and interviewed 25 managers of SF retailers (semi-structured interviews). We composed the interview sample based on a list of contacts provided by Dutch sustainability associations, and SF retailers known through the professional networks of the research team. The retailers were firstly questioned about what they *presumed* to be drivers of consumers' SF behavior (RQ1) and secondly about the drivers they *target* in their current marketing endeavors (RQ2).

Retailers' responses were coded using a deductive thematic analysis approach (Braun & Clarke, 2013; Linneberg & Korsgaard, 2019). We applied the SHIFT framework (White et al., 2019) as an analytical lens to categorize and compare the retailers' responses. SHIFT elaborates on five routes to sustainable behavior change, namely Social influence, Habit formation, Individual Self, Feelings and Cognition, and Tangibility. For each route, an overview is provided of persuasion techniques and marketing tactics based on drivers for sustainable behavior change. To categorize retailers' *presumed* drivers of consumers' SF purchases (RQ1), codes were based on the five principal routes of SHIFT. To categorize which drivers of consumer SF purchases retailers *target* in their marketing endeavors (RQ2), codes were based on the sub-categories per SHIFT route, as these deal with specific techniques that can be applied to a particular route to persuade consumers towards sustainable behavior change (White et al., 2019). Multiple codes were assigned if needed. The applied coding framework is available upon request.

## Findings

122 statements were coded as *presumed* drivers (RQ1), and 269 statements were coded as *targeted* drivers (RQ2). The notable difference in number of coded statements was due to the observation that the second research question invited participants to elaborate more, while the first research question led to more succinct responses. In Figure 1, the total number of applied codes is displayed in percentages, comparing the distribution of presumed and targeted drivers.

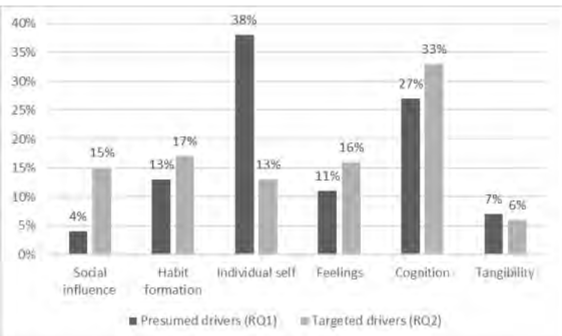

**Figure 1: Spread of presumed and targeted drivers over SHIFT routes. 'Feelings and Cognition' route is displayed as two separate routes as interview statements also appeared to make this distinction.**

Figure 1 shows that SF retailers mostly presume *Individual self* drivers to influence SF purchasing (38%). However, in their marketing and communication endeavors *Individual self* drivers are clearly less salient (13%). In other words, SF retailers expect that consumers purchase SF for personal benefits, however, addressing personal benefits is not the main focus of their marketing and communication tactics. Additionally, Figure 1 shows that SF retailers' most salient route for persuasion is *Cognition*; all other SHIFT routes were less salient.

Below we elaborate on the results per SHIFT route, starting with an explanation of how we interpreted the route and followed by our findings for RQ1 and RQ2.

### *Social influence*

This route to persuade consumers to purchase SF is through the presence, behaviors, or expectations of others. What is commonly done, approved or disapproved by others can strongly influence SF purchasing (Ciasullo et al., 2017; Kang et al., 2013; Kleinhückelkotten & Neitzke, 2019; Mukendi et al., 2019; Pantano & Stylos, 2020).

Retailers mentioned *presuming* that other people influence consumers' purchasing SF least frequently (4% of the RQ1 coded statements). Statements coded on this route referred to, for example, conveying status by wearing SF, and how SF retailers can work together to change consumers' mindset.

15% of the coded RQ2 statements were coded as *targeting* social influence, for example referring to sharing blogs/ interviews with the founders, building communities through (physical) events and/ or (online) social media, and cooperating with influencers as part of their marketing communication tactics: *"e.g., with the Fashion Revolution. She's even mentioned us in her book. I think that also gives a bigger impact to our mission and purpose"* (retailer 16).

### *Habit formation*

This route to persuade consumers to purchase SF addresses habits and ease of consumption. Habits are automated behaviors due to regularly encountered contextual cues

(Klőckner & Verplanken, 2019; Kurz et al., 2015). For inexperienced SF consumers, switching to SF purchasing means interrupting habitual fashion behavior, which requires a high willingness to change (la Rosa & Johnson Jorgensen, 2021; Wiederhold & Martinez, 2018). Interventions that break repetition or provide consequences, such as rewards or penalties, can be applied to motivate consumers to purchase SF (Bolderdijk et al., 2019; Gordon et al., 2011; White et al., 2019).

13% of the RQ1 coded statements referred to Habit formation. Most of these statements indicate how retailers *presume* accessibility and availability of SF motivate consumers to purchase SF. Additionally, retailers expect life-changing events to drive SF purchases (e.g., becoming a parent), and to how SF retailers presume repeating after a first SF purchase.
17% of the RQ2 coded statements were coded as Habit formation. Here, incentives were most frequently mentioned, e.g., in the form of coupons, gift cards, trial periods, raffles, and discount codes. As one retailer stated: *"You can educate what you want and explain how it works to produce jeans and how much water it costs, but in my experience, creating incentives works best"* (retailer 5). Only a few RQ2 coded statements did not *target* short-term tactics, but referred to improving accessibility and availability, for example by using icons to structure different SF concepts to make it easier for consumers to find their preferences. One retailer specifically targeted a life event to disrupt automated fashion behaviors, namely offering Rental specifically for holiday dresses (new business model).

### *Individual Self*
This route to persuade consumers to purchase SF is through addressing personal benefits or personal preferences. Retailers can emphasize utilitarian benefits (e.g., aesthetics, price, and quality)(Ciasullo et al., 2017; Lundblad & Davies, 2016; McNeill & Venter, 2019; Rahman & Koszewska, 2020; Tey et al., 2018), or emotional benefits (the affective feeling towards the product)(Jung & Jin, 2016; Sung & Woo, 2019). Emotional benefits can be addressed by providing symbolic benefits through branding, which has been found to be a powerful instrument for behavior change (D'Souza, 2015; Grubor & Milovanov, 2017).

Most of the RQ1 coded statements (38%) referred to Individual Self as *presumed* driver for SF purchases and reflected the retailers' assumption that personal benefits influence SF purchases. Most of these statements referred to price (54% of the coded statements on this route), for example referring to presuming consumers purchase SF as an investment piece, or desire wearing expensive brand for less money through Rental. Additionally, 28% of the RQ1 coded statements on this route is related to product or style: "[Sustainability] *is the second thing that they're looking for. First, they must like it, or appreciate the style"* (retailer 24).

For RQ2 only 13% of the coded statements referred to *targeting* the Individual Self (second least coded for RQ2). These statements describe referring to utilitarian benefits (e.g., product quality, style, or fit) or motivating consumers to purchase SF by addressing self-efficacy, e.g.: *"Well, I always choose to emphasize the fact that you can do something about it. We say: if you order our boxer shorts, you immediately save 560 liters of water"* (retailer 18).

### *Feelings and Cognition*
Feelings and Cognition are different routes to motivate sustainable consumer behavior, and most consumers take one of these routes to action (White et al., 2019). The *Feelings* route assumes that consumers are driven to purchase SF by addressing positive and negative emotions, and explains how purchasing SF makes them feel good, or prevents them from feeling bad (Taufik & Venhoeven, 2019). The *Cognition* route assumes that consumers are motivated to purchase SF through information and their knowledge of sustainable and unsustainable fashion (Abrahamse & Matthies, 2019; Kang et al., 2013).

27% of the RQ1 coded statements relate to Cognition (second most coded for RQ1), and 11% of the RQ1 coded statements referred to Feelings. Retailers *presume* a growing awareness of the need for sustainability drives consumers to purchase SF; however, they additionally perceive that consumers find sustainability in fashion hard to act on: *"When it comes to fashion, they kind of have these blinkers on and don't know what to do"* (retailer

7). Some retailers presume that consumers feel gloomy about sustainability: *"You can feel how heavy the whole topic of sustainability feels for a lot of people. As if nothing is allowed anymore, or as if things are being taken away from them"* (retailer 15).

Most RQ2 coded statements refer to Cognition (33%), and roughly half of that to Feelings (16%). Almost all retailers indicate conveying information about SF and its impact, for example in blogs, by collaborating on documentaries, or by participating in educational events. Several interviewees explained how being able to share sustainability-related content is an advantage: *"We do explain more about the way we work than other businesses perhaps; they may leave that information behind or talk about 'the way to sustainability' in vague terms that do not mean anything. We can sincerely say that we stand for what we do"* (retailer 13). Adding to this, several retailers mentioned being careful with claims about sustainability, because *"we need to stay accurate and balance on the right side of greenwashing"* (retailer 9). In addition, retailers pay attention to their tone of voice when conveying information, for example *"without pointing fingers"* (retailer 2). One retailer perceives the danger of greenwashing claims as a hindrance to marketing communication: *"We overthink sustainability references ten times, because if we use the wrong formulation, that is potentially a huge issue. When you talk about sustainability, you are not allowed to make mistakes, so sometimes we cannot propagate our sustainability strategy the way we would like to"* (retailer 11).

### *Tangibility*

This route to persuade consumers to purchase SF through addressing awareness of the consequences of consumers' personal sustainable or unsustainable fashion behavior. Sustainability is an abstract topic for many, and helping consumers understand how their purchase can make a difference can motivate SF purchases (Chi et al., 2019; Elsotouhy, 2020; Kim et al., 2015; Mukendi et al., 2019; Vehmas et al., 2018).

Tangibility was second least coded for RQ1 (7% of the RQ1 coded statements). Most of these referred to *presuming* that consumers do not want to 'add to the problem' anymore, e.g. after seeing a documentary about the impact of non-SF, driving them to purchase SF.
Only 6% of the RQ2 coded statements relate to Tangibility, mostly referring to communicating concretely about the impact of sustainable and unsustainable fashion with for example pictures or listing some facts about SF on social media. However, one interviewee adds some nuance: *"I do see a good response on Instagram with these posts* [with lists/tips]. *People save them, so people do find it interesting, but I do not think it persuades them to act in relation to my shop"* (retailer 5).

## Discussion

This study provides insights into SF retailers' perception of drivers for SF purchases and how SF retailers currently try to persuade consumers to purchase their SF. Most retailers did not target the same drivers they presumed to motivate consumers to purchase SF.

Retailers widely presumed *Individual self* factors to motivate consumers to purchase SF, in other words they expect that consumers purchase SF for their own benefit (i.e., functional, aesthetic, effort, or affordability). However, Individual self was not so salient in their marketing and communication. We would expect when retailers presume this route to be important, they would pay more attention to persuading consumers by addressing personal benefits or preferences.

Retailers' most salient *targeted* driver was Cognition. This may be explained by SF retailers motivation to i) stay factual and precise as they are afraid of greenwashing claims, ii) feel the need to explain why SF is more expensive than fast fashion alternatives, and iii) are passionate about their sustainable choices and enthusiastic about sharing their knowledge, as apparent in the interview discussions. Retailers perceive that consumers are confused about sustainability terminology (Han et al., 2017), and even though the industry should provide standardized labels with product information (Weiss et al., 2014), this has not been implemented, so SF retailers tend to function as educators of their consumers instead (Puspita & Chae, 2021; Todeschini et al., 2017).

Subsequently, retailers' focus on targeting Cognition drivers implies that they pay more attention to persuading consumers to choose SF as a category, than to persuade consumers to purchase their specific products, even though they do need to attract sufficient consumers to keep their business running. Therefore, we recommend that the industry and regulators put more effort in development and deployment of an effective information campaign to persuade consumers to choose SF, so SF retailers can focus on applying the most effective marketing communication tactics to persuade consumers to purchase their specific products/ brand, as only products and brands that appeal most to the consumer will be bought (Mukendi et al., 2019).

Finally, another possible explanation of why retailers seem not to base their marketing tactics on what they *presume* drives SF purchases, is a lack of awareness of other marketing communication techniques to address SF purchase behavior change. This implies a research-practitioner knowledge gap, which can be resolved by providing SF retailers with knowledge of marketing communication tactics. The overview of techniques and interventions per SHIFT route may provide practitioners with inspiration to test alternative marketing communication tactics.

# Squaring the Circle on PPE: a Systemic Approach to Designing and Repurposing Gowns

**Katherine Townsend[a], Tom Dawson[b], Eloise Salter[a], Karen Harrigan[a], Sonja Šterman [c]**
a) Nottingham Trent University, United Kingdom Affiliation, City, Country
b) University of Exeter, United Kingdom
c) University of Maribor, Slovenia

**Keywords**: Circular System; Design for Reuse; Reusable PPE; Repurposing; Net Zero.

**Abstract**: The lack of a systemic approach to the provision and servicing of reusable personal protective equipment (PPE) currently limits possibilities for extended use. The paper documents the research and development of a reusable PPE isolation gown and its' integration within a virtuous, circular system, which tackles the human and environmental issues caused by single-use products, through a holistic design for reuse approach. The dual aim of the research is to enhance the design of PPE gowns to improve user experience while decreasing medical plastic waste, in line with net zero targets. The collaborative design of a reusable PPE/surgical gown is the outcome of empirical research supported by a distributed manufacturing network, comprising partnerships between academia and local specialist textile, gown and laundry suppliers and a company focused on enabling fully circular textile systems. The co-design methodology has been implemented through engagement with the industry partners, by analyzing the PPE needs of the active healthcare user, and through wearer trials with NHS trusts in the UK. Following interactions with all stakeholders in the supply and value chain, we have devised a Circular PPE System that addresses the significant barriers relating to the longevity of reusable gowns. The model is based on developing net zero processes, such as fibre-to-fibre recycling, zero waste pattern cutting, design for reuse tactics, low environmental impact decontamination hubs, medical and creative repurposing strategies to extend the functional life of the garment and its materials.

## Introduction

The issues associated with single-use personal protective equipment (PPE)[1] and the plastic waste generated by healthcare organizations were exacerbated by the coronavirus pandemic, leading to a call by United Kingdom Research & Innovation for the development of 'reusable products to meet net zero targets' (UKRI, 2020).

In response, the dual aims of this empirical investigation were to design a fit-for-purpose reusable PPE isolation gown and reduce the amount of single use gowns being disposed of (UKRI/ AHRC, 2021). By early 2022 we had developed a reusable gown prototype that met the prerequisite 'EN 13795 industry standards' for CE/ UKCA marking and the 'research through design' aims of the brief (Townsend et al. 2022). The resolution and testing of the gown, aligned with product longevity and closed material loops was enabled through a 'distributed manufacturing' and servicing network (Kohtala, 2015).

Research by Circular and Sustainable Textiles and Clothing (CISUTAC, 2022) is focused on how northern European societies can replace the current fast fashion model, including workwear and PPE and active wear, with zero waste, circular alternatives. The four key areas that need to be addressed within a 'virtuous system' are defined by Zero Waste Europe (2023) as:

[1] PPE refers to Personal Protective Equipment though technically in the medical context what are commonly referred to as PPE are regulated medical textiles and covered under the Medical Device regulations and standards rather than the PPE or health and safety regulations and standards. Reference to PPE in this document will be the equivalent of referring to Regulated Medical Textiles including masks, aprons, isolation, surgeons' gowns and surgical drapes.

1. Design for physical and emotional durability
2. Demand-driven production to phase out unsolds and discounts
3. Full supply chain transparency and traceability post-sale
4. Extending the use-phase after first ownership.

We address similar criteria in the development of a reusable PPE gown, using design as a vehicle to mediate between multiple stakeholders in the distribution network, towards a circular textile system (Zaplata et al., 2022). The core aim is to minimize the environmental impact of PPE, by developing a sustainable, novel and inclusive value chain (CISUTAC, 2022).

The paper describes the methodology employed to develop the PPE gown prototype, drawing upon the active users' requirements, literature and gown reviews. We explain how we established links with a distributed manufacturing network and circular textile systems provider and how the positive improvements of the gown were counter-balanced by perceptions of negative environmental issues linked to disposal strategies. Finally, we discuss how we responded to these issues by developing a Circular PPE System to address current barriers to meeting net zero targets.

## Designing a Reusable PPE Gown with Active Users

The methodology drew on the teams' experience of conducting 'participatory research through clothing design' with overlooked fashion demographics (Townsend & Sadkowska, 2020). This earlier work combined the principles of 'co-design' (Sanders and Strappers, 2008) with insights into the 'lived experience' (Eatough & Smith, 2017) of the 'active user' (Kohtala, Hyysalao & Whalen, 2020).

PPE gowns are paradoxical items of clothing; a medical product designed to protect the healthcare worker and patient *and* a generic item procured en masse, placing the recipient in the 'passive user' domain (Strappers, 2006 cited in Kohtala et al. 2020). Following a literature review and interviews with procurement and medical leads in 2020 we identified nurses, particularly women, as being active users of PPE by vocalising issues and customising the one-size gowns they were often allocated. In a reversal of Manzini's concept of "diffuse" and "expert design", the nurses' diffuse experiences of wearing PPE made them the experts (Manzini 2015, p.37).

### *Survey and gown review*

While it was crucial for nurses to be part of our network, direct access was unfeasible due to Covid-19 restrictions. Using our initial findings we devised an online questionnaire addressing key aspects of isolation gown design and use (Šterman et al. 2022). The PPE Gown Survey (2022) was circulated via healthcare partners in the East Midlands, UK. Analysis of the 130 responses reinforced issues with sizing, fabrication and heat stress (e.g. McQuerry et al. 2021). Providing space for additional feedback elicited commentary on nurses' 'person-product relationships' (Niinimäki & Karell, 2019).

A gown review of 30 disposable and reusable products enabled the team to collate garment specifications, fibre content and design details. The technical measurements provided quantitative data, complemented by the qualitative insights from the survey and through sensorial impressions noted by trying the gowns on. By studying this information, the team devised a medium-sized pattern block and sourced a fluid repellent, breathable textile, similar to the more comfortable, reusable gowns. Garment toiles were created incorporating multiple cuff, neckline and fastening solutions.

## Developing the Distributed Network: fabrication, production and servicing

Following 9 months research and development of the Style 1 gown prototype, the original named manufacturer failed to support the sampling/ testing process. This was one many "challenges encountered when confronting the theoretical framework of new circular economy business models with the material reality of design collaboration and prototyping." (Earley & Forst, 2019, p.1). We sought a replacement manufacturer through the Textile Services Association, who had made the case for 'reusable over single-use gowns' during the pandemic (TSA, 2021). The TSA connected us with local fabrication, manufacturing and laundry providers situated within a 30-mile radius, as follows.

Toray Textiles Europe Ltd (TTEL, 2020) are producers of polyester and nylon woven textiles for a variety of protective clothing contexts, notably DWR (durable water repellent) carbon coated polyester PPE gown fabric. TTEL hold OEKO-TEX® certification, have been ISO14001 accredited since 1998, and maintain an environmental management system to support their customers to use / re-use / re-cycle and dispose of its fabric and packaging in an environmentally responsible manner.

Anze Ltd UK (2022) are a manufacturer of sustainable healthcare apparel, with over 25-years of experience of producing and supplying reusable surgical gowns and drapes to the NHS. The company was involved in drawing up EU-wide standards which have shaped the reusable PPE industry, and are seeking smarter, greener solutions with a variety of partners.

Synergy LMS (2020) offer a range of linen services tailored to the needs of healthcare providers in the UK, including rental service of reusable PPE (washed at 71° C) and surgical gowns (sterilization at 134° C) to a total linen management solution encompassing the distribution and collection of ethically sourced products to and from medical wards.

### *Manufacturing the gown*

On comparing our Style 1 prototype with Anze's PPE gown we found many similarities, including the 97.3% Polyester/ 0.7% Carbon fabrication (by TTEL), general style and dimensions. Anze's gown was supplied to healthcare providers nationwide and throughout Western Europe. The company offered us the opportunity to integrate our design modifications with their tried and tested model which included the following:

- Reshaping the font/back neckline
- Reshaping the sleeve head
- Shortening the sleeve
- Reducing the number of fastenings
- Introducing an XS size
- Recalculating the grade rule (XS-5XL).

**Figure 1. Anze/NTU/Revolution-ZERO reusable PPE isolation gown prototype, 2022.**

Anze Ltd sampled the prototypes in EN 13975 certified conditions and provided access to their CAD/CAM system, enabling us to adjust the pattern blocks, nest and lay plan. During this time, the company formalised a collaborative partnership with Revolution-ZERO which included the Anze/NTU gown (Figure 1). Revolution-ZERO (2023) has a mission to displace single use medical textiles with reusable alternatives that are more effective, economic and sustainable. To do so they work with partners to provide technology enabled solutions for net zero circular economy, or cradle-to-cradle medical textiles and PPE.

### *Wearer trials and key findings*

With the support of Synergy LMS two wearer trials were conducted in 2022 with 24 participants working in ICU wards at the University Hospitals of Derby and Burton NHS Foundation Trust, and 12 participants at Nottingham University Hospital Trust. In addition, Revolution-ZERO coordinated a third trial with short-sleeved variation of the gown with 10 ICU staff in St Helens and Knowsley NHS Trust and a fourth trial at Royal Cornwall Hospital Trust, for 14 participants.

Feedback from the trails was positive, with the comfort and fit of the reusable gowns outperforming single-use products. Commentary from wearers evidenced 'improved comfort' based on 'cooler fabrication', 'better fit' and the desire to wear reusable PPE as being 'more sustainable'. Suggestions were also made for minor modifications to 'cuff depth' and 'gown length'.

The main finding was that the development of such a high quality, durable gown could potentially create an additional environmental problem, relating to what happens when it reaches its maximum-use threshold? We discovered how post-laundry practices include shipping used gowns offshore to be used by medical charities in developing economies or sending them to landfill. This limited approach to reuse and disposal led us to review the original aims of the project and extend it by 6-months to facilitate research into repurposing strategies.

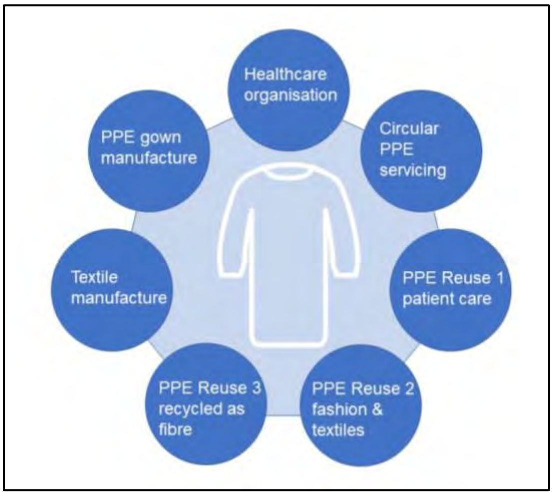

**Figure 2. Circular PPE Gown System, Townsend et al. 2023.**

## Circular PPE Gown System: design, use and repurposing

Undertaking wearer trials of the gown highlighted the problems associated with "a linear model that is characterized by low rates of use, reuse, repair and fibre-to-fibre recycling of textiles..." (European Union, 2022).

Following the coronavirus pandemic, when reliance on offshore suppliers and unsuitable PPE exacerbated the crisis for nursing staff, there were calls for a local approach to PPE manufacture linked to the need for extended product use (Henshall, 2023). As illustrated in Figure 2, the working model for our Circular PPE System focuses on increasing the current use phase by the Healthcare organization, to encompass three stages of Reuse. The model echoes the textile sectors' aspirations for Workwear and PPE through "implementing a fully circular value chain, incorporating cost efficient dismantling, sustainable and circular designs, and approval from public authorities." (CISUTAC, 2022).

The seven stages within the system begin with Textile manufacture and continue in a clockwise direction to PPE Reuse 3. Further research is being undertaken to support the functionality of the system, employing understanding of textile design, manufacture, and re/use to support value creation at each stage (Zaplata et al., 2022).

### *Textile manufacture and PPE Reuse 3: recycled as fibre*

Toray Textiles Europe Ltd, recognizes how "the growing demand for textiles is fueling the inefficient use of non-renewable resources, including the production of synthetic fibres from fossil-fuels." (European Union, 2022). TTEL utilise 100% recycled polyester fibre and recycle 60% of the water used in their weaving production. They aim to remove the DWR carbon coating from their textiles to recycle the 100% polyester to fibre and yarn, at scale. "The ultimate goal is to produce a biodegradable PPE textile" (Else, 2023).

### *Gown manufacture*

Anze Ltd continue to facilitate minor modifications to the Anze/NTU/Revolution-ZERO gown and to produce bespoke specifications for specific customers based on demand driven production. They plan to develop a Petite range (XS-3XS) and offer reusable PPE accessories such as headwear to accommodate nursing staff from ethnically diverse groups. Anze's goal is for the circular PPE system to facilitate a "gown-to-gown" model, with the product being recycled and remade, in lieu of a compostable, garment (Lamb, 2023).

*Healthcare organization*

In October 2020, the NHS became the first national healthcare system worldwide to set "a carbon net zero goal" with an aim to reach net zero in direct emissions by 2040, and then in July 2022 the first to embed this target into legislation (NHS England, 2022). This creates the conditions and will for a rapid and large-scale shift towards circular medical textiles, but it is a complex task – the NHS and its supply chain accounts for "10 per cent of UK GDP and employs £1.4 million people" (UKRI, 2022) Consequently, "a move from linear to circular PPE requires new ways of thinking and operating, involving cross-sector collaboration mixing clinical, industrial, commercial, scientific, and academic expertise" (Dawson, 2023).

*Circular PPE servicing*

In April 2023 Revolution-ZERO will trial a ZER-DECON unit to reprocess and supply surgical textiles for orthopaedic theatres at St Michael's Hospital, Cornwall, UK (Henshall, 2023). The PPE servicing process will integrate Net Zero focused washers, dryers and reporting sensors and will include low temperature decontamination and reusable sterile packaging. The servicing model echoes the full supply chain transparency of the PPE circular system. Since setting up Revolution-ZERO in 2020, the company have secured interest from 150 NHS Trusts and have so far supplied more than 15 Trusts with reusable products and services.

*PPE Reuse 1: patient care*

There are numerous viable pathways for the proposed transition from a PPE gown to be used in patient care, including as an endoscopy or another health screening procedure. Some minor design interventions may be required to customize or prepare used gowns to be aesthetic and functional for outpatient and inpatient care, depending upon the specific context.

*PPE Reuse 2: fashion and textiles*

Synergy LMS are providing the research team with used gowns, including our own models from the wearer trials. This waste stream is being experimented with in PPE Repurposing Workshops at NTU by undergraduate, postgraduate students and staff from the Fashion, Textile & Knitwear department in the School of Art & Design. The gowns are being deconstructed and upcycled as innovative, 'intentional' fashion and textile design concepts (Niinimäki & Karell, 2019) (Figure 3). The lightweight, fluid repellent properties of the end-of-life garments are also being explored as outerwear for use by homeless members of the local community, by designing for physical and emotional durability (Townsend et al. 2023).

## Conclusions

The identified need to link the design and use of PPE products to a circular textile system has informed the specification, production, servicing and reuse of an isolation gown. The circular PPE gown will carry the names of the designers, manufacturers and servicing providers (Anze, NTU & Revolution-ZERO) so that once in commercial production and circulation the customers will be aware that they are buying into a circular product/ system that seeks to minimize waste during, and at the end of the products first lifetime. The 'gown to gown', 'cradle to cradle' model could be attributed to any PPE textile product, guaranteeing that once an item reaches its legislated use phase it will be returned to the servicing provider (Revolution-ZERO) to be repurposed.

**Figure 3. PPE Repurposing Workshop, NTU, March 2023.**

By providing sample gowns to healthcare trusts around the UK, we have secured further trials with NHS Highlands for use in dental practice, and for the short-sleeved version of the gown to be tested in an extended wearer trial in the St Helens and Knowsley Hospital Trust Intensive Care Unit. The researchers are seeking follow-on funding to support these trials and continue their design investigations into repurposing. For example, in the Reuse 1 phase, there are a plethora of potential uses/ users in patient care, particularly if items could be customised using textile techniques such as printing and embroidery to align items with medical procedures. As indicated by the ongoing repurposing workshops at NTU, there are multiple repairing, surfacing and construction approaches that fashion and textile designers could adopt in the Reuse 2 phase, by using gowns as a permanent waste stream.

## Acknowledgments

The research led by Nottingham Trent University has been funded by the Arts and Humanities Research Council, UKRI (AH/ VO15842/1). The research led by the University of Exeter was funded by SBRI Healthcare an Accelerated Access Collaborative (AAC) initiative, in partnership with the Academic Health Science Networks (AHSNs). The views expressed in the publication are those of the author(s) and not necessarily those of SBRI Healthcare or its stakeholders.

# Futuring alternatives biobased colour systems – testing possibilities of fading and redyeing with (SMC) Danish lifestyle companies

**Louise Permiin Tønder Jensen[(a)] , Monica Louise Gjøderum Hartvigsen[(a)]**
a) Designschool Kolding, Denmark

**Keywords:** Biocolour; Colour fade; Redye; Storytelling.

**Abstract**: The research presented in this paper focuses on how small Danish lifestyle companies view acceptable colour changes and in which timeframe fading and redyed colours could be implemented into their existing colour practices and thereby increasing the lifetime of textile products. To break down small Danish lifestyle companies' capacity to incorporate and benefit from the use of bicolourants, we have conducted research centered on a future scenario-based workshop with relevant local companies and an educational institution. The workshop was conducted in three parts: (i) Mapping the companies' current product lifetime systems; (ii) Dividing faded biocolorant samples in the scale of acceptance; (iii) Creating imaginary scenarios for a near-future timeline. From the subsequent discussion and evaluation of the workshop, four themes emerged: Missing transparency; the need for storytelling; challenge in future thinking; knowledge sharing. The themes could serve as future strategies to unfold how biocolorants could be implemented in Danish lifestyle companies, thus providing insights into how designers can work with biocolorants for alternative textile colouring systems in the future.

## Introduction

We live in an exciting era, a paradigm shift within textile production, that forces the industry to reimagine future strategies and systems for textile dye colours. Currently, textile dye colours are an important factor in production, in marketing, and of how textile products are consumed. Additionally, faded textile colours also determine the end of the product life cycle, as products with faded coloring are often discarded by the consumer (Cooper & Claxton, 2022).

But what if fading textile biocolorants were more widely accepted by consumers, thereby expanding the product's lifetime? What should such a new perspective on fading textile biocolorants entail? What kind of system thinking is needed to implement this mindset?

Around the world, research into alternative local textile production and colour systems are emerging. This paper draws on insights from textile researcher Rebecca Burgess's practice on building an alternative, local, and natural textile dye system in California, called *Fibershed* (Burgess et al., 2019). Fibershed is a vision that enhances social, economic, and political opportunities for communities to define and create their fiber and dye systems, thus redesigning the global textile process (Burgess, 2019, p.7). Burgess has catalysed a regenerative textile movement that seeks to create biocolorant products from *soil to skin and back to soil* (Burgess, 2019, p.7). This movement has inspired the organisation, *Fashion Revolution*, in establishing *Textile Garden* (Fashionrevolution, n.d.); an organisation that emphasise the potential in the resources, we have on our doorstep. Additionally, Textile Garden explores, how we can utilize natural resources in more creative ways, showcasing native UK wildflowers. By doing so, Textile Garden is sowing a seed of curiosity about the materials, dyes, and chemicals in our clothes.

Consumers are getting more familiar with what chemicals are being used to fixate the colour in clothes. Still, it is a limited number of fashion brands that have pursued a new orientation towards operating with environmentally friendly textile colours in production. The fashion brand *Puma* has launched a collection called 'Designed to Fade' in collaboration with *The Living Colour Lab;* the collection seeks to motivate their consumers to rethink the relationship with colours, as well as invite the consumer to consider faded colouring as beautiful. In Finland, the natural textile dye company *Natural Indigo* is collaborating with the Finish textile brand *Marimekko*; together they have launched a natural dyed shirt that fades over time and therefore ask the consumer for care and attention (Marimekko Corporation, 2020). This careful attention to product treatment invites the consumer to become familiar with the story of the biocolorants origin, their possibilities, and their limitations.

### *Framing our study*

This paper seeks to unfold Danish lifestyle companies' applicability in implementing the use of biocolorants and explore the qualities that this dyeing method embody. This paper's focus is an investigation of exploring how companies can introduce a new understanding and appreciation to fading bio-colours. The research presented in this paper is focused on what Danish lifestyle companies see as acceptable colour changes, and in which timeframe fading and redyed colours could be implemented into the company's current colour practices, to increase the lifetime of textile products. The research commenced with the workshop *Futuring biocolorants* conducted in November 2022 included representatives from four Danish textile companies.

The workshop was divided in three parts including (i) Mapping the companies' current product lifetime systems; (ii) Dividing faded biocolorant samples in scale of acceptance; (iii) Creating imaginary scenarios to a near-future timeline, to address possible implementations of biocolorants to the participants companies.

## Methodology

### *Research through design*

We are building on research through design, where insights are acquired through design practice, to uncover and understand complex and future oriented problems within the design field, also termed *wicked problems* (Farrell & Hooker, 2013; Godin & Zahedi, 2014). Exploring sustainable issues in relation to colour emphasises the 'wickedness' as sustainability deals with complex issues stemming from actors beyond this lifetime.

### *Action research*

As we are exploring alternative biocolorants for textile design through the data obtained during a workshop session, we are applying action research by using a *participatory design approach*. By constructing a workshop session as a research arena, the paper seeks to gain knowledge from the participants by actively involving the participants throughout the exploration (Archer, 1995; Koskinen, 2011).

### *Future scenario(s)*

A part of our workshop applies a futuring or scenario building as a way for the participants to actively engage in how the future implementation of biocolors could be explored. Thus, we are also applying an aspect of speculative design (Malpass, 2013), using future scenarios (Fahey & Randall, 1997) to envision how the future of biocoloured textiles could be integrated together with the participants.

### *Empirical data and evaluation*

The data used in this paper has been collected from the conducted workshop, *Future biocolorants,* in November 2022. In addition, we gained permission to record, photo-document, and retain all documents that were used during the workshop; these collected materials are also included in our data collection. The empirical data include recorded, photo-documented, and written material, as well as field notes, which were conducted after the workshop; the field notes reflect on the three introduced parts - *(i) Mapping, (ii) Scaling and (iii) Futuring* - and on what the participants had discussed during the workshop.

## Conducting the workshop

### *The participants*

The participants in the workshop included three representatives from smaller Danish companies within the textile sector and one representative from a Danish university college participated: An overview hereof is illustrated in table 1. It was found relevant to include the university college in our workshop, as it educates textile designers in close collaboration with the Danish textile and lifestyle sector.

| Participants | Company | Product(s) |
|---|---|---|
| Participant 1 | VIA University College | Design education |
| Participant 2 | Amoode | Women's Clothing |
| Participant 3 | Margit K | Scarfs |
| Participant 4 | TinyCozyStore DK | Textiles for bath interior |

**Table 1. Overview of participants.**

*First Part; Mapping a current product lifecycle.*

In the preliminary part of the workshop, we asked the participants to map the current lifetime system of a chosen coloured product from their company. Figure 1 depicts a participant is filling out the lifetime of their chosen coloured product. In the first part of the workshop the participants were asked to describe which material(s) or resources the product was made from, what type of colouring method had been used to colour the product and what happened to the product after end of use.

**Figure 1. A participant filling out the lifetime of a current-coloured product from their company.**

*Second Part; Scale of colour fade acceptance.*

In the second part, the participants were asked to fill out a scale of colour fade acceptance, by indicating how much colour fade they could accept for their products within a specific timespan. For this task, we had prepared a faded biocolour sample and chosen a timespan from the present to the near future: *Now, 1 month, 1 year* and *2 years*. In figure 2 and 3, two participants have filled out the scale of colour fade acceptance by drawing lines from the different timespans to the fade they could accept.

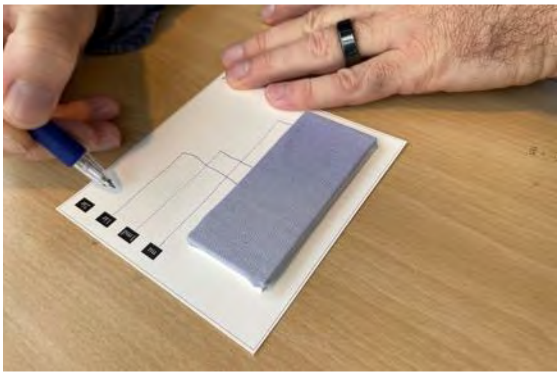

**Figure 2. A participant filling out the scale of colour fade acceptance.**

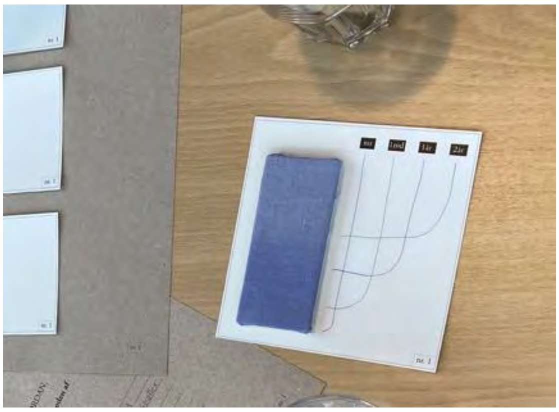

**Figure 3. A participant's scale of colour fade acceptance.**

*Third Part; Near future scenarios using biocolorants.*

In the third part of the workshop, we turned to the future and asked the participants to imagine a world where only biobased colours exists; thus, only having colours available which fades over time. We had prepared a timeline from 2022 to 2052. In figure 4, one of the workshop facilitators is explaining how the third part of the workshop is conducted.

**Figure 4. One of the workshop facilitators explaining the future scenario part of the workshop.**

As inspiration for future strategies to implement biobased colours, we provided the participants with the sustainable design cards, SDC, (Ræbild & Hasling, 2017, 2019). The SDC's explain different sustainable strategies e.g., re-use, upcycling, and user understanding. In addition, we had prepared posters, where the participants could write down their future strategies; each participant had to imagine three future scenarios. In figure 5, two participants are discussing chosen SDC's and how they can imagine a future of biobased coloured products in their company.

**Figure 5. Two participants filling out the future scenario posters using the sustainable design cards as inspiration.**

After the participants had registered future scenarios, we asked them to place the posters on the timeline and envision when they think their strategies could be implemented between 2022 and 2052. This activity led to a discussion on why the participants placed their scenarios, where they did, as shown in figure 6.

**Figure 6. Discussion on the imagined future scenarios placed on the timeline between 2022 and 2052.**

## Insights from the workshop

The following paragraph depicts relevant insights that the workshop has supplied. The accumulated insight is grouped as following; missing transparency, need of storytelling, challenge in future thinking, and knowledge sharing.

### *Missing transparency*

The first part of the workshop showcased that the participants attain a diverse range of engagement and knowledge regarding their product's coloring processes. *Participant 2* works with deadstock; the textiles are sourced from many producers and thus vary in how it is produced and which colouring methods are applied; Participant 2 express: *"I do not know enough about the colouring methods applied. As a small company, it is hard to find out how the textile is produced, whereas bigger companies have more control and capacity in knowing about this process*." (Own translation from Danish to English) In the case of Participant 2, As Participant 2 explicate, it is problematic that there is no transparency regarding information about which dying method that has been used on dyed deadstock. Such a transparent system that presents which substances that are applied during the coloring of products, could provide an equal opportunity for both smaller and larger companies in choosing between conventional colour or biocolorants.

Participant 3 works with handmade silk scarfs and has visited the production company that dye the textiles in India. This visit had assured the participant of the colouring process and it has given a deeper understanding of which colours that are applied when dyeing the textiles. In this case, it was possible for the participant to obtain clarifying knowledge concerning the dying process of their products; this was possible because of the participant's capacity to visit the production site, as well as them working with a supplier that was willing to invite and show their process.

### *Need for Storytelling*

The second part of the workshop disclosed the need for storytelling of how biocolorants are applied to the modern dye processes and how the colour appearance changes over time. In general, the participants were not very flexible in accepting the change of colour in our proposed colour samples shown in figures 2 and 3. Their acceptance of colour change depended on how the colour faded, as well as the comparison between other products. It appeared that the colour samples which we introduced were not specifically addressed as being bicolored samples which urged the need for storytelling.

Participant 2 addressed the need for storytelling to accept the change in colour over time. According to Participant 2 "*a careful and deeper understanding of the origin of the dyes and impact on the products change of colour would be needed*" ... "*the issue is when you compare products e.g., conventional dyes with biobased. The storytelling should be part of the marketing strategy and thereby I would more easily accept that the colour of a product would fade over a year.*" (Facilitators field notes).

According to Participant 1, "*the storytelling is important and can lead to accept of colour change.*" (Own translation from Danish to English)

The acceptance of fading biocolorants would, according to both participants, deeply depend on the storytelling to be implemented in their company strategy.

### *Challenge in future thinking*

The third part of the workshop highlighted the difficulty of the participants in widening their own business strategy with biocolorants, when creating probable future-scenarios. The timeline started from 2022, which obliged the participants in relating their future scenarios to the very-near future (2022 – 2032), see figure 7. The use of the SDC's helped the participants in guiding their future scenarios. Before the workshop, we had preselected the most relevant SDC's for the participants, however, it was found that we should have narrowed the selection even more, as this might have sharpened the discussion within the given timeframe of the workshop.

**Figure 7. Outlined future scenarios.**

The participants created scenarios involving *small scale production*, *local communities* and *designing with layers* which made the textile fade differently over time. In hindsight, it would have been interesting to see if an introduction to current textile fading methods such as the earlier mentioned Textile Garden, Fibershed, the Living Colour Lab, could have sparked the inspiration of the group allowing a wider future thinking with biocolorants.

### *Knowledge sharing*

Overall, the workshop with the small Danish lifestyle companies showed that all the participants were eager to share their information about their supply chain, while still acknowledging within what areas they lacked information. They were all extremely interested in learning more about biocoloring methods and could see potential in involving their companies with biocolourants if the method improved regarding open access and knowledge sharing. In the reflection on the workshop, we discussed the importance of sharing information, and communicating the knowledge in a way that lifestyle companies find useful and have easy access to.

## Conclusion

In this study, we explored how small Danish lifestyle companies within the textile sector viewed their (i) current product lifetime system for a colored product, (ii) evaluated on faded biocolorant samples in scale of acceptance, and (iii) how they envision near-future implementation strategies for using biocolorants in their products.

From the discussions during the workshop and our subsequent reflection, we found four emerging themes: The first theme is the *missing transparency* in the value chain; the participants expressed a need for open access and transparency in the textile dyeing sector, as it would make it easier for their small companies to take part in applying sustainable textile dyeing methods to their products.

The second theme is regarding the *need for storytelling*; this theme became especially important in the workshop's registrations of future scenarios as it provided a method to ease the acceptance of colour fading over time.

The third theme, *challenges in future thinking for implementing biocolorants,* showed us a need for the participants to be informed about already existing research to spark ideas that they could apply into their own company strategies.

The fourth theme, *knowledge sharing,* showed that the participants see a need to know more about the applied colouring methods for their coloured products.

Overall, this study emphasises that there is a potential to expand the product lifetime with the use of biocoloured textiles. However, this paper finds that smaller Danish lifestyle companies lack information regarding biocolorants and how they can apply them to their products and production processes.

## Acknowledgments

We want to thank the participants who actively engaged and shared their thoughts on the future of biobased colours for the textile sector. We thank Lifestyle and Design Cluster for helping us reach a relevant audience for the workshop.

# Buy, use, sell, repeat – Resale companies' role in sufficiency-based circular economy

**Linda Lisa Maria Turunen**
Aalto University, Espoo, Finland

**Keywords**: Circular economy; Sufficiency; Resale; Secondhand, Fashion.

**Abstract**: Companies operating in the resale market play a crucial role in circulating pre-used and -owned garments in the fashion market. The global secondhand apparel market is expected to grow three times faster than the global apparel market overall (ThredUp 2023).

Resale and secondhand can be regarded as one of the circular economy initiatives, enabling consumers and society to make do with less. While the extensive growth of the resale market shows successful customer activation in product circulation, it is reasonable to ask whether and how the secondhand companies are also encouraging extended use of garments. This paper examines secondhand companies' marketing practices in the light of sufficiency-based circular economy.

The empirical data collection consists of systematic observations from the resale context. First, the secondhand market and business models were mapped. Then, the offerings, marketing practices and consumer engagement of secondhand companies were examined. Ethnographic data was collected for 6 months: 11/2022 – 04/2023, both online and offline in Finland.

Preliminary findings show that secondhand companies offer a wide spectrum of activities that both support and hinder circular economy practices and sufficiency. While the increase in services offered for consumer-sellers has increased the prices of used items, it has simultaneously brought the merchandising and communication practices closer to the traditional fashion market and linear logic. The increased servitization has enhanced attractiveness and convenience. From sufficiency perspective, the main concern is whether the current marketing practices multiply the owners and decrease the usage times instead of celebrating the reuse and longevity of garments.

## Introduction

Companies operating in the resale market play a crucial role circulating pre-used and -owned garments in the fashion market. The market is expected to grow three times faster than the global apparel market overall, reaching €327B by 2027 (ThredUp Report 2023)

Resale companies – secondhand platforms, consignment stores, flea markets and marketplaces – have successfully attracted customers to circulate their used items by offering ease, convenience and security for transactions. Despite having different operating and revenue models (Turunen & Henninger 2022; Turunen 2022), the underlying aim remains the same: their businesses depend on facilitating the interface where the supply and demand of previously used items meet. While aiming to keep the products and materials in circulation as long as possible, the resale logic inherently aligns with the circular economy (EU 2022).

The circular economy requires a variety of stakeholders across the value chain (Niinimäki 2017), and resale can be regarded as one of the "circular economy initiatives, which depending on application, can enable consumers and society to make do with less" (Bocken & Short 2020, p. 3). That said, the extensive growth of the resale market raises the question: does the increasing transactioning extend the use of clothes, replace the primary production or slow down the consumption cycle, or has the resale market turned into an additional channel to circulate items for the sake of profit?

Used clothing can be regarded as a more sustainable alternative if it replaces the purchase of a new item (Klepp et al. 2020). Yet, Laitala and Klepp (2021) suggest that secondhand products may have even fewer usage times compared to brand-new items. This can be attributed to quick decision-making in the context of unique and cheap secondhand treasures, or social pressure emerging in online secondhand shopping situations (Xu et al. 2014; Herjanto et al. 2016).

Successfully facilitating the transactions of used items requires the operations a reverse supply chain (Beh et al. 2016). It requires both the consumer's interest in disposing of attractive possessions and customer acceptance and interest in previously used items. The extensive growth of the resale market shows successful customer activation in product circulation, which also has the potential for a negative rebound effect and an increase in overall consumption (Iran & Schrader 2017; Armstrong & Park 2020). This paper analyzes the business practices of resale and secondhand companies in the light of sufficiency-based circular economy.

## Sufficiency, circular economy and secondhand

Circular economy has regarded one pathway to sustainability. The extensive usage and creative applications of the circular economy have generated interpretations and diverse practical advancements among companies. Circular economy is built upon resource efficiency, such as slowing down or closing the loops; however, Bocken, Niessen and Short (2022) remind us that possible negative rebound effects have been largely neglected.

The value of previously used items has often been justified from a product perspective: a previously used item can be regarded as a more sustainable alternative when compared to something new. Fewer natural resources are needed if previously used item is preferred over new (e.g., Sandin & Peters 2018; Klepp et al. 2020). The relative environmental impact will decrease, the longer the lifespan of the garment and the more it is used (Levänen et al. 2022). This highlights the product-focused approach but neglects the possible rebound effects occurring at the consumption level.

The sufficiency concept is often discussed in the context of consumption (Gorge et al. 2014). Alexander (2012, p. 8) summarizes the concept as "Enough, for Everyone, Forever", which inherently calls for actions from both consumers and companies to keep the consumption–production balance within planetary boundaries.

When approaching the sufficiency concept within the circular economy, Bocken, Niessen & Short (2022, p. 3) suggest that a sufficiency-based circular economy should *"encourage citizens to make conscious consumption choices for sustainability, by making do with less, avoiding unnecessary purchase, repairing and maintaining existing products and buying secondhand, refurbished or remanufactured where possible, to the effect of reducing overall resource use."*

At its core, sufficiency criticizes persuasion to consume beyond need and emphasizes activities that assist consumers in using goods for longer periods (Bocken et al. 2022). In a growth-driven economy, current business practices are often profit oriented. Marketing can be regarded as a tool to create and maintain customer relationships (Gossen et al. 2019, yet it is often accused of stimulating overconsumption (Peattie & Peattie 2009).

This paper examines the marketing practices of secondhand companies, and whether and how they encourage customers towards sufficiency. Secondhand companies are dependent on consumers, both consumer-sellers and their disposal practices, and consumers who prefer buying used items (Turunen et al. 2020). Furthermore, secondhand companies are also dependent on primary operating fashion firms that produce garments.

## Methodology

Empirical data collection consists of ethnographical observations from the resale and secondhand context in Finland. Ethnographic observations were collected both online and offline contexts for 6 months, from November 2022 to April 2023. Data collection was guided by the following questions: 1) What kinds of companies are facilitating the secondary market, how do they operate? 2) What are their offerings, business practices and forms of consumer engagement and interaction?

Based on the guiding questions, the exploration started on business model mapping of secondhand companies. Then, the systematic observations of the offerings, marketing practices and consumer engagement were collected. For example, the services, brand and product selections, pricing, merchandising, and marketing communication of secondhand companies were examined. Both buyers and consumer-sellers –perspectives were included in exploration.

The observations were analyzed by the means of content analysis: the collected data consisted of field note observations, pictures, and screenshots, which were first compiled in one file. Similarities were coded, and restructured to categories, finally the structured observations were interpreted against the theoretical underpinnings of sufficiency-based circular economy.

## Preliminary findings

The company exploration provided structured understanding of business models and operational strategies in the market of previously used fashion items.

To structure the main differences between resale operators' offerings, the models were positioned according to two axes: 1) perceived value for secondhand customer (convenience/affordability); 2) operational context (online/offline). The former related to level of servitization which may influence on both convenience and affordability, and the latter determined the reach and availability of potential new product-owners. See figure 1.

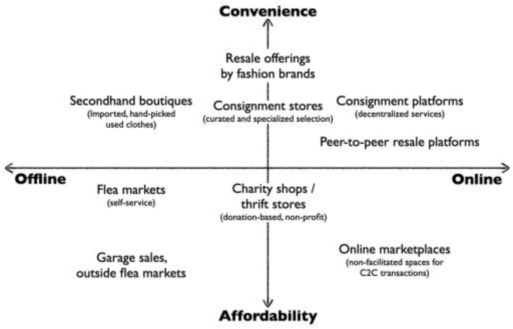

**Figure 1. Convenience for secondhand customers. Companies orchestrating secondhand market.**

While the ease and convenience increase from the perspective of secondhand buyers and consumer-sellers, the company also receives a higher revenue share for orchestrating the service. Thus, higher prices of previously used items can be observed in servitized secondhand offerings. For example, product prices are noticeably higher in decentralized consignment platforms and curated secondhand stores compared to donation-based charity stores or flea markets.

The secondhand company's business model influence on the marketing communication, product selection, and merchandising. The preliminary findings of ethnographic observations revealed that the level of services appears to commercialize the process by applying traditional fashion merchandising practices to attract buying customers. Next the marketing practices of secondhand companies will be reviewed and examined.

### *Marketing communication*

The marketing communications of secondhand companies primarily targeted buying customers. Channels included company webpages, targeted online advertising, influencer marketing, and company accounts in social media platforms (with a reach ranging from several hundreds to tens of thousands of followers).

Most of the marketing messages appeared on social media platforms (own media), and the content can be roughly divided into four categories: 1) informative content (new items, sales); 2) call-to-action (direct links to make purchases); 3) inspirational content and community building (tagged content showcasing treasures, styling tips); 4) educational content (guides how to sell, evaluate quality, tips for slower consumption).

Most direct marketing messages were related to purchase situations or encouraging disposals. The inspirational styling and educational content were often part of influencer collaboration.

Some secondhand companies extensively used basic facts (e.g., resource savings when purchasing secondhand) as an encouragement to shop for previously used items. Information about Co2 and water savings per item or textile waste were the main issues typically shared. However, using calculatory and general statements without careful consideration brings the messages close to the greenwashing dilemma. While the facts bring a sense of conscientious shopping, they do not provide the audience with the information that the calculations are accurate only if the previously used item replaces the purchase of something new.

### *Pricing and product selection*

The most accessible prices appeared in donation-based charity shops, but also in traditional flea markets, where the consumer-seller pays only the booth rent and/or a small sales provision (less than 20% per garment). If the product remained unsold, consumer-sellers often applied price reductions. In decentralized platforms price reductions were built-in, such as a price reduction every 3-5 weeks until the sales period ends. Donation-based operators offered the heaviest discounts, which usually preceded the arrival of new collections or seasons. During sales, the opening hours were extended, and the floor was constantly restocked as it became emptier.

Some flea markets and decentralized platforms offered to take care of unsold items by shipping them to charity. This demonstrates how different secondhand companies are interconnected and how unwanted clothes are circulated. The donation-based operators did not disclose where the unsold items were directed.

Psychological pricing tactics, such as 12,90€ or 9,90€, were mainly used in decentralized platforms and some consignment stores.

Both flea markets and donation-based stores had the greatest variety of different brands, products, and quality, ranging from ultra-fast fashion pieces to vintage gems. Consignment stores, certain branded flea markets and decentralized platforms had rules and/or suggestions regarding the brands, condition and resale price allowed for sale. This homogenization of product selection and pricing may provide convenience and trust for buying customer, but it also brings the entire market closer to the logic of a traditional fashion store.

Furthermore, to meet the demand, especially in decentralized platforms and curated secondhand stores, consumer-sellers were advised to bring seasonal and currently fashionable clothes. In decentralized platforms and flea markets, consumers were required to sell multiple items at the same time, which was not the case in C2C platforms. These rules and recommendations streamlined the offerings. Consignment models and resale offerings by fashion brands added a sense of premiumness to the secondhand context, with more expensive, slightly used items, high quality and premium brands, and convenience for purchase situation (compared to treasure hunting).

### *Merchandising*

Traditional fashion merchandising practices were identified in secondhand companies. Brick-and-mortar stores (with the exception of traditional flea market) employ visual merchandising and window displays to attract visitors. The items are rotated on the floor to create a sense of newness with each visit. In the flea market model, the change days were unfixed, which created rotation, and made it possible to have something "new" several times a week.

The business model defined the floor plan in physical stores. Flea markets had a rent-a-rag approach (typically for 1 week) and offered wardrobe experience for buyer. In donation-based shops the categorization was based on the type of item, sizes, colors, vintage, or newness, enabling customer to make need-based visits. Similarly, curated consignment stores often followed the product-type categorization but enhanced the experience with specific style and brand selection.

Some platforms and online stores had both functions: search could be done by size, type, color, brand (especially in decentralized platforms), or by viewing all the pieces the consumer-seller had (especially in peer-to-peer platforms). Depending on the model, the online context offered either a product-centered (decentralized platform) or a human-centered approach with the possibility for interaction and more personal transactions (peer-to-peer platforms). These aspects bring fluctuations to the service experience, diversity for services and levels of interaction that are suitable for each customer.

Furthermore, some platforms also offered notification possibilities, which made pre-considered purchasing easier and possibly reduced explorative browsing.

The level of services and operation models also brought differences in the available product information. In physical stores, the product itself, accompanied by a price tag, was the source of information. In the online context, product information consisted of pictures and additional descriptions. Some platforms offered condition assessment, description of fit, material content, measurements, and multiple pictures from different angles, while others had only one picture from the front and basic information, such as price, size, brand, and color.

Textual descriptions accompanied with visual product presentations. Most of the examined platforms presented the item laid on a surface or hanging on a hanger, while presenting the item on a torso was less common. Merchandising decisions of platforms do not seem to support informed purchase decisions, especially if product descriptions are incomplete.

Further, there is no return possibility if a used item is bought from physical secondhand store. Some decentralized platforms offer a return possibility, but in case of a return, the buyer receives store credit. Facilitated peer-to-peer platforms ensure transaction safety and apply a return policy only if the product differs from the description.

## Conclusions

Secondhand companies encourage consumers to circulate unwanted items and make used items desirable. Developing efficient reverse supply chains and infrastructure to enable a well-functioning market is paving the way for the extended use of existing items.

This paper focused on secondhand companies and their marketing practices, but as the secondhand market is a reflection of the primary market, it should be seen as part of an ecosystem rather than a separate entity. It is dependent on the items produced for the primary market. Thus, the circulation of (ultra)fast fashion may bring a few more uses for a garment but does not make the item sustainable.

In addition, the findings show that resale and secondhand operators are applying merchandising practices familiar to the fashion field. Scarcity and a sense of urgency, constant newness, and cheapness were uncovered from marketing communication and merchandising practices applied in both online and offline contexts. On one hand, secondary channels turning into an alternative and attractive channel of purchase is a positive development. On the other hand, the findings show a lack of active encouragement for slowing down or reducing consumption – instead, even increasing speed and pushing for impulse purchases through fashion merchandising applications.

A well-functioning resale market requires the participation of different stakeholders. To build a sufficiency-embracing future for the secondhand market, several aspects need to be covered. First, sufficiency-based circular economy depends on the products: Are the products circulating in the secondary market suitable for multiple owners and long-term use? Second, the services that enable the circulation of reusable items need to encourage sufficiency rather than overconsumption. Third, consumers need to be educated and encouraged to practice conscious consumption.

Secondhand companies are taking steps towards sufficiency by lowering the barriers to purchasing previously used items and conveniently circulating unwanted items. While the secondhand market is becoming more professionally facilitated and moving towards traditional fashion merchandising, it is worthwhile to shift the focus to longevity and extended use rather than the attraction of resale practices.

# Reuse and repair ecosystems: analysis of the emergence of the tensions between the stakeholders

**Benjamin Tyl[a], Aude Pottier[a], Romain Allais[a]**
a) APESA, Pau, France

**Keywords**: Ecosystem; Repair; Reuse; Tension; Focus group.

**Abstract**: Reuse and repair are major issues to move towards sustainability. One of the strategies to foster the development of these structures is the mutualisation of resources and activities (facilities, employees, partnership, volunteers, etc.). This research focuses on the development of reuse and repair ecosystems, emerging from a multi-partner logic, whose intention is to create mutual values and to collectively carry the costs and benefits. It relies on a concrete case study, the Ïkos project, a reuse and repair ecosystem under development in Bordeaux, France. This paper aims to deepen knowledge on tensions related to the governance and the different logics of value creation deployed by the stakeholder all along the development of an ecosystem. "Tensions" is the translation of potential conflicting interactions between the stakeholders of a project. The methodology is a literature review of tensions related to the development of circular ecosystems, a macro analysis of these tensions through the development of focus group with external experts to validate and complete them, and a micro analysis through the Ïkos case study. Some results have emerged. Two sets of tensions have been identified and challenged: tensions of appropriation (of social, environmental and economic value) and tensions related to the development of ecosystems (value creation versus value capture, mutual value versus individual value, gaining or losing value). Two other tensions have been added (temporal and interpersonal tension). In conclusion, this work on tensions based on the experience of various socio-professional profiles has been put into perspective by the Ïkos project.

## Introduction

Amongst strategies to move towards sustainability, reuse and repair workshops are key organizations of the circular economy that promote resource valorization while creating local activities. However, they face many obstacles: unsustainable business models, negative perception amongst public actors or competition with the recycling sector (Gobert et al. 2020). One of the strategies to foster the development of these structures is the mutualisation of resources and activities (facilities, employees, partnership, volunteers, etc.) through the creation of territorial ecosystems.

### *Ecosystems and circular economy*

Konietzko et al (2020) characterize and map ecosystems as follows: (1) They consist of multiple locally, regionally, or globally distributed entities that are not owned by a single organization; (2) They involve dynamic, collaborative and competitive relationships between actors; (3) They involve flows of data, services and money; (4) They often involve complementary products and services; (5) They evolve as actors constantly redefine their capabilities and relationships.

The objective is to create, and capture, value from a set of innovative activities, structured in a collaborative manner, which evolves based on an initially constructed value proposition (Adner, 2017; Ritala et al., 2013; Jacobides et al., 2018, De Vasconcelos Gomes et al., 2018). Therefore, the establishment of repair and reuse ecosystems combines two key elements: the development of a system (1) that goes beyond the boundaries of a single organization and (2) that integrates sustainability issues. This type of new structure cannot be conceived as a "stand-alone" model but requires revisiting the business model that goes beyond a classical one.

### *The Ïkos project: a repair and reuse ecosystem*

This paper is related to Ïkos, a French case study of repair and reuse ecosystem initially created by 5 founding members; operating in the second-hand product value chain (collect, sorting, sale).

Located in Bordeaux (France), this place is qualified as a "village" in a strategy of differentiation from the existing repair and reuse workshops. In fact, from a social and environmental speech, Ïkos offers local residents and consumers access to a complete range of second-hand products through a shopping mall that brings together the products collected and sometimes re/up-cycled by the members of the collective (Ïkos tends to collect and process 12,000 tons of waste per year). It also promotes to bring together the different activities of its members within the same place: from production (i.e. sorting and processing center), sales of second-hand or upcycled products, pedagogical activities to foster customers' behaviour change and development of new activities such as research activities on repair and reuse.

A first research-action project, described in Tyl and Baldacchino (2019), questioned how to identify new activities/synergies that can be created through the development of Ïkos, to favor a territorial anchoring of the ecosystem and to develop Ïkos' economic and social business model, with a specific focus on the governance of the project.

Next section summarizes previous results on Ïkos analysis and present a state of the art on circular ecosystems, leading to our research question focused on tensions between actors and on our research methodology. We then present the result of our research, i.e. an analysis of theses tensions. This leads us to some conclusions and perspectives.

## From ecosystem analysis to tensions identification

### *Previous works on Ïkos*

From a first research-action project (Tyl and Baldacchino, 2019), three main feedbacks emerged, following a dialogical approach (i.e. a set of antagonistic but complementary issues (Morin, 2007), re-called "tension" in this paper) (see fig.1):

(1) the difficulty to develop a collaborative project and to go beyond individual organizations, each project holders having their own business models or activities, with different statutes (form NGO to companies), and different time pressure (i.e. some project holders have to quickly enlarge their area of production)

(2) the different positions of each project holders in the reuse/repair value chain, between B-to-B actors (collect of Waste) and B-to-C ones (sales, citizen workshops)

(3) the difficulty to mix public and private actors point of views.

Therefore, from this first work, we showed that the development of a repair and reuse ecosystem can create tensions among actors.

### *From previous results to a state of the art on tensions related to ecosystem development*

During the development of ecosystem, the question is no longer to identify the value proposition of a single organization through the marketing of a product or service, but to understand how the global offer proposed by the ecosystem complements the individual proposal, and how it can provide a superior "circular" value proposition (Konietzko et al. 2020). Therefore, the development of ecosystems can be understood through the development of collaborative mechanisms (Hellstrom et al. 2015). These collaboration mechanisms become an important element in the development of economic and social models that extend beyond the boundaries of the company and that involve the understanding and consideration of a broader ecosystem (Hellstrom et al., 2015). One of the major challenges is to align the individual actors' objectives with the ecosystem's interests. From these alliances, collaborative economic models will arise, making it possible to create, capture and offer value to customers/users.

The opening of the company's borders generates tensions in the capture and appropriation of value within ecosystems. <u>This paper aims to deepen knowledge on these tensions.</u>

### *Methodology*

To validate and reveal these tensions, we have developed a three-steps process during the research project.

A first step has consisted in a literature review on tensions emerging during the development of ecosystems in the context of circular economy, as well as associated tensions.

The second step was to perform a 2.5 hours focus group with practitioners (i.e. social economy project holders, coaches, public actors, head of the regional recycling network) to discuss main tensions identified in literature.

The third step consisted in analysing the Ïkos case study in regards to the tension issues. The analysis was based on a geographical approach (semi-structured interviews and focus groups with members of the collective and project partners) in order to understand the political context and the territorial integration of the project and the constitution of the Ïkos collective through the values and visions of its members. An economic entry was also developed via a protocol incorporating the logic of project support generating externalities and a methodology for analysing impacts and dependencies.

## Tensions exploration and revelation

### *Tensions in circular ecosystems development, a state of the art*

Each actor must be able to position himself on the value he can obtain from the ecosystem and whether this is sufficient for him to determine whether he can remain active in the ecosystem (Oskam et al. 2021). It is therefore necessary to broaden the analysis of ecosystem value by studying the tensions that may arise as the ecosystem develops. The literature allows us to distinguish two main types of tension:

1. Tensions that arise when there is a dissymmetry between the object that creates value and the object that appropriates it (Ritala et al. 2021). This dissymmetry can be from an environmental, social or economic point of view.
2. Tensions directly linked to the development of the ecosystem. Oskam et al. (2020) identify three sources of tension related to ecosystem development.

- Tension 2.1. Value creation versus value capture.

A difference can emerge between value creation and value capture, which evolves over time as a value proposition becomes clearer. This tension can be identified in particular in the context of the asymmetries identified in the previous paragraph.

- Tension 2.2. Mutual value versus individual value.

Value creation often takes place at the ecosystem level, while value capture often takes place at the actor level. Each actor must also be able to take advantage of the value created by the ecosystem, by adapting its business model. This creates a tension, as all actors in the ecosystem must contribute to the mutual value but also ensure that they benefit individually.

- Tension 2.3: Gain or lose value.

A third tension arises from differences among actors in their perceptions of what is valuable and who benefits from value creation, a process referred to as "value shifting" (Lepak et al., 2007 cited in Oskam et al. (2020)). While tension 1 concerns the ability of ecosystem actors to create as well as capture value, tension 3 concerns whether actors perceive the division of captured value among actors to be fair.

### *A practitioners' view on tensions*

Each tension identified in the literature was confirmed by the set of participants regarding their own experiences. Two additional tensions emerged during this focus group.

- Interpersonal/representation tensions

Fundamental differences in the representation of the world can appear between the actors of the same structure and within ecosystems. The actors participating in an ecosystem must be able to formalize their representations of the world, not to align them, but to be able to discuss their points of view, and to build common rules within the ecosystem, such as the methods of funding, the inclusion in a market or non-market economy or even the legal and institutional framework.

- Temporal tension

The temporalities of the actors are different and can be the source of tensions. It particularly appears between the project holders and the local authorities. This temporal tension is expressed through decision-making or study processes, but also during elective deadlines. It is also linked to political orientations that may vary, as local authority staff can provide the continuity necessary for the good vitality of an ecosystem.

Therefore, regarding the state of the art and the practitioners' focus group a set of tensions related to the development of an ecosystem is proposed (table 1).

| | | |
|---|---|---|
| Tension of appropriation | env. | Tensions can arise by diluting environmental aspects in favor of social and economic aspects (overexploitation of natural resources, overconsumption or overproduction, etc.). |
| | soc. | Tensions can arise by diluting social aspects to the benefit of environmental and economic aspects (privatization of public goods, corruption or lack of transparency, abuse of aid, etc.) |
| | eco. | Tensions can arise by reducing the appropriation of social and environmental values by economic actors (private interest to the detriment of the common good, information sharing) |
| Tension linked to the development of ecosystems | Value creation vs. value capture | Contributing to value creation does not necessarily result in value capture, the tension comes from the fact that value creation can be done at the ecosystem level while value capture is at an individual level |
| | Mutual value vs. individual value | The tension arises from the fact that each actor must be able to benefit from the value created by the ecosystem by adjusting its individual business model. All actors in the ecosystem must contribute to the mutual value through their collaborative efforts, but also ensure that they benefit individually |
| | Gain value or lose it. | Tension can arise because some actors may try to appropriate too much of the value, which other actors in the ecosystem may consider unfair |
| Interpersonal / representation tensions | | Tensions may arise between ecosystem actors, at an individual and personal level, who do not share the same common values |
| Temporal tensions | | Tensions can arise when ecosystem actors have an agenda that differs too widely. This is particularly the case between private and public actors. |

**Table 1. Description of tensions**

## Confrontation of tensions with the Ïkos case study

This work made it possible to find the tensions that emerged in a real case study and to confront it with the tensions previously identified.

- **The tension linked to the model of development and economic balance:**

The nature or localization of the reused waste deposit are strongly structuring factors in the activities of the various partners. However, in the development of a sustainable and common economic model, we observe the absence of a systemic approach and a real questioning of the project. The external support (legal and financial set-up) makes it possible to go through a formalized stage (legal statutes, loan, search of external funding, etc.) and to develop a real approach around a strategy and an operational and common economic organization.

- **An internal tension around values:**

A common vision appears around the values of the social economy (limited profit-making, democratic and non-vertical management, principles of solidarity and responsibility of actors, etc.) but the generality of these values opens the way to different interpretations and priorities depending on the project leaders. The lack of formalization and clarity on the values, vision and underlying objectives of each of the project holders creates a vagueness that creates ambiguities and potential sources of current or future conflict.

- **A tension linked to the relationship with public actors**

If there is a common objective to be emancipated from the decision-making of public authorities, this does not necessarily imply a questioning of access to public subsidies or agreements, demonstrating an ambiguity of the private/public links. Some barriers can be identified between the project holders of the ecosystems and the local public authority: different time frames between the project issues and the political decisions making chaotic the development of the project, the complexity of public skill levels and funders leads to misunderstandings / expectations that can lead to delays, the no-transversal work between public services making it not possible to respond to the project progress needs, etc.

- **A tension relates to the governance and legal status**

The integration of new partners, external stakeholders, inhabitants is still an area of tension to be worked on and that must be formalized within a legal status: Should the "citizen" stakeholder be separated into several distinct categories: users, employees, residents? Should each be included separately in governance? Is the integration of the public actor into the project governance only a variable of economic adjustment in a project with a strong political and social impact? What kind of sustainable relationships can be created?

## Conclusion

This communication aims at deepening the tensions that may emerge during the constitution of repair and reuse ecosystems. Tensions identified in the state of the art have been confronted by practitioners' experiences Two additional tensions enrich the literature: interpersonal and temporal tension.

Tensions have also been identified in a case study in France, a repair and reuse village, Ïkos. This case study has illustrated some tension, and, above all, highlights the way in which these tensions are hybridized in the face of the challenges of the project leaders. The internal tension linked around values is clearly linked to the interpersonal tensions, i.e. the risk of misunderstanding between project holder and the difference vision of the project. It also illustrates the tensions of appropriation, as project holders do not have the same initial values and can appropriate value according to their interpretation of the project. The tension linked to relationship with public actors refers to temporal tensions as economic actors – project holders- do not have the same temporal constraint that public actor, so that their calendar does not meet. It also illustrates the fears around a politicized appropriation that has become out of control of the project.
The tension linked to the model of development and economic balance reflects those relating to the sharing of value between the collective and the individual and raises fears about the appropriation of added value by certain actors. This subject comes to activate interpersonal tensions. The tension relates to the governance and legal status constitutes a receptacle for all the tensions by seeking each of the inputs. By constituting the translation of the project, this theme draws on both the tensions of appropriation and those relating to the development of the ecosystem. Temporality as well as the bearing of common values are also confronted with this stage.

This paper is the presentation of partial results of this research project. Some tools have been analysed to support project holders when they face with these tensions, and a global methodology to support ecosystem development has been proposed. Future works will consist on a consolidation of the set of tensions in other real case studied (circular economy ecosystem) and to better understand how to manage tensions when they are hybridized.

## Acknowledgments

The authors wish to thank the French national agency ADEME for its funding of the TERROIR project as well as the IKOS members.

# The Emerging Landscape of Urban Upcycling: identifying manifestations in a city context

**Marco van Hees** [a,b]**, Inge Oskam** [a]**, Nancy Bocken** [b]
a) Centre of Expertise City Net Zero, Amsterdam University of Applied Sciences, Amsterdam, The Netherlands.
b) Maastricht Sustainability Institute, Maastricht University, Maastricht, The Netherlands

**Keywords**: Upcycling; Circular Cities; Solid Waste Management; Furniture.

**Abstract**: Upcycling has been embraced by circular economy enthusiasts, policy-makers and collaborative initiatives across Europe. Early studies describe upcycling as a concept aimed at resource conservation by keeping products, components and materials at their highest potential value across consecutive product lifecycles, with zero-negative or even potential positive impact on the natural environment. Similarly, more recent literature on the circular economy views upcycling as a strategy to slow and close resource cycles through product life-extension approaches, such as reuse, repair, refurbishment, remanufacturing and repurpose. With growing environmental concerns, upcycling has become a re-emerging theme in literature and practice. Cities offer opportunities for an increasing number of upcycling initiatives, but little is known about what manifestations of upcycling occur specifically in urban areas or how these urban upcycling initiatives emerge. For example, so-called Urban Resource Centers seek to tackle challenges in urban solid waste management by encouraging entrepreneurs to create value from local waste streams. Therefore, our objective is to address this literature gap and explore manifestations of upcycling in a city context by means of qualitative research, following a case-study approach based on data collected from research archives and 17 preliminary interviews with entrepreneurs and experts in urban upcycling of furniture and interior design products.

This study contributes to a structured overview of urban upcycling initiatives and the internal and external factors that drive entrepreneurial initiatives and development. Future work will build on this study to make urban upcycling initiatives more widespread and impactful to deliver on their environmental and social goals.

## Introduction

In the face of climate concerns and increasing levels of waste, upcycling is becoming an ever more important theme (Cooper, 2021; Sung et al., 2019; Singh, 2022). In this section we first introduce the concept of upcycling, next we explore upcycling in an urban context and finally we zoom in on upcyling in the furniture industry.

### *What is upcycling?*

Definitions, benefits, and various types of upcycling have been explored and identified in a structured literature review by Sung (2015), who observes that scholars have struggled with a proliferation of definitions of upcycling and proposes that upcycling aims at creating or modifying products from waste to products of higher quality or value. However, other scholars propose more broader definitions of upcycling and suggest that upcycling processes, strategies and principles can also aim towards maintaining value, for example by prolonged usage, and consider adding new intangible elements, such as functionality or services, also as a means for upcycling (Luedeke-Freund et al., 2018; EMF 2012; Braungart et al., 2007).

Whether an activity can be called upcycling or downcycling depends on the resulting value and quality after modification of waste resources (Sung, 2015; Sung et al., 2019; Luedeke-Freund et al., 2018). For example, recycling is generally associated with sustainability by the public and is getting more attention in literature, but it is often not the most preferred circular strategy as it still requires significant energy inputs and leads to degrading material quality (Allwood, 2014). Therefore, in most cases, recycling is downcycling.

Industrial upcycling was introduced in sustainable industrial design literature by

Braungart and McDonough (2007) and further popularized through best-selling business publications, design tools and documentaries advocating the cradle-to-cradle principle. Cradle-to-cradle uses nature as a metaphor to advocate that all industrial material should be re-used at its highest potential value and that toxic waste material should be designed out or kept separated from the natural environment in closed loops (Braungart & McDonough, 2007). The cascaded re-use of human-made material and the separation between the technical cycle and the biological cycle were introduced as key principles for the circular economy (MacArthur, 2013) and the cradle-to-cradle principle was positioned in literature as an example of create-value-from-waste sustainable business model archetype, along other related concepts, such as circular economy, industrial symbioses and recycling (Bocken et al., 2014).

On the other hand, humans have been creating new objects from previously used material for thousands of years. This type of upcycling, which is referred to as 'individual upcycling' and often entail individual creative or small-scale entrepreneurial initiatives, may even have more benefits and higher potential sustainable impact than industrial upcycling but has gained relatively little attention in literature (Sung, 2015; Singh et al., 2019).

### *Urban upcycling*

The city provides important context conditions required to face major challenges in a transition to a circular economy (Prendeville et al, 2018; Barbero & Pallaro, 2018; Arsova et al., 2022). At present 55% of the world population live in cities and this number is expected to grow to 68% by 2050 (UN Habitat, 2022). This unprecedented growth of metropolitan regions, which often extend beyond national governmental and geographic boundaries, offer opportunities for developing and scaling up circular initiatives (van Winden van et al., 2017; Prendeville et al., 2018; Raven et al., 2011). As city research has been focusing more on energy and recycling by urban mining, which mostly entails downcycling (Arora et al., 2020; Gutberlet, 2015; Brunner, 2011), this has left an interesting research gap for urban upcycling.

Although urban regions only cover 2% of the global surface, cities are important and fast-growing clusters of human activity that account for 70-75% of global resource consumption, 50% of global garbage generation and 80% of global energy usage. (Birgovan et al., 2022; Prendeville et al., 2018). On average, cities produce 76% of global emissions, but if imported consumption-based goods and services are taken into account, carbon emissions for cities in industrialized countries are much higher (Sung et al., 2019).

This cross-national fast-growing concentration of consumption, waste generation and energy usage will increase organizational and environmental challenges for urban solid waste streams but may also create new opportunities for accelerating and scaling up upcycling initiatives. Therefore, urban areas provide an important space for action.

### *Upcycling in the furniture industry*

Furniture and interior design products constitute an important urban waste stream accounting for nearly 50% of total solid waste in European cities with a total of 10 million tons annually, largely consisting of wood. Although wood is recyclable material and also relatively easy to upcycle, 90% of the furniture waste stream is going straight to landfill or incineration (Cooper et al., 2021). Its significance in the volume of urban solid waste streams, its financial and environmental impact on urban waste systems and its potential opportunities for creating multiple value in an urban context makes furniture waste streams particularly interesting for studying urban upcycling.

Research on upcycling has largely focused on environmental and financial opportunities and technical feasibility of industrial upcycling, particularly in promising sectors such as the wood, textile, and plastics industry (Singh et al., 2019; Malé-Alemany et al., 2022; Zhao et al., 2022). However, social benefits, financial feasibility and marketability of upcycling have been scarcely explored (Sung, 2015).

As furniture consists of durable products that are technologically not very complex and accounts for a large portion of cities bulky waste, the furniture industry is a promising but under-researched sector (Cooper et al., 2019; Singh et al., 2019).

## Method

This study aims to identify and scope preliminary manifestations of upcycling in an urban context by studying internal and external drivers to engage in entrepreneurial upcycling initiatives connected to urban waste streams and/or urban stakeholders.

Adapted from a combination of definitions of upcycling and urban initiatives in literature (Sung et al., 2019; Luedeke-Freund et al., 2018; Prendeville et al., 2018), we define an urban upcycling initiative as *a new plan or action aimed at re-using or converting discarded products, components or materials into something of higher value, functionality and/or quality in their second life in partnership with the city's stakeholders (citizens, community, business and knowledge stakeholders)*.

As this study is exploratory of nature, we used a qualitative case study approach (Yin et al., 2013) building on interviews with practitioners who are engaged in urban upcycling initiatives. The interviewees listed in Table 1 were selected by means of purposive sampling (Bryman et al., 2011) based on their engagement in initiating and developing urban upcycling initiatives. We applied three additional sampling criteria in order to assure diversity and a broad scope of perspectives. Firstly by including the perspectives of entrepreneurs as well as expert practitioners from local authorities and practitioners in urban waste management. Secondly by interviewing entrepreneurs from business-to-consumer (B2C) as well as business-to-business (B2B) initiatives. And finally by including initiatives that offer tangible products as well as services-focused organizations.

**Table 1. List of interviewees.**

| nr | Interviewee | B2C/B2B | Product/ Service |
|---|---|---|---|
| 1 | Commercial director - furniture refurbishment company | Both | Both |
| 2 | Senior account manager - Waste management company | B2B | Service |
| 3 | Sustainability manager - Interior project producer | B2B | Product |
| 4 | Manager Innovation - Office furniture manufacturer | B2B | Product |
| 5 | Owner/Director - Waste management company | B2B | Service |
| 6 | Founder - Furniture design company | Both | Product |
| 7 | Co-founder - Architecture & interior design office | B2B | Service |
| 8 | Owner & senior designer - Interior products design studio | B2C | Product |
| 9 | Director - DIY store & production studio | B2C | Both |
| 10 | Creative director / Community manager - Online sales platform & consultancy | Both | Service |
| 11 | Founder - Interior products design company | Both | Product |
| 12 | Founder - Interior products design company | B2C | Product |
| 13 | Co-founder - Design studio | B2C | Product |
| 14 | Owner - Design studio | Both | Product |
| 15 | Owner - Interior products design and production | B2C | Product |
| 16 | Founder - Products store and workshops | B2C | Product |
| 17 | Program manager & Senior policy advisor – public solid waste management | Both | Service |

The focus of the data collection and analysis was on identifying urban upcycling manifestations by exploring relevant internal and external factors through which these initiatives emerged and further developed.

First, primary data on relevant factors that drive urban upcycling were collected from seventeen semi-structured interviews of approximately 45-60 minutes with entrepreneurs and experts in urban upcycling (Table 1). 6 interviews were conducted in 2023 and 11 interviews were selected from a research archive of interviews on repurposing conducted by the same interviewer in 2020.

All interviews were recorded, transcribed ad verbatim and stored on research drive with formal consent of interviewees and permission to use collected data in academic research without publication of personal data.

Second, interview transcriptions were imported in MaxQDA for further analysis by means of open coding (Strauss and Corbin, 1990). Internal and external factors that drive urban upcycling were clustered to concepts and themes to identify preliminary manifestations. Finally, as a preliminary step towards further validation with practitioners and researchers in this ongoing research, the sixteen cases were mapped and classified according to the manifestations found.

## Results

By focusing on factors that drive entrepreneurs to engage in urban upcycling initiatives we identified three focal themes and eight manifestations of urban upcycling. These themes and manifestations have been summarized in Table 2, together with some case examples.

**Table 2. Main themes, manifestations and examples of urban upcycling.**

| | Themes | Manifestation | Examples |
|---|---|---|---|
| 1 | Urban upcycling innovation: process, market, product, service | A) Process focused urban upcycling | (1) develops efficient refurbishment technology |
| | | B) Market focused urban upcycling | (9) valorises discarded building material in other market |
| | | C) Product focused urban upcycling | (6) designs and produces tables from discarded oak floors |
| | | D) Service focused urban upcycling | (10) project local repair services for furniture chain store |
| 2 | Urban upcycling entrepreneurship purpose | A) Urban upcycling 'for good' | (8) 'climate-quits' job and engages in upcycling start-up to generate sustainable impact |
| | | B) Urban upcycling 'for income/profit' | (15) discovers opportunity to generate income/profit by engaging in upcycling |
| 3 | Urban upcycling collaboration | A) Urban supply chain upcycling collaborations | (12) outsources upcycling production activities |
| | | B) Urban ecosystem upcycling collaborations | (2) aims to collaborate in product-private partnerships to facilitate urban upcycling ecosystem |

Our findings are based on internal and external factors which have been listed in Tables 3 and 4. Internal factors include the reasons, ambitions, objectives and benefits for entrepreneurs in urban upcycling to engage in upcycling initiatives. External factors are based on contextual conditions and critical incidents mentioned by the interviewees, that were considered supportive for initiating and/or further developing initiatives by entrepreneurs in urban upcycling or by experts in urban solid waste management, but which cannot be directly controlled by urban upcycling entrepreneurs.

**Table 3. Internal factors that drive urban upcycling initiatives.**

| Internal driving factors | Related interview nr. (table 1) | Related theme nr. (table 2) |
|---|---|---|
| Purpose / intended impact | 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 14, 15 | 2A, 3B |
| Learning and business experimentation | 1, 2, 5, 7, 9, 10, 12, 16 | 1, 2, 3 |
| Create a viable business case | 1, 2, 3, 4, 9, 10, 12, 14. 15 | 2B |
| Organisation process improvement | 1, 2, 3, 4, 6, 7, 9, 10, 13, 14, 15, 16 | 1A |
| Customer relationship | 1, 2, 3, 4, 6, 7, 9,11, 16 | 1, 2, 3 |
| Seeking collaboration | 2, 9, 10, 11, 12 | 3 |
| Educate and inspire others | 3, 7, 9, 10, 11, 12, 13, 14 | 2A, 1D |
| Generate public exposure | 1, 3, 10, 11, 13 | 1, 2 |
| Entrepreneurial drive/spirit | 2, 9, 10, 14, 15 | 1, 2, 3 |
| Research & education driven | 1, 3, 5, 6, 7, 9, 10, 11, 16, 18 | 1, 2 |
| Material availability / urban mining | 3, 6, 7, 9, 12, 13, 16 | 1A, 1C 3 |
| Local engagement | 9, 10, 12, 14, 16 | 1B, 2A, 3 |

**Table 4. External factors that drive urban upcycling initiatives.**

| External driving factors | Related interview nr. (table 1) | Related theme nr. (table 2) |
|---|---|---|
| Supportive ecosystem (stakeholder collaborations and partnerships) | 1, 2, 3, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 16, 17 | 1, 2, 3 |
| Availability of resources (quality, traceability, predictability) | 2, 3, 4, 5, 6, 7, 9, 10, 11, 12, 13, 15 | 1, 3 |
| Media exposure that supports positive public perception | 1, 2, 5, 7, 9, 10, 11, 12, 13, 15 | 1, 2, 3 |
| Material supplier involvement | 2, 9, 11, 12, 13, 14 | 1, 3 |
| Sustainable procurement | 1, 2, 3, 4, 5, 7, 10, 11, 12 | 1, 2, 3 |
| Political incentives (legal compliance, taxes, subsidies) | 1, 7, 9, 10 | 1, 2 |
| Proof of concept, inspiring examples and best practices | 1, 2, 3, 5, 6, 7, 12, 13 , 14, 15 | 1 |
| Supportive education system | 7, 10 | 1, 3 |

## Conclusions

Our aim was to identify urban upcycling manifestations by clustering initiatives based on variables derived from internal and external factors that encourage entrepreneurs to start and further develop initiatives in urban upcycling. We have identified eight preliminary manifestations which are related to three main themes: innovation, purpose, and collaboration (see Table 2). However, since the preliminary manifestations in our study have not been validated, we propose further refinement and validation of the themes and manifestations by means of a literature study (see Table 5), and focus group workshops with experts and practitioners.

**Table 5. Themes and examples of relevant literature.**

| Themes | Examples of relevant Literature |
|---|---|
| Urban upcycling innovation: process, market, product, service | Circular business model innovation strategy (Bocken and Ritala, P., 2021) Product Service Systems (Tukker, 2004) |
| Urban upcycling entrepreneurship purposes | Social entrepreneurship (Alter, 2007; Lubberink, 2019) |
| Urban upcycling collaboration | Circular supply chain management (Farooque et al., 2019; Geissdoerfer et al., 2019) Circular Ecosystem Innovation (Konietzko et al., 2020) |

Other limitations of our study include the specific urban context and the sampling criteria used. Although the relation between initiatives and their city context is evident, it remains unclear whether a similar type of relation occurs between manifestations and the urban environment. Therefore, it would be relevant to explore how manifestations are related to a generic urban context, or to a specific city context. For example, it may also be interesting to study whether manifestations emerge differently in various urban contexts, such as cities in various countries within the EU or urban regions in western Europe versus the global south.

Next, since our sampling criteria did not include representation of relevant strategies such as repair, and the repurposing strategy may be overrepresented, we also suggest exploring how manifestations relate to slowing and closing loop strategies for upcycling (Bocken et al., 2016) and to the so-called R-strategies which have been proposed by the Dutch government to minimize resource input and waste (Potting et al., 2016).

Follow-up research could also extend on how various manifestations in an urban context are scaled up towards circular business models and how business models of stakeholders in urban ecosystems related to upcycling interact with each other and with actors in the regime context (Schaltegger et al., 2016; Koistinen et al., 2017).

As a first step in this four-year research project, we aim to validate manifestations by means of an extensive database of urban upcycling initiatives. These urban upcycling examples will be used to test our preliminary classification in additional mapping workshop exercises with researchers and practitioners. After this refinement and validation, the urban upyclcing manifestations can be used by researchers, politicians, entrepreneurs and other practitioners to develop interventions, such as experiments or policy instruments, for scaling up and accelerating urban upcycling initiatives.

## Acknowledgments

This research is co-funded by Regieorgaan SIA (RAAK-PRO), part of Dutch research council (NWO), project Urban Upcycling (RAAK.PRO04.029).

# The influence of a modular design and facilitating cues on consumers' likeliness to repair electronic products

**Renske van den Berge**[(a)], **Lise Magnier**[(a)], **Ruth Mugge**[(a,b)]
a) Delft University of Technology, Delft, The Netherlands
b) University of Amsterdam, Amsterdam, The Netherlands

**Keywords**: Product Lifetime Extension; Repair; Modularity; Design Cues; Sustainable Consumer Behavior.

**Abstract**: Modularity represents a promising design strategy for product lifetime extension. Yet, the fact that products are physically designed to be repaired via such a modular design, does not mean consumers will act accordingly. Past research demonstrated promising results with current modular smartphone users. However, these users may not necessarily reflect the average consumer because modular products are not (yet) the norm. Two experiments were set up to test the effect of modularity on consumers' likeliness to repair and to investigate which specific design cues can encourage consumers to execute DIY ('do-it-yourself') repair. The first study shows that a modular design increased the general likeliness to repair and decreased the task difficulty compared to a conventional design. Interestingly, the likeliness to use professional repair increased for modular smartphones, while the likeliness to DIY repair remained low. For DIY repair, consumers thus may need more support. The second study shows that facilitating design cues on the inside of a modular smartphone increased consumers' likeliness to consider DIY repair. Our results are relevant for practitioners aiming to increase electronic product DIY repair.

## Introduction

The growing amount of electronic product waste (e-waste) is becoming increasingly problematic worldwide (Parajuly et al., 2019). Repair has been addressed as a promising strategy to counter the environmental issues resulting from our current consumption and production patterns (Bocken et al., 2016). However, repairing electronic products when they are malfunctioning or broken is not yet common (Magnier and Mugge, 2022). Consumers encounter many barriers to repair, such as high costs, lack of spare parts, and limited knowledge and ability (Ackermann et al., 2021; Jaeger-Erben et al., 2021; Nazlı, 2021; Rogers et al., 2021; Svensson et al., 2022). Prior research implied that consumers' limited ability to repair may be caused by the way products are designed (Raihanian Mashhadi et al., 2016). For instance, smartphone casings are often glued, which takes more time and effort to disassemble.

Modularity has been addressed as a design strategy to enhance the physical reparability of products (Mestre and Cooper, 2017; Mugge et al., 2005; Schischke et al., 2019). A modular product consists of independent 'building blocks' (modules) and is designed in such a way the modules can be easily replaced or repaired when malfunctioning (Bonvoisin et al., 2016). In addition to enhancing repair, modularity potentially allows consumers to keep their products up to date with new technologies via upgrades, thereby increasing lifetime expectations (Den Hollander, 2018; Ülkü et al., 2012). Therefore, modularity can be beneficial for slowing down resource loops (Bocken et al., 2016). Yet, the fact that products are physically designed to be repaired, does not mean consumers will act accordingly (Makov and Fitzpatrick, 2021).

A study on current users of modular smartphones demonstrated a strengthened perceived ability for DIY ('do-it-yourself') repair (Amend et al., 2022). However, these users may not reflect the average consumer because modular products are not (yet) the norm. Many consumers are accustomed to involving professionals to repair electronic products, such as smartphones and washing machines (Magnier and Mugge, 2022). A modular design would make it easier for consumers to repair products themselves, which is often cheaper and faster, but also demands a change in their current behavior. We contribute to the literature by investigating the impact of a modular design on consumers' likeliness to get the product repaired as well as to conduct DIY repair.

## The likeliness and perceived difficulty to repair modular products

At present, consumers generally do not believe products are designed to be repaired (Van den Berge et al., 2022; Wieser et al., 2015), and their likeliness to consider repairing a malfunctioning product is low (Magnier and Mugge, 2022). This low likelihood to repair is partly due to the associated difficulty of the repair task (Pozo Arcos et al., 2021; Svensson et al., 2022). Research showed that a high perceived difficulty reduces the attractiveness of a task because it may seem unfamiliar to the consumer (Pocheptsova et al., 2010). A modular design is intended to counter this negative perception of repairing consumer electronics. The fact that the modules can be easily disassembled may result in a more attractive repair task because it would be less effortful and time-consuming. Therefore, we expect that modularity will decrease the perceived difficulty of the repair task, which will positively influence consumers' likeliness to repair. Accordingly, we hypothesize:

*H1: Consumers are more likely to repair an electronic product with a modular design than one with a conventional design*

*H2: The perceived difficulty of the repair task mediates the effect of modularity on the likeliness to repair*

## Study 1

### *Method*

The experiment had a 2 (product category: washing machine vs. smartphone) x 2 (product design: conventional vs. modular) between-subject design. Washing machines and smartphones are commonly owned and the environmental impact decreases when their current average lifetime is prolonged (Bakker and Schuit, 2017). Furthermore, the perceived ability to repair these products is low (Jaeger-Erben et al., 2021). We decided to include a 'workhorse' product (i.e., valued for its functional utility) and an 'up-to-date' product (i.e., susceptible to changes in appearance or technology) to consider differences in repair attitudes among product categories (Cox et al., 2013; Pérez-Belis et al., 2017).

We created four scenarios using commonly occurring failures. For the washing machine, the drum bearings were worn out, and for the smartphone, the battery was not working properly (Thysen and Berwald, 2021). We deliberately chose a defect that resulted in a reduced product performance rather than a complete breakdown. The latter may urge immediate action because daily routines are disrupted. Since we aimed to investigate the effect of modularity, we wanted to limit the influence of urge in the repair consideration of the participants. To ensure repair would still be considered a valuable option (Van den Berge et al., 2021), the moment the defect occurred was defined between the mandatory warranty period and average use time (Wieser et al., 2015) (washing machine: 6 years; smartphone: 2 years and 2 months). We used the same brandless product pictures for the conventional and modular scenarios, cf. figure 1. The products were introduced as mid-range models with normal performance. For the modular conditions, the scenario textually explained the product consisted of several independent smaller parts (modules), which can be easily replaced or repaired when malfunctioning.

**Figure 1. Pictorial stimuli of Study 1.**

Participants were recruited online via Prolific. All participants (n=155) were from the UK, above 25 years old (Mage=38.79, SD=11.22, Male=49.7%, Female=48.4%, Other=1.9%), and indicated to own a washing machine/ smartphone. All passed the attention check.

Participants evaluated the scenarios on their general likeliness to repair ('How likely/inclined/willing are you to have this product repaired?'; 1=strongly disagree; 7=strongly agree; $\alpha$=.97 adapted from White et al., 2011) and perceived difficulty of the repair task ('Repairing the product described in the situation above ...is easy/hard; …is easy/hard to complete; …will take little/much time; $\alpha$=.88; adapted from (Pocheptsova et al., 2010) on 7-point scales. We additionally included two single items to measure the likeliness for DIY and professional repair, 'How likely are you to repair this product yourself/have this product repaired by a professional repairer?' (1='not at all'; 7='very much'). Finally, the participants completed a manipulation check on the degree of modularity ('This product is made of modules that are easily replaceable', 'It is easy to replace malfunctioning parts in this product', 'through its design, this product supports the replacement or repair of malfunctioning parts' (1 = strongly disagree; 7 = strongly agree; $\alpha$=.91).

### *Results*

We conducted bootstrapped (5000 samples) parametric tests as these are fairly robust when the assumption of normality is violated (e.g., Blanca et al., 2017). An independent sample t-test with product design as the independent variable and the degree of modularity as the dependent variable showed our manipulation was successful ($M_{conventional}$=3.88 vs. $M_{modular}$=6.36, $t(153)=-12.58, p<.001$).

We performed three two-way ANOVAs with product design and product category as independent variables and the three types of repair likeliness as dependent variables. For the general likeliness to repair participants were significantly more likely to repair the modular than the conventional product ($M_{conventional}$=4.15 vs. $M_{modular}$=5.35; $F(1,151)= 17.86; p<.001$), confirming H1. Furthermore, a marginally significant main effect suggested a higher general likeliness to repair washing machines than smartphones ($M_{washingmachine}$=5.02 vs. $M_{smartphone}$=4.48; $F(1,151)=3.68; p=.06$). No significant interaction effect was found.

Interestingly, the modular design did not significantly increase the likeliness for DIY repair. Instead, participants were more likely to professionally repair a modular product compared to a conventional one ($M_{conventional}$=4.54 vs. $M_{modular}$=5.59; $F(1,151)=11.20; p<.001$). More specifically, the marginally significant interaction effect between the product design and product category on likeliness to professional repair ($F(1,151)=3.05; p=.08$) suggests that a modular design is more influential in enhancing professional repair for smartphones. Even though the general likeliness to repair significantly increased for modular washing machines, the effect of modularity on professional repair likeliness was not significant. Nevertheless, the means are in the expected direction, cf. table 1.

| | **Washing machine** | | **Smartphone** | |
|---|---|---|---|---|
| | Conv. (n=39) | Mod. (n=40) | Conv. (n=40) | Mod. (n=36) |
| Degree of modularity | 3.90 (1.45) | 6.37 (.84) | 3.88 (1.42) | 6.36 (1.12) |
| General likeliness to repair | 4.52 (1.84) | 5.53 (1.59) | 3.78 (2.03) | 5.18 (1.51) |
| Difficulty of the task | 4.76 (.96) | 3.63 (1.39) | 4.00 (1.56) | 2.90 (1.54) |
| DIY repair likeliness | 1.95 (1.75) | 2.28 (1.84) | 2.40 (2.16) | 2.81 (2.23) |
| Professional repair likeliness | 4.97 (2.08) | 5.48 (1.88) | 4.10 (2.19) | 5.69 (1.53) |

**Table 1. Descriptive statistics of the four conditions of Study 1.**

Finally, we performed a mediation analysis to check whether the perceived difficulty of the task explains the effect of the modular design on the likeliness to repair. Using PROCESS model 4 (Hayes, 2013), the indirect effect showed significant results (b=.28; BootSE=.11; 95%CI:[.08,.05]). Specifically, modularity negatively influenced the perceived difficulty of the task (b=-1.09; SE=.23; 95%CI:[-1.54;-.64] p<.001), which in turn had a positive effect on the likeliness to repair (b=-.26; SE=.10; 95%CI:[-.45;-.06]; p<.05). Our results thus indicate a partial mediation, confirming H2.

### *Discussion*

The findings of study 1 showed that modularity increased the general likeliness to repair, which was explained by a decreased perceived difficulty of the repair task. However, a modular design only influenced the likeliness to consider professional repair. This is surprising as we often implicitly assume that modular designs would encourage DIY repair, as the replaceable modules would make repair easier to conduct and could also save expensive labor costs. Therefore, exploring what would increase the likeliness to DIY repair modular smartphones is interesting to explore further.

## Design cues and the likeliness to DIY repair modular products

Even though modular products encourage repair, consumers do not feel sufficiently able to do such repairs themselves. Instead of consulting a professional repairer, designers may further support them to increase their perceived ability to conduct DIY repair. Research suggested that design interventions (i.e., affordances) can be useful to prompt consumers to adopt sustainable behavior (Bhamra et al., 2011; Ohnmacht et al., 2018). Affordances are defined as "action possibilities in the environment in relation to the action capabilities of the user" (Gibson, 1977). It prompts a specific use or interaction with the user, for example, a handle on a door invites you to open it.

Repair affordances thus represent the repair action possibilities in the relation between the user and a malfunctioning object. For example, for repair consumers generally need to open the product, diagnose the problem, relate this to the correct component, and replace this component with a new one. All are repair affordances, and if modular products do not sufficiently support consumers in these actions, DIY repair is unlikely to happen. To increase the ability for DIY repair, signifiers, which are physically perceivable cues, are needed to support the specific repair steps and can make them more easily processed (Norman, 2008).

Different types of cues can be designed to bring about repair affordances. For example, a cue on the outside that indicates where to open the product could make it easier to start the repair task, or a cue inside the product could make the to-be-repaired component easier to identify. Therefore, we hypothesized the following:

*H3: Consumers are more likely to DIY repair a modular product when the design includes explicit repair cues*

## Study 2

### Method

The experiment used a 2 (outside cue: present vs. absent) x 2 (inside cue: present vs. absent) between-subject design. We focused on smartphones because these are often replaced even with minor defects, and DIY repairs can cut repair costs. Additionally, some examples of modular/ repairable smartphones are available on the market (e.g., Fairphone, Nokia) making our insights relevant to practitioners.

In line with study 1, the smartphone was introduced as a mid-range model with normal performance. The time of ownership was 2 years and 2 months, and brand names were removed, cf. figure 2. In all scenarios, the smartphone had a modular design with a failing battery. We included two types of cues. One was a notch (i.e., inlet) on the smartphone's exterior, which can be used to open the device. One was an icon on the inside indicating the smartphone's components (e.g., battery), which was shown on the website/(online) manual. Participants were recruited similarly to Study 1. All owned a smartphone (n=158, Mage=41.37, SD=13.56, Male = 50%, Female = 50%, Other = 0%), and passed an attention check.

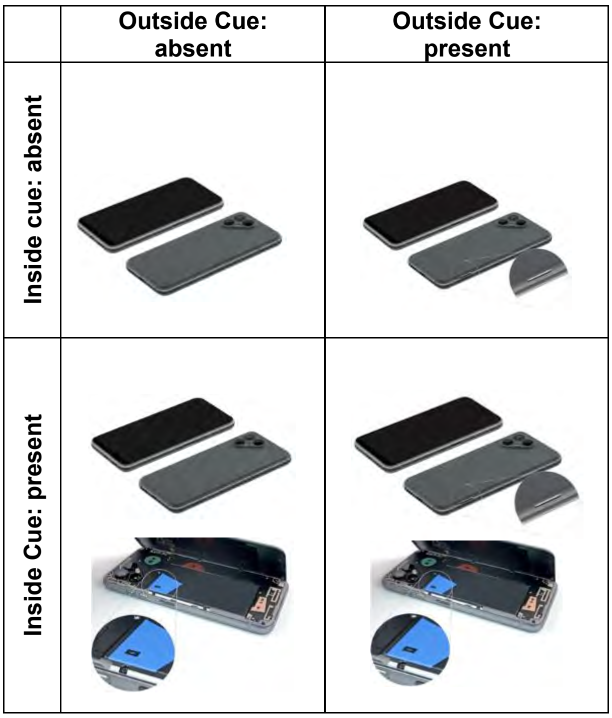

**Figure 2. Pictorial stimuli of Study 2.**

Similar to study 1, we measured the general likeliness to repair (α=.94) and the perceived difficulty of the repair task (α=.90). We measured the likeliness for DIY and professional repair on 3-item scales ('How likely/inclined/willing are you to repair this product yourself' α=.97/to have this product repaired by a professional repairer?'; 1='not at all'; 7='very much' α=.96). We checked our manipulations on 3-item scales (1=strongly disagree; 7=strongly agree) for the outside cue ('It is immediately evident/clearly indicated where this smartphone can be opened', 'I do not expect to have difficulties to open this smartphone'; α=.88) and the inside cue ('It is immediately evident/clear how different components could be identified inside this smartphone', 'I do not expect to have difficulties to identify different components'; α=.92).

### *Results*

We performed two bootstrapped independent t-tests with the cues as the independent variables and the accompanying manipulation check as the dependent variable. The results showed that both manipulations were successful ($M_{no\_OutCue}$=4.31 vs. $M_{OutCue}$=6.21, t(156)=-9.17, p<.001; $M_{No\_InCue}$ =4.06 vs. $M_{InCue}$=5.50, t(156)=-6.34, p<.001).

| | Outside cue: absent | | Outside cue: present | |
|---|---|---|---|---|
| | **Inside cue: absent** (n=40) | **Inside cue: present** (n=41) | **Inside cue: absent** (n=37) | **Inside cue: present** (n=40) |
| Manipulation outside cue | 3.61 (1.54) | 4.99 (1.34) | 6.20 (.85) | 6.22 (.95) |
| Manipulation inside cue | 3.72 (1.63) | 5.64 (1.04) | 4.42 (1.64) | 5.35 (1.46) |
| General likeliness to repair | 5.29 (1.70) | 5.90 (1.20) | 5.50 (1.58) | 6.08 (1.29) |
| Difficulty of the task | 2.59 (1.26) | 2.46 (1.31) | 2.38 (1.09) | 2.38 (1.30) |
| Likeliness DIY repair | 4.06 (2.23) | 4.84 (2.18) | 4.32 (2.28) | 5.42 (1.91) |
| Likeliness Prof. Repair | 4.05 (1.83) | 3.85 (1.99) | 4.35 (2.03) | 3.57 (1.86) |

**Table 2. Descriptive statistics of the four conditions of Study 2.**

We performed three two-way ANOVAs with the cues as independent variables and the three types of repair likeliness as dependent variables. In general, participants were more likely to repair the modular smartphone in the presence of an inside cue compared to when such a cue was absent ($M_{No\_InCue}$=5.40 vs. $M_{InCue}$ =5.99; F(1,154)=6.61; p<.05), which was not the case for the outside cue. The interaction was also insignificant. The ANOVA with the likeliness for DIY repair as a dependent variable showed similar results and participants were thus more likely to perform DIY repair when an inside cue was provided ($M_{No\_InCue}$ =4.19 vs. $M_{InCue}$=5.13; F(1,154)=7.46; p<.01), which was not the case for the outside cue. The interaction was insignificant as well. The likeliness for professional repair did not significantly change by both cues, cf. table 2.

## Discussion and implications

Our research confirms the potential of modular design to stimulate repair (Mugge et al., 2005; Schischke et al., 2019), and that technically repairable products do not automatically lead to repair behavior (Makov and Fitzpatrick, 2021). Our empirical findings showed that consumers need support in their repair ability. We demonstrated that a repair cue that facilitates the consumer during the repair task would be most effective to encourage DIY repair.

Although our study provides interesting insights into how to successfully implement modularity, our results do not explain why the inside cue was more effective than the outside cue. Reflecting on our stimuli, participants could have experienced more support via the icon, as it facilitated the repair act itself, compared to facilitating where to start the repair via the notch. Therefore, for a modular product, the opening may not be considered a big constraint, and the focus should be on cues that support during the repair act. Finally, we must note that the visual information (i.e., a picture of the inside of the smartphone) of the inside cue scenarios could have additionally supported consumers. Processing fluency theory addresses the importance of (visual) declarative information to ease the task (Schwarz et al., 2021), and this thus may have helped to envision the repair steps and to reassure them that performing a repair is within their capabilities. To stimulate DIY repair of modular products, we, therefore, recommend including clear declarative information in addition to explicit repair cues in the design.

# Spinning out of control – reflections on the (non)sense of repurposing as a circular economy loop

**Jasper van Kuijk[a], Renee Wever[b]**
a) Delft University of Technology, Delft, The Netherlands
b) Linköping university, Linköping, Sweden

**Keywords**: Repurposing; Recycling; Inner loops; End-of-life; Design strategy.

**Abstract**: Within design for circular economy, the power of the inner loops is frequently stressed. The closer one can stay to the original product, retaining its shape and value, the better it is thought to be from a circular economy perspective. One of those loops, inside of material recycling, is repurposing: re-applying parts and materials with a pre-use history in new and different applications. Showing the history or previous life of the material is then deemed a value-adding aspect.

Repurposing, or upcycling, has worked well in artistic one-off solutions, but presents challenges when scaled to higher volumes, due to fluctuations in material flows and the challenges associated with processing larger volumes of waste streams. However, scaling up of repurposing is required if a meaningful environmental contribution is to be achieved.

By contrasting four cases, analyzing previous design projects, on 1) railway timetables into consumer products, 2) on turbine blades into playgrounds, 3) truck tarps into bags and 4) on dining room chairs into wooden games, we explore when and how repurposing makes sense and when it doesn't.

We explore how well expected material stream volumes match proposed applications. We contrast what would be the alternative, outer-loop process for each material stream, and how future looping is affected by the repurpose loop. We re-assess the 'inner loop'-principle using the concepts of flexibility of application and batch entropy. We argue that in terms of circularity and sustainability, in cases where the waste material can be recycled well, such a route through the outer loop back to inner loops, may be preferable to opting for the tighter 'repurpose loop' if that represents a high change of spinning out of your control and ending-up in incineration.

## Introduction

In the frequently referenced butterfly model of the circular economy from the Ellen MacArthur Foundation (e.g. Ellen MacArthur Foundation, 2013, p24), there is no dedicated loop for re-purposing, the recovery of existing products or parts thereof and then re-applying these in a new context and with a new function (Den Hollander et al, 2017; Eike et al, 2020). If it were included in the butterfly model a re-purpose loop would most likely lie between the refurbish/remanufacture loop and the outer loop of material recycling (see Figure 1).

A basic adage of design for a circular economy, is the power of the inner loops (Ellen MacArthur Foundation, 2013, p.30). In general, the closer one can stay to the original product, retaining its shape and value, the better it is thought to be

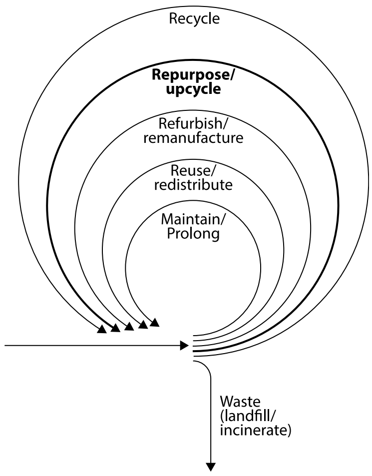

**Figure 1. The repurpose loop added to the butterly model of the circular economy by the Ellen MacArthur Foundation.**

from a circular economy perspective. Considering this, re-purposing could be considered preferrable to material recycling. This paper aims to reflect under which conditions that is actually true, by reflecting on future potential beyond the initial loop of either re-purposing or recycling.

So far, repurposing, sometimes also referred to as upcycling, has been mainly applied in artistic one-off solutions, where it has worked well. It presents challenges however, when scaled to higher volumes, due to fluctuations in material flows and the challenges associated with processing larger volumes of waste streams. Scaling up of repurposing would be required though, if a meaningful environmental contribution is to be achieved. But then we are automatically talking about diverting relatively large, relatively homogeneous materials streams.

## Aim

We therefore explore how well expected material stream volumes match proposed applications. We contrast what would be the alternative, outer-loop process for each material stream, and how future looping is affected by the repurpose loop. We thus re-assess the 'inner loop'-principle using the concepts of flexibility of application and batch entropy and explore when repurposing makes sense and when not.

## Methodology

We first discuss the three concepts that we identified as being important for re-evaluating the inner loop principle, namely: re-application bandwidth, waste stream entropy and waste stream volume. We then assess those concepts on four real-world design projects, which serve as scenarios against which the concepts can be matched, and which allow us to explore when and how repurposing makes sense and when it does not or does to a lesser extent. The four projects are: 1) railway timetables into consumer products, 2) turbine blades into playgrounds and street furniture, 3) tarpaulins into bags and 4) dining room chairs into wooden outdoor games.

## Central concepts

Below we discuss three concepts that we identified as central for assessing to which extent it is desirable to repurposing a waste stream.

### *Re-application bandwidth*

The first challenge in large-scale repurposing is the (in)flexibility of application of the waste/material stream that is to be reprocessed. Repurposing makes sense from a value-keeping perspective, but it does require quite some design effort to fit an existing element, component or product in a new context (see Figure 2) in a way that sufficient value is offered.

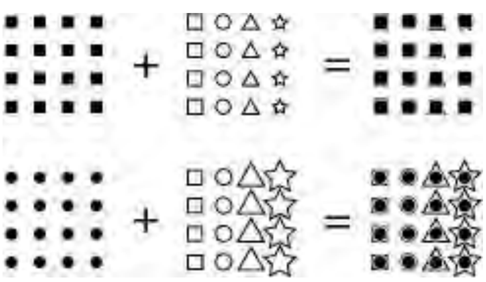

**Figure 2. Without altering it, a material/waste stream may not fit many new contexts of use (upper row). Depending on the type of material/waste, and on how many new contexts of use are identified, more matches for contexts where products/elements can be successfully repurposed may be identified (lower row).**

To create a successful market for a reclaimed material, one needs to not look at the value that is captured in the current item, but also at in what form the reprocessed item (complete product, construction element or base material) can offer most value on the market. By already taking repurposing into account during the design process of the initial product or component, reapplication bandwidth can be increased, and required efforts and resources for reapplication can be reduced (Schild, 2020).

### *Waste stream entropy*

Entropy is a core concept of thermodynamics, and refers to a measure or disorder, randomness or uncertainty of a system, or in this case, of a waste stream (See Figure 3). Waste stream entropy influences how big and homogenous the batches are of similar products, modules or materials. And thus also the (financial) viability of reprocessing a waste stream, as standardized, high-volume processes are much more efficient than custom, small-scale processes.

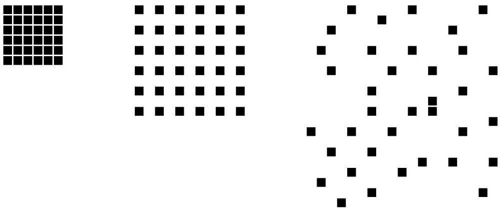

**Figure 3. With repurposing, often the waste stream is divided into small unis, and the entropy (distribution, randomness) increases.**

The second law of thermodynamics states that: “entropy of isolated systems left to spontaneous evolution cannot decrease with time as they always arrive at a thermodynamic equilibrium.” This implies that once separated, materials and products will not spontaneously reform as a homogenous batch of considerable size. However, just as in thermodynamics, the entropy of a waste stream can be reduced by adding energy (effort). Then the size, density and homogeneity of a waste stream can be increased again (see Figure 4). For example, users can be stimulated to separate waste streams to increase their homogeneity. Or a deposit system can stimulate users to bring back bottles to the supermarket. Another example is a materials passport (Rau, 2022) or distribution logbook, which can help to identify where products or materials are, and what their composition is, thus stimulating recollection.

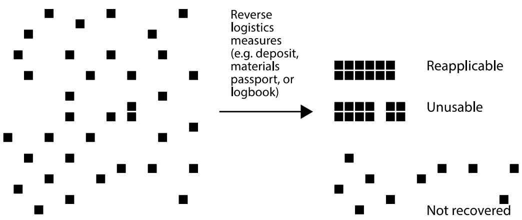

**Figure 4. Recollection measures can stimulate entropy (distribution, disorder, randomness) of a waste stream to be decreased again.**

*Waste stream volume*

This concept covers how much of the product, module or material is produced over time and needs to be reprocessed (see Figure 5). Because of the sheer volume of waste, and because the existing shape and structure may limit the possibilities for application, in some cases, it may be preferable to move the waste stream to the more ‘outer loop’ of material recycling, as the flexibility or application bandwidth for raw materials is much higher than for components or complete products.

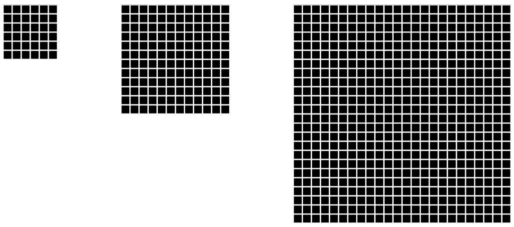

**Figure 5. Waste stream volume influences how many components or products need to be reprocessed, and thus how big of a ‘receiving context’ for the repurposed stream needs to be found, or, alternatively how big the reapplication bandwidth of the reprocessed waste stream should be.**

## Benchmark projects

For each project a qualitative assessment is provided of the waste streams reapplication bandwidth, entropy and volume, and how the chosen loop of the butterfly model (for example, recycling or repurposing) altered this.

*Project 1: Railway time-tables*

**Figure 6. railway time table re-purposed into a service tray.**

Old plastic railway timetable signs made from polystyrene were ‘upcycled’ in the form of, among others, book covers and serving trays (see Figure 6). Here the upcycled product gained a higher value than the waste, and possibly even than the original timetables, as consumers highly appreciated the well-known aesthetic of the timetables which was featured on the products.

The reapplication bandwidth of the batch of discarded timetables was considerable, as it is viable to recycle polystyrene and use it for injection molding of new products. However, as a product, the reapplication bandwidth of the timetables is fairly low, as it is harder to find contexts in which time tables can offer the same value. In this case, the value was mostly found in the styling, creating products that still showed the features of the old timetables. This strategy caused batch of considerable size of recyclable material to be cut up into many items, sold to individual, untracked customers. At end-of-life the repurposed products are likely to be incinerated or end as landfill. This is less problematic as the original waste stream size is not so big and there is not a continuous output. However, in terms of circularity in the longer run, in this case material recycling (outer loop) would have been preferable over upcycling of the original timetable (more inner loop).

| | *Initial waste stream* | *Repurposed stream* |
|---|---|---|
| Reapplication bandwidth | ●●●●○ | ○○○○○ |
| Entropy | ●○○○○ | ●●●●● |
| Volume | ●○○○○ | ●○○○○ |

**Table 1. Indicative comparison of the properties of the initial waste stream and the repurposed stream of the railway timetables.**

### *Project 2: Turbine blades into playgrounds and street furniture*

**Figure 7. One of the playgrounds made out of discarded turbine blades (Photo taken from Medici et al 2020).**

In a pilot project wind discarded turbine blades were transformed into children's playgrounds and street furniture (Jensen 2018, Mishnaevsky 2021). Because turbine blades are made of composites of epoxy resins and glass fibers, they are very hard to recycle. However, due to the increasing application of wind energy there is a large and increasing volume of discarded wind turbine blades. Therefore, the idea was to prolong the lifespan of the blades by creating children's playgrounds and street furniture out of them (see Figure 7). Thus, even though the initial waste stream has a limited reapplication potential, because of the highly specific form factor of the turbine blades, through a creative step, a new application was found. It was stated that if 5% of the Netherlands' yearly production of urban furniture was using wind turbine blades, the whole Dutch annual turbine blade waste stream would be absorbed (Jensen 2018).

Although repurposing prolonged the life span of most of the components/material, the repurposed stream subsequently had a limited reapplication bandwidth, which was reduced further by wear and tear (Medici et al, 2020). Also, the entropy of the repurposed stream would increase, as the material would end up in playgrounds in various locations, and there was no system in place to take care of the ultimate end-of-life of the repurposed turbine blades.

In addition, it can be doubted whether the proposed 5% annual market share of new street furniture is feasible considering the highly specific form factor and material properties of the repurposed designs. Although the proposed repurposing could mean a temporary storage of the waste stream and prevent the use of (virgin) materials, absorption of the complete waste stream of turbine blades seems improbable.

Because of the low reapplication bandwidth and the high waste stream volume, in this case it seems that the most preferable option would be to improve recycling processes at the material level for the current turbine blades (outer loop), as well as the development of a new generation of blades, with materials and a design aimed at recycling.

| | *Initial waste stream* | *Repurposed stream* |
|---|---|---|
| Reapplication bandwidth | ●○○○○ | ○○○○○ |
| Entropy | ●○○○○ | ●●●○○ |
| Volume | ●●●●○ | ●○○○○ |

**Table 2. Indicative comparison of the properties of the initial waste stream and the repurposed stream of the wind turbine blades.**

## *Project 3: Truck tarps into bags*

**Figure 8. Bag made out of tarpaulin by Freitag.**

Freitag makes bags from tarpaulins (see Figure 8), and in 2017 the company reported an annual output of 300,000 products and the recycling of 300 tons of tarpaulin per year (Sung et Al, 2022). As with the train tables, the entropy of the waste stream increases highly when it is repurposed, as smaller pieces of tarp will each go with their individual customer. However, in this case that is less problematic, as the reapplication bandwidth of the original material was very low, with landfill/incineration as the likely path. Furthermore, the waste stream is of a large volume, even to the extent that the Freitag products cannot complete absorb the stream. This raises the question of whether in addition to repurposing, a recycling path is needed.

| | *Inititial waste stream* | *Repurposed stream* |
|---|---|---|
| Reapplication bandwidth | ●○○○○ | ○○○○○ |
| Entropy | ●○○○○ | ●●●●● |
| Stream volume | ●●●●○ | ●○○○○ |

**Table 3. Indicative comparison of the properties of the initial waste stream and the repurposed stream of the tarpaulin bags.**

## *Project 4: Dining room chairs into games*

**Figure 9. Kubb game made out of re-purposed dineing room chairs. (Berglund, 2022)**

This case was studied as a master thesis project (Berglund, 2022) and is reported more elaborately elsewhere (Berglund et al, 2023). It deals with a Swedish second-hand mall, where donated products come in and are sold (as-is or repaired, re-upholstered, remanufactured, or repurposed) by the entrepreneurs in the mall. This system is operational, but the inflow of dining room chairs is much bigger than can be sold as chairs again. Hence, currently a considerable number of chairs is diverted to waste treatment and energy recovery every week. As one solution direction, re-purposing the wooden chairs into typical Swedish outdoor games was explored (Figure 5).

The current alternative for the chairs is energy-recovery. The repurposed games would, once discarded, likely enter a similar waste treatment.

Batch-size potential of selling games may be limited, but there is aesthetic potential to truly use the pre-use history of the materials (see e.g. Lepelaar et al, 2022) as a value-enhancing feature.

| | *Original waste stream* | *Repurposed stream* |
|---|---|---|
| Reapplication bandwidth | ●●○○○ | ●○○○○ |
| Entropy | ●○○○○ | ●●●●● |
| stream volume | ●●○○○ | ●○○○○ |

**Table 4. Indicative omparison of the properties of the initial and repurposed stream of the kubb games made out of chairs.**

## Discussion and conclusions

Repurposing, as a circular strategy is under-researched in the literature, certainly at larger scales than one-offs. In the common circular economy model, the logical place for a re-purpose loop would be between remanufacturing/reupholstering and recycling. That would also imply that repurposing is less desirable than remanufacturing, but more desirable than material recycling. In this paper, we have critically examined that position. To properly assess the circular and sustainability performance, one needs to look on the one hand at what level of virgin material application has been prevented, but on the other hand also at what future material recycling loops may have been lost or made much more difficult.

A danger of repurposing is that by going to the inner loop, there will be no more subsequent loops. We argue that in terms of circularity and sustainability, in cases where the waste material can be recycled (both technically and economically), that might be preferable to staying in the more inner 'repurpose loop' as there the material might spin out of your control and end-up in incineration at their next end-of-life phase.

We have provided three basic aspects by which designers can analyze both their proposed repurposing scheme, and the paths thus not chosen:

- Re-application bandwidth, for the technical and economic value of the waste stream as a material, component or product,
- Waste stream entropy, for the technical and economic potential of future circular loops after re-purposing,
- Waste stream volume, for assessing how the potential volume of a repurposed stream relates to the volume of the generated waste stream.

Reapplication bandwidth, entropy and waste stream volume seem useful indicators to assess whether upcycling is sensible.

With one-offs or limited volumes, it might be possible to find an acceptable or suitable repurpose-context, but if the volume of to-be-repurposed items goes up, it becomes harder to find niches for which the repurpose item is suitable.
Repurposing does seem to make sense if the reapplication bandwidth is limited and volume is low.

# Feasibility of On-demand Additive Manufacturing of Spare Parts

**Alma van Oudheusden[a], Arjan Buijserd[a], Zjenja Doubrovski[a], Bas Flipsen[a], Jeremy Faludi[a], Ruud Balkenende[a]**
a) Delft University of Technology, Delft, The Netherlands

**Keywords**: Additive manufacturing; 3D printing; Repair; Spare parts; Sustainable design.

**Abstract**: Spare parts availability is crucial for extending the life of consumer products. However, long-term availability could lead to high stocks of spare parts, which might not be used. Instead, on-demand manufacturing of spare parts with additive manufacturing (AM) is a promising alternative. This paper presents a method to evaluate parts on their eligibility for AM spare parts. The parts evaluation is based on AM technology accessibility as well as part requirements. This method was tested by assessing all parts of the Dyson V11 broom-stick vacuum-cleaner and validated by printing and testing a selection of parts. For this, both plastic and metal spare parts were made through fused deposition modelling (FDM), stereolithography (SLA), binder jetting (BJ), material jetting (MJ), selective laser melting (SLM), selective laser sintering (SLS), and multi jet fusion (MJF), using both desktop FDM printers and off-site service providers. Based on these results, we conclude that currently only a small number of parts can be replaced by additive manufactured parts without considerable redesign efforts. AM parts can compete on price with the current stocked parts, but may be more expensive for other products. We also identified additional functional requirements for evaluating the eligibility of a spare part for AM.

## Introduction

The 2014 EU circular economy strategy considers maintenance and repair important ways of preserving resources and prolonging consumer products' lifespan (Šajn, 2019). To conduct repairs, access to spare parts, tools, and information is required, which are often controlled by the original equipment manufacturer (OEM) of the product (Svensson-Hoglund et al., 2021). The spare parts inventory is normally held by an OEM or third-party service provider to fulfil warranties (Zhang, Huang, & Yuan, 2021). This means that consumers can only repair their products for a short time (typically 2 years) and only through the OEM service (Hernandez & Miranda, 2020). Spare parts may not be available when the production of the products ceases (Zhang, Huang, & Yuan, 2021). Instead, it can become more cost effective for OEMs to replace a broken product, which further affects spare part availability (Frenk et al., 2019; Van Der Heijden & Iskandar, 2013).

The 2019 EU Ecodesign regulations include reparability requirements, like increased spare part availability. Manufacturers need to ensure that specific parts are available within 15 working days for seven to ten years after the last market release (European Commission, 2019; Šajn, 2022). The European Commission is exploring the potential of implementing a repair score system based on repair, reuse, and upgrade standard EN 45554 (European Commission, 2022, p. 7).

Long-term spare part availability means that OEMs need to find cost-effective ways to keep spare parts stock for older models (Svensson-Hoglund et al., 2021). To increase spare part availability while preventing obsolete stocks, on-demand spare parts manufacturing with additive manufacturing (AM) could be used. Digital spare parts can reduce wait time, labour cost, delivery time and costs, emissions, material waste, and inventory (Attaran, 2017; Chekurov et al., 2018). Additionally, AM economics make it ideal for on-demand spare parts manufacturing (Ford, Despeisse, & Viljakainen, 2015).

However, not all spare parts can be 3D printed. Recent research has established printability requirements, especially related to part geometry (Chaudhuri et al., 2020). Van Oudheusden et al. (2023) have shown that AM is less suited to facilitate self-repair due to the redesign that is often needed to make parts manufacturable with AM at a similar mechanical performance. However, AM might be suitable in professional repair. More insight is then needed on to what extent spare parts for consumer products can be replaced by spare parts made with additive manufacturing techniques. We need to be able to evaluate the printability of product parts, based on accessibility, part functionality, and economic feasibility. Thus, the research question of this paper is, "How can we evaluate the printability of product parts based on part requirements?"

To answer these questions, we studied the accessibility of AM methods by looking at which methods are widely available, affordable, and of high enough quality, while considering both direct ownership and printing services. Then, we constructed a list of part requirements and used these in a theoretical assessment of all the parts in a household appliance. This theoretical assessment was then validated through printing and testing a selection of parts.

## Method

Part printability was evaluated for a high-end vacuum cleaner Dyson V11 Torque Drive (about € 650-€700). The Dyson V11 was selected as it is an advanced household appliance offering a multitude of complex parts made from different materials. As such, it is considered an interesting case study.

The vacuum cleaner was fully disassembled using commonly available tools: PH1 (Philips) screwdriver, T8 (Torx) screwdriver, plastic prying tools, needle nose pliers, cutting pliers, flat screwdrivers, and hammer. The hammer and flat screwdrivers were used together to remove smaller parts which could only be removed with considerable force (e.g., the smaller roller wheel axles in the brush head).

The parts were mapped using the Product Breakdown Structure (PBS) method (NASA, 2016). The PBS was complemented with the part material, if identified. For further distinction, parts were only considered "eligible" for additive manufacturing if they were not standardized or commonly available parts, such as fasteners, springs, or bearings. These could likely be purchased faster, more affordably, and at higher quality than they could be printed. Parts that could not be fully disassembled were also not considered eligible. The resulting eligible selection of spare parts would need to be printable through AM.

For assessing part printability, printing methods were considered that are commonly available through service providers: fused deposition modelling (FDM), stereolithography (SLA), binder jetting (BJ), material jetting (MJ), selective laser melting (SLM), selective laser sintering (SLS), and multi jet fusion (MJF).
Printability of parts was assessed on the following eight limiting criteria, as defined by van Oudheusden et al. (2023): (1) exposure to high forces, (2) exposure to high temperatures, (3) accurate fit required, (4) fine details, (5) smooth surface or low friction required, (6) complex curvatures, (7) complex geometries, and (8) complex or inaccessible cavities. Guidelines were defined for each criterion to increase the scoring reproducibility, see Buijserd (2022). Criteria were only marked as applicable if they were essential for part functioning. For example, if a part had complex cavities required for injection moulding but without further functional purpose, the criterion did not apply. A part printability rating was calculated for each part by starting with a score of nine and subtracting one point for each applicable limiting criterion. A part failing all eight limiting criteria scores a 1. A low printability score means a part will be more difficult to print and that careful consideration is needed of the printing method, printing material, and printer settings.

Printed part affordability was evaluated by making three roughly modelled "mock-up" parts. The outer part dimensions and material volumes roughly matched the original parts, but no details were modelled. These mock-ups were submitted to service providers for a price quote, which was then compared to the original spare part cost.

## Results

### *Parts mapping*

The Dyson V11 was disassembled into 174 parts, of which 139 are unique, see Figure 1. The parts are grouped in 23 sub-assemblies, which in turn constitute six main part assemblies. Some subassemblies, like the rear dustbin seal, the motors, and the battery pack, could not be disassembled without breaking the parts or endangering the repairer. Excluding all non-eligible parts gave 67 eligible unique parts.

**Figure 1. The disassembled Dyson V11.**

Figure 2 shows the high-level hierarchical breakdown and the distribution of unique eligible parts over the (sub)assemblies. The brush head has the most with 26 unique eligible parts, followed by the vacuum section with 21 such parts

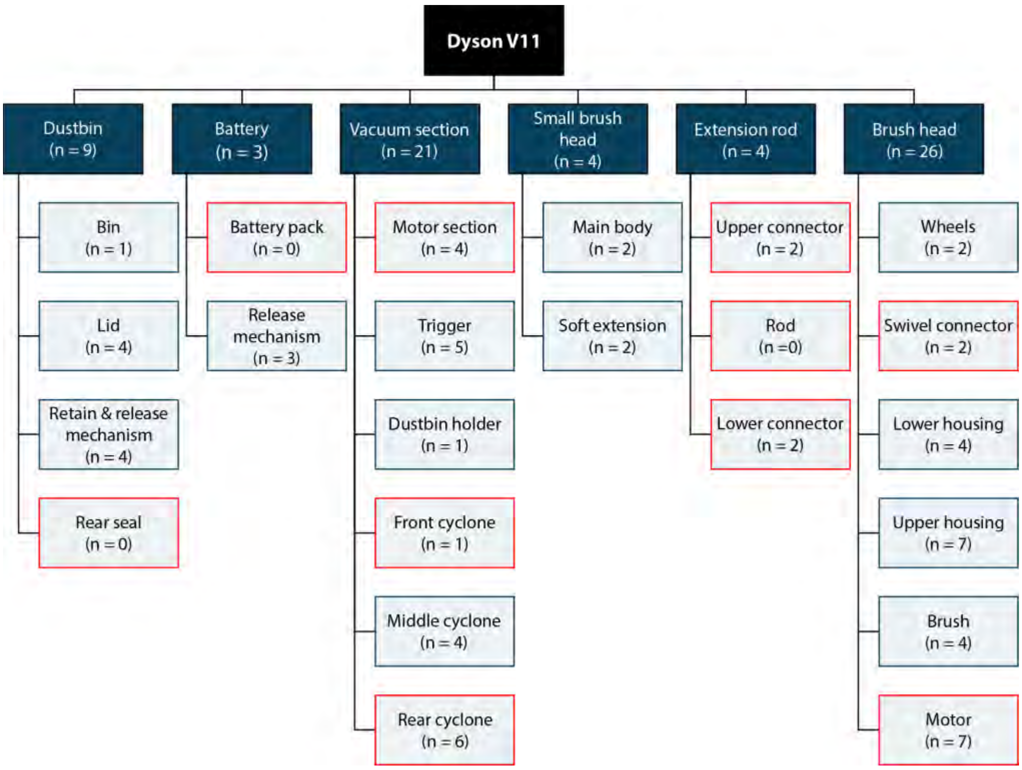

**Figure 2. The Dyson V11 hierarchical breakdown. Darker boxes are assemblies, lighter boxes are subassemblies. The numbers indicate the number of eligible unique parts in each (sub)assembly. A red bevel indicates the subassembly could not be fully disassembled.**

*Materials*

Figure 3 shows most parts are made of plastic, and that many different materials have been used. In total 25 different materials and material blends were identified, but for some materials the exact composition could not be defined. The multi-material group has the largest variety of materials, including nine different combinations.

*Printability*

Each part of the Dyson V11 was assessed using the eight limiting criteria mentioned in the Methods section, see for example Figure 4. Figure 5 shows the part printability scores for all eligible unique parts. Nearly all parts encounter one or more limiting criteria. Most parts encounter one limiting criterion, the lowest score was a three, and only six parts scored 9 out of 9. When assessing these high scoring parts, four of them were found to be flat foam gaskets to close part connections. These were difficult for FDM printing to match material compressibility. The other two parts could be replaced with FDM printed copies.

Still, most parts score relatively well on these criteria, and parts are usually still printable even when multiple limiting criteria apply. For example, the spring clip shown in Figure 4 had three limiting criteria but was printed successfully using SLS, SLM, and BJ.

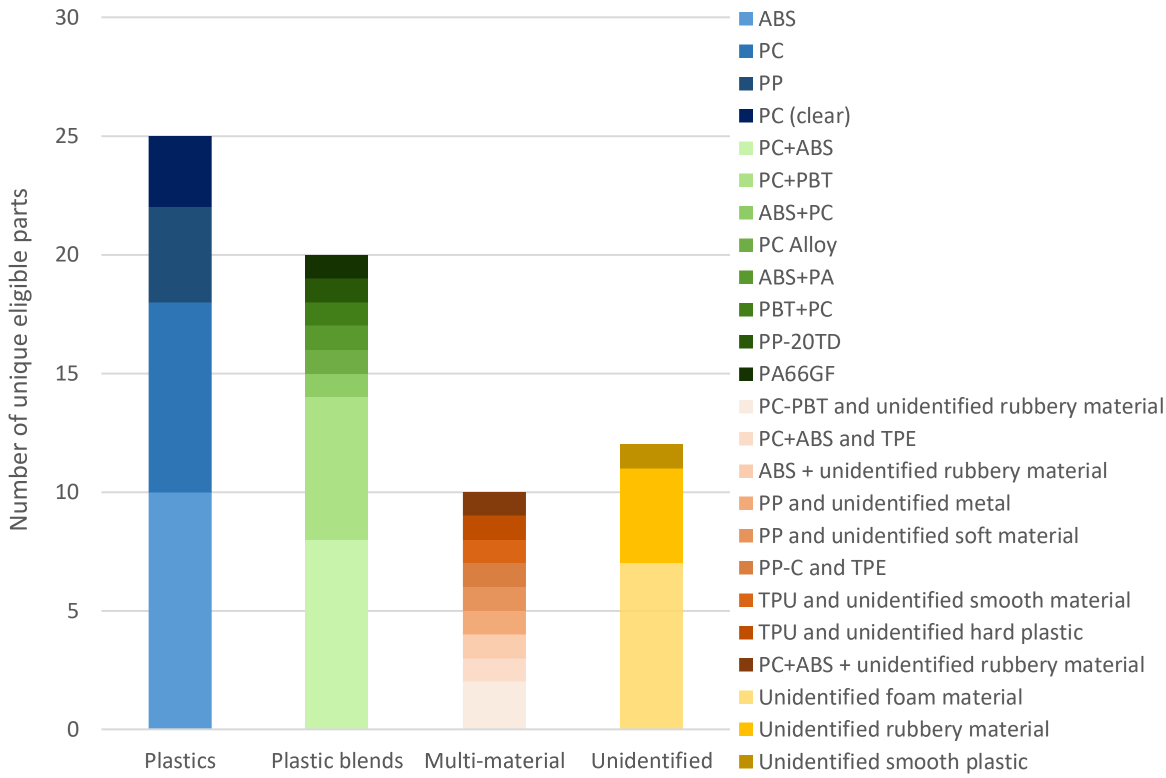

**Figure 3. The material use in the Dyson V11. These materials include (blends of) acrylonitrile butadiene styrene (ABS), polycarbonate (PC), polypropylene (PP), polybutylene terephthalate (PBT), polyamide (PA), thermoplastic elastomer (TPE), PP copolymer (PP-C), thermoplastic polyurethanes (TPU), PP reinforced with 20% talc (PP-20TD), and PA 66 with glass fibre (PA66GF).**

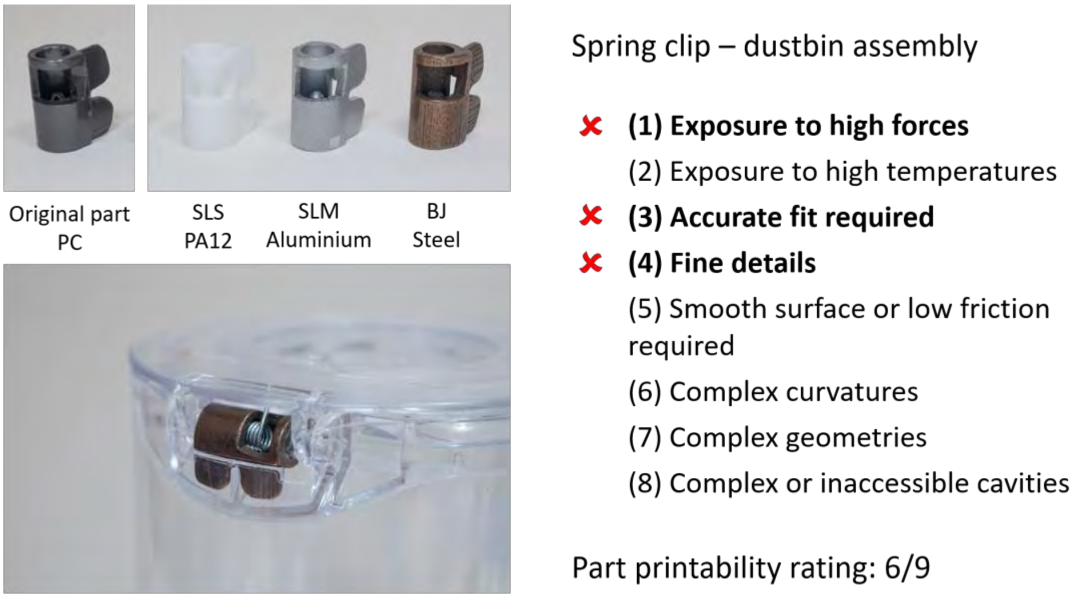

**Figure 4. The spring clip printed in various materials. Limiting criteria that apply are marked with red X'es.**

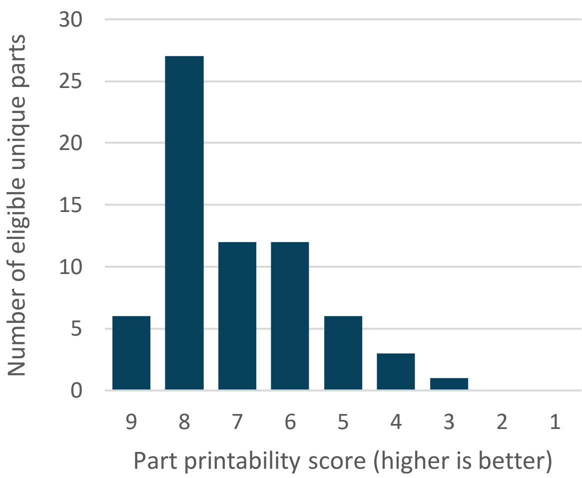

**Figure 5. The Dyson V11 part printability scores.**

Figure 6 indicates the occurrence of each limiting criterion. The main challenge is parts with fine details, which was marked applicable to 29 unique parts, but also other geometry related factors score high. The most frequent functional limiting factor was exposure to large forces during use.

When applying the limiting criteria, we further noticed that multiple parts of the Dyson V11 were made of flexible materials, such as rubber-like seals or soft-touch TPU parts. These materials can have properties like elasticity or flexibility beyond standard additive manufacturing capabilities. Additionally, there were multiple parts made of foam. This is not a common material in additive manufacturing, which can make it difficult to achieve the same compressibility. Other parts were multi-material parts, meaning that the materials of the part are irreversibly connected, such as a metal filter embedded in an injection moulded part. If the part cannot be replaced with a part printed in a single material, other strategies or specific printing methods are required, which are expected to complicate part production.

*Affordability*

The cost of spare parts for the Dyson V11 was assessed and compared with the costs of the printed replacement parts. Dyson offers a replacement for all Dyson V11 parts, but except for the HEPA filter, parts are not sold separately. Instead, consumers are required to buy and replace an entire (sub)assembly. For example, the lid can only be purchased as part of the dustbin reservoir (Dyson, 2023). Prices for original spare parts in this study therefore represent the cheapest option available for the part.

The cost of the printed replacement parts was evaluated by making three mock-up parts for the Dyson V11 and retrieving a price quote from a service provider. Figure 6 shows examples of one part. Table 1 compares the costs for printing three parts (lid, metal filter holder, and retainer clip) against the cost for the OEM replacement.

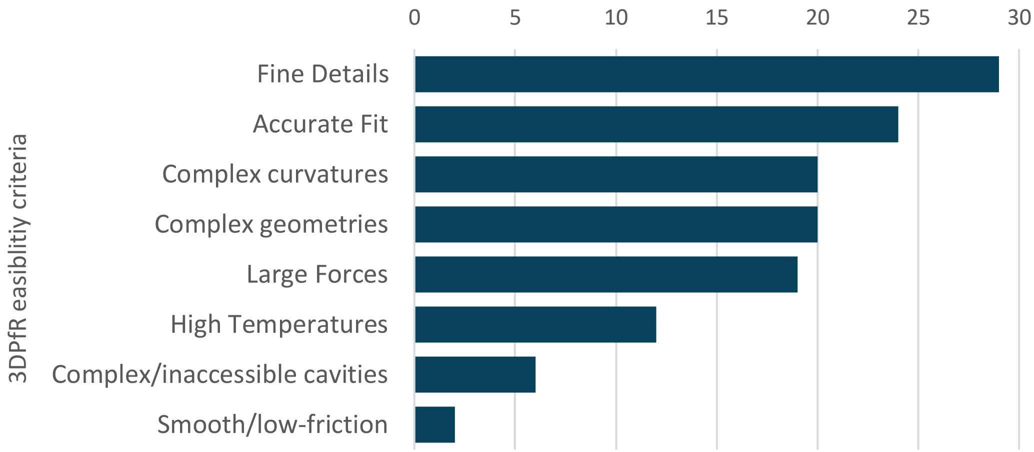

**Figure 6. The occurrence of limiting criteria in the Dyson V11.**

| Part | Cost OEM replacement | SLS | MJF | BJT – steel | SLA – grey | FDM – ABS |
|---|---|---|---|---|---|---|
| **Lid** | € 33.90 | € 19.07 | € 21.04 | *€ 152.52* | *€ 78.92* | *€ 63.70* |
| **Metal filter holder** | € 100.90 | *€ 106.27* | € 60.99 | *€ 427.65* | *€ 139.95* | € 52.50 |
| **Retainer clip** | € 40.00 | € 13.27 | € 13.53 | € 32.06 | € 32.43 | € 9.10 |

**Table 1. Quoted prices for three mock-up parts of the Dyson V11. The cells marked in grey are more expensive than the OEM replacement.**

## Discussion

For this vacuum cleaner, 67 out of 139 unique parts were considered eligible for printed spare parts, even if a digital file is present and all printability-limiting criteria are overcome. Only 33 out of 139 parts scored very highly (8 or 9) in printability criteria. Multiple limiting criteria were encountered for most parts. Although the analysis only considered a single product, this product can be considered exemplary for many household appliances that use injection moulded plastic and multi-material parts, and that group parts in inaccessible (sub-)assemblies. Also, the multitude of materials used poses challenges to direct fabrication with AM as the manufacturing of such parts cannot be easily transposed. This implies that supplying spare parts through local AM requires either adaption in the product design to produce parts with both AM and conventional manufacturing, or that manufactures supply a digital file for AM that allows the printing of a functionally equivalent (but different) part.

Considering the method of establishing printability by assessing limiting criteria, Figure 4 shows that the criteria helped clearly distinguish between more printable and less printable parts. However, we observed that several parts were sensitive to printability issues despite a high score. This leads to additional criteria like flexibility/elasticity, compressibility, and multi-material composition (as with overmoulded parts). The highest-scoring parts were foam gaskets, which could also be produced by laser cutting sheets, so AM was not a unique enabler for their replacement.

The price of printed parts appears similar to the price of spare parts obtained through the OEM, but this is partly because the OEM requires consumers to buy a complete (sub-)module instead of just the needed part. Thus, AM spare parts are likely to be significantly more expensive than original spare parts for companies that do allow the purchase of individual spare parts. However, these economics could change for older products for which parts are rare.

Even if manufacturing AM spare parts is possible, quality guarantees will be needed. To ensure that printed spare parts are reliable, sustainable, and safe, some form of quality control and certification should be established, either through the OEM or AM service providers.

*Limitations and recommendations*

This study was limited by several factors. Part testing only considered the fit and short-term performance of the AM part, which makes it difficult to determine limiting criteria of long-term part performance. Also, only small parts were printed in metal, which could affect affordability for larger parts. Additionally, using an AM service provider meant that there was limited insight into the printing process, costs, and lead times. Industry can be expected to face the same challenges, but on the other hand, they can strive for more insightful collaborations.

For future research, we recommend further research into part printability to refine the current list of limiting criteria. As mentioned above, material properties like flexibility/elasticity, compressibility, and multi-material should also be considered. Additionally, research can focus on design strategies to overcome the challenges indicated by the limiting criteria. We also recommend further research to find the crossover point where AM of spare parts becomes preferable to conventional production, both environmentally and economically. To this end, we recommend that industry and OEMs focus on enabling AM of spare parts when designing the original part. Finally, additional developments in legislation and certification are needed to ensure that spare parts are safe to use.

## Conclusions

Based on these results, we conclude that printed spare parts can be affordable, but that only a small selection of parts is suitable for additive manufacturing. Overall product complexity and part requirements such as fine details and accurate fit can make it difficult to reproduce parts without considerable redesign efforts. We also identified additional criteria for assessing part printability, which are elasticity and flexibility, compressibility, and multi-material. As additive manufacturing methods continue to develop and improve, it can be assumed that printed parts will become more accessible and affordable in the future.

Products should be designed for repair, and designing parts for printing on-demand can be part of this. Printing on demand means manufacturers could limit their stock of less-common parts, keep costs low, and have spare parts available long after warehoused parts would be economically prohibitive. Currently, a relatively small percentage of spare parts can be printed, but this could be fixed with redesign for printability (or if alternative printable spare parts are designed). Designing for repair is one of the many requirements to produce sustainable consumer products.

## Acknowledgments

This research is part of the Sharepair project, which has received funding from the European Commission – Interreg NEW project number NWE982.

# The state of clothing donations and its links to overconsumption of fashion – case of Geneva, Switzerland

**Katia Dayan Vladimirova**[a], **Marlyne Sahakian**[b]
a) University of Geneva, Geneva, Switzerland
b) University of Geneva, Geneva, Switzerland

**Keywords**: Fashion; Consumption; Social change; Waste.

**Abstract**: This paper is based on the results of a two-year project that took place in Geneva between 2020 and 2022. The research aimed to investigate existing sustainable fashion initiatives in the city with a focus on collaborative fashion consumption, including second-hand resale, swapping, and rental. Applying the conceptual lenses of the Multi-Level Perspective and Social Practice approaches for understanding social change, this paper explores 'sustainable' fashion niches or proto practices as potential rivals to 'unsustainable' fashion consumption practices.

Through participatory research methods, interviews, and observations across thirty locations and events over the course of the project, it was possible to describe existing practices while also uncovering the current landscape of actors and power dynamics. The key focus of this paper, which presents a subset of the findings, is on clothing donations and the second-hand resale circuit in the city. Findings reveal complexity and opaqueness of the post-consumer textile value chain, which is heavily oriented towards exports. The research identifies a number of lock ins and opportunities for local actors, including municipalities, charities, educational institutions, NGOs and SMEs, to support the development of sustainable fashion initiatives compatible with circular economy principles.

## Introduction

Over the past twenty years, global production of clothing and textiles has more than doubled (Ellen McArthur Foundation, 2017). With a population of 10 million people and second after Luxembourg for achieving the highest per capita expenditure on clothing and shoes in the world (Statista, 2021), Switzerland is an important market for non-luxury fashion retailers. However, data and research on fashion consumption and disposal patterns in the country and across the different Swiss cities has been lacking.

A two-year research project analysed the situation in Geneva, a city in the francophone part of Switzerland with a total population of ca. 1 million (including neighbouring France) – an important centre of commerce, including clothing and fashion retailers. This study focuses on a sub-set of the findings that concern the fashion system downstream from production and consumption, and specifically how unwanted clothes and textile waste are managed within the city by different actors. The goal of this paper is to improve our understanding of the ecosystem of post-consumer textiles and fashion in relation to material flows.

## Theoretical Framework

To analyze social change, different theories can be relevant as a framework through which the production and consumption of apparel and textile can be understood, and promising initiatives might be supported. We propose both the Multi-Level Perspective (MLP) and Social Practice Approach (SPA) as complementary theoretical frameworks.

This innovative double-lens approach (see Keller et al 2022 for a comprehensive review) allows to investigate the phenomenon in more detail through each framework, while leaving room for a criss-cross analysis between the two to identify system lock-ins that can be easily missed by doing two analyses separately. Moreover, this approach allows us to explain not only the status quo but also discuss possibilities for social change and a transition towards more sustainable ways forward.

*Multi-level perspective*

From transition theory, the MLP is interested in dynamics between three different levels (or scales): landscape, regime, and niche. The landscape represents the broadest scale, including socio-economic and political dimensions that can be seen as structural contexts. The intermediary scale is the regime: at this level, established actors maintain a status quo based on interactions between the economic market, available technologies, culture and social norms, and existing policies or rules and regulations. Niches represent the third level of analysis; these are emerging initiatives that have an innovation at the core and could have the potential to disrupt existing, dominant regimes. Niches are weak and require protection until they mature enough to pose real alternatives to the dominant practices of the regime they are contesting.

In an early work by Geels, the main author of the MLP, this framework was used to understand how automobiles came to displace horses and carriages in 19th century North America (Geels, 2005). In that example, horse carriages were the regime, and the automobile was a niche. In our case, fast fashion is an established regime, and slow and sustainable fashion is a niche. In order to destabilize a regime, a niche level innovation might need State support, but could also benefit from changes in landscape dynamics. The Fukushima disaster was a landscape dynamic that incited a wave of support for phasing out nuclear energy in Europe, for example. In the case of fast fashion, the collapse of Rana Plaza factory in Dhaka, Bangladesh served as a similar force.

*Social Practice Approach*

The Social Practice Approach (SPA) builds on social practice theories, which propose a framework for understanding everyday life as embedded in what people do. When applied to consumption studies, the focus is often on the routines and daily lives of people, or mundane activities. Rather than see individuals as having agency, this perspective sees agency as distributed across different elements of practices, involving material arrangements and things, meanings, and other forms of social norms, as well as skills and competencies of people who are considered to be "carriers" of practices (building on Shove et al, 2012).

While social practice theory can be used to describe existing practices, it has also been applied to understand how interventions in practices might be effective, towards more sustainable outcomes (Hoolohan & Browne, 2020). According to Sahakian and Wilhite (2014), changing a practice implies changing at least two out of its three elements. Social practices in themselves contain the "seeds of change" (Warde 2005). SPA distinguishes between social practices and systems of social practices that are more established, and proto practices that are emerging and are not yet widely accepted – making the approach compatible with the MLP, as a recent review of the literature has demonstrated (Keller, Sahakian & Hirsh, 2022). MLP and SPA share many similarities and can work hand-in-hand to uncover issues and system lock-ins that are less evident when applying MLP and SPA separately (Seyfang & Gilbert, 2019).

## Findings

*Situation in Switzerland*

The Swiss apparel market in 2021 had a total revenue of ca. 11 billion CHF (Statista, 2021). Women's clothing represents the largest market share (about 57% in 2019) and 90% of sales in the clothing market are attributable to non-luxury products in 2019 (Statista, 2021). The share of sustainable apparel has been consistently growing over the past years; however, it remains quite low, around 6% of the total apparel market (Statista, 2021).

In 2019, Switzerland imported ca. 184,325 tons of new clothes, footwear, and home textiles in 2019 (30% from China, 13% from Bangladesh, 10% from Germany) (AFD, 2021a). The share of clothes manufactured in Switzerland contributes to roughly 3-5% of clothing consumption in the country (Swiss Textiles Coalition, 2022). In total, consumption levels come up to 193,541 tons, or ca. 22.6 kg per capita, in 2019[1]. To summarize, Switzerland imports over 95% of the clothes and textile fashion products.

[1] Year 2019 has been chosen as a pre-COVID-19 level of consumption. consumption levels in 2020 and 2021 have been artificially lower due to the pandemic.

Furthermore, in 2019, Switzerland exported ca. 96,324 tons of clothes, footwear, and household textiles (AFD, 2021b) – including 68,357 tons (71%) of used products in these categories, which roughly amounts to 8 kg per person. This per capita amount does not include garments that are recirculated locally and direct disposal of worn-out textile products and shoes to unsorted waste bins. These numbers indicate a quick turnover and a high material throughput in household apparel consumption (AFD, 2021b).

An analysis of the Swiss exports statistics indicates that export destinations for used garments are primarily in Europe (Germany and Eastern European countries). Less than 10% of garments are exported directly from Switzerland to the African countries.

### *Situation in Geneva*

The Climate Strategy of the City of Geneva (2022) acknowledges the importance of overconsumption of clothes as one of the priorities to address as part of measures to mitigate climate change. In 2019, Geneva consumers purchased around 23,200 tons of garments, footwear, and household textiles.
Meanwhile, every year unwanted clothes, footwear, and accessories end up as charity donations. In 2022, a local association *Coordination Textile Genevoise* (CTG) – that has an exclusive mandate from the City of Geneva and the communes to collect used clothes – received around 2,740 tons of clothes, footwear, accessories, and household textiles. Roughly 2,225 tons are collected via donation containers and ca. 500 tons are brought by individuals directly to charities. Donations though clothing containers have increased dramatically, from 250 tons in 1994 to 2,225 tons in 2022.

Charities in Geneva sort and redistribute approximately 915 tons of donations locally, including 100% of what is received as direct donations and part of what gets donated through containers, which gives a local sorting ratio of 33% of the total volume of donations. To sort and resell donations, charities work with volunteers and people in professional reinsertion programs who are not necessarily specialized nor professionally trained for this work (other than through practical training on the job). High quality donations in good condition are resold through 22 local charity shops or given directly to people in need, locally, through an initiative called *Vestiaire Social*. Average quality donations in fair condition are typically sold to Texaid, a commercial reseller, and those of low quality and in poor condition are locally incinerated.
In 2022, an association *Vestiaire Social* stocked and redistributed approximately 120 tons of textiles to people in precarious situations (roughly 4.3% of the total volume). Some of the donations, due to low quality, are discarded into general waste bins (there is no precise data due to the shortage of human resources, which prevents the association from consistent tracing). Unfortunately, there is also no precise data available on the volume of textiles that are directly discarded by consumers into unsorted waste bins, including at the Geneva City Waste Department.

Among four textile sorting facilities, Geneva charities do not have the physical capacity to sort the increasing volumes of donations. More than 60% of all donations in the city are sold in closed bags to Texaid, a German-Swiss company that has an exclusive contract to buy second-hand apparel from charities in Geneva. Selling donated clothes allows to finance part of the social projects of the charity associations. However, over the past 5-10 years, there has been a decrease in second-hand prices due to the rising offer globally. Texaid sorts and further exports most of the second-hand garments, shoes, and household textiles out of the country (Texaid, 2017).

Geneva clothing donations are known for their quality, which is a direct result of the wealth present in the city and the high purchasing power of Geneva consumers. However, the high-quality finds are becoming more and more rare as the overall volumes increase. Geneva donations today are comprised primarily of garments from fast fashion, non-luxury brands in relatively good condition. Sometimes donations contain clothes from ultra-fast fashion brands, like Shein, Boohoo, or Pretty Little Things, that are brand new, with tags — and occasionally in multiple sizes. This might be explained through the consumer practice of buying a model in several sizes to choose the one that suits them best and put the rest directly into donation boxes, because of the low prices. The quality of these garments (cut, fabric, finish) is low, and their lifespan is short. Unlike good quality clothes, these pieces usually don't last more than a few washes.

Consumers are increasingly turning to donation boxes to get rid of clothes they no longer want, including worn-out pieces that can no longer be recycled. Clothing donation bins are often located next to recycling bins for plastics, paper, and glass, leading to confusion when it comes to textile donations. While charity donation bins clearly state that deposited clothes should be clean and in good condition, sorters also regularly find textile waste, sometimes wet textiles, which contaminate the whole batch.

## Discussion

Applying the theoretical lens of the MLP, the situation with second-hand fashion market and post-consumer textile waste in Geneva can be viewed as a result of a dominant regime of fast fashion and weak influence of the niche occupied by sustainable fashion initiatives. At a level of a country, the fast fashion regime has fueled unprecedented levels of material throughput that involves third countries. Switzerland imports new fast fashion garments from China and Bangladesh and exports second-hand garments to Eastern Europe and Germany.

This last finding is in line with the recent report by the European Environment Agency (2023), which identifies Germany, Netherlands, Italy, and Poland as the key hubs aggregating second-hand textiles from other European countries for further sorting and exports. However, European exports of second-hand garments to Africa have increased three-fold over the past ten years (UN Comtrade, 2021). Even if second-hand clothes enter the resale market in Switzerland and are initially exported to other European countries, eventually a larger part of these material flows end up in Africa as part of the European second-hand apparel exports.

While the second-hand market undoubtedly helps extend the useful life of clothing, any garment, shoe, or bag eventually reaches its end of life. Exporting used clothing and textiles is not a solution to overconsumption: at some point, the last user will dispose of them. In this respect, it is important to track where the clothes that have acted as donations are sent, as this will have major implications for their eventual fate and the extent of their negative environmental and social impact as waste.

### *Urban waste regime and clothing disposal practices*

At a city level, the fast fashion regime has benefited from the inconsistencies in the urban waste management regime, which has been absorbing excess and obscuring the true scale and impacts of overconsumption. Emerging collaborative fashion proto practices, such as second-hand shopping, swapping, or rental (Henninger et al, 2021) are contesting the regime by promoting local reuse as opposed to “throw-away” culture of clothing donations typical to fast fashion. Actors behind such initiatives have reported a number of challenges, including the need to educate consumers about the true cost of garments (aligned with meanings embedded in social practices), and support new competencies around second-hand shopping.

There is also a disconnect between local charities, a powerful actor exclusively responsible for managing clothing donations in the city, and independent second-hand shops. Local boutiques do not have access to key donations and have to search for merchandise elsewhere, while the largest bulk is sold wholesale to commercial resellers and exported out of the country.

Another sustainable fashion proto practice, mending and repairs, is also negatively affected by the existing urban waste regime, as it enables a throw-away mentality among fashion consumers. Lack of regulations and action around separate textile waste collection create a situation in which consumers have a “free pass” to continue buying and getting rid of clothes, in good consciousness – thinking they are donating their garments to a good cause.
In Geneva, charities remain the key actors directing post-consumer textile material flows. *Coordination Textile Genevoise* lacks infrastructure and material arrangements to deal through the ever-increasing volumes, as well as trained personnel with sorting competencies, to increase local reuse.

Infrastructure and technology for fiber-to-fiber recycling are only starting to emerge, in experimental pilot projects, and primarily in Europe, but less than 0,5% of second-hand textiles is recycled in this manner globally

(Textile Exchange, 2022). At the end of life, textiles in Geneva are burnt in incinerators (where synthetic fibers emit toxic chemicals). When exported to other countries, end-of-life textiles are also found in open landfills, as well as water streams and oceans (where non-biodegradable synthetic fabrics prevent other compostable matter around them from biodegrading by blocking access of oxygen).

The current economic model behind fashion consumption remains relatively linear. More could be done to achieve circularity and slow down the ever-increasing consumption pace and volumes. To take responsibility for overconsumption as opposed to externalizing its impacts onto vulnerable populations in developing countries, it is imperative to increase local sorting and reuse substantially and limit exports of textile waste as much as possible. It is equally critical to lower the consumption volumes of new clothes.

## Conclusions

In recent years, much attention has been paid to human rights violations and environmental pollution in fashion supply chains, mainly in Asian countries. Low prices of garments that externalize social and environmental costs have been blamed for fueling overconsumption. This study indicates, based on the case of Geneva, that the downstream side of the fashion system also enables overconsumption. Opaque post-consumer value chains hide the environmental and social impacts by exporting unwanted clothes to other countries. Consumer culture around fashion which celebrates “more” as “better” relies on externalizing both production and disposal impacts of overconsumption.

However, emerging sustainable fashion practices are challenging the dominant regime of fast fashion and, with the right support, may transform the system towards more responsible rails.

## Acknowledgments

We would like to thank the Agenda 21 department of the City of Geneva for its support of this project through the G’innove funding scheme.

# Gender roles as barriers to sustainable fashion lifetimes: How a deconstruction of norms can extend the use phase of garments

**Stephan Wallaschkowski**[a,b]
a) Leuphana University Lüneburg, Germany
b) Bochum University of Applied Sciences, Germany

**Keywords**: Sustainable consumption; Fashion; Gender roles; Barriers; Sufficiency.

**Abstract**: The rise of fast fashion has led to a significant decline in the product lifetime of fashion items and a serious increase in the socio-ecological issues caused by the apparel industry. For a genuine sustainability transition, it is thus important to (re-)extend the individual use phase of garments. Recent studies have revealed large sex differences, though, with women consuming more fast fashion items while keeping single garments for a shorter time span. Against this background, my study explores the underlying reasons for these differences in order to identify gender-specific barriers to sufficient clothing consumption, particularly in women, based on the theory of 'doing gender'. For this purpose, 15 focus groups were conducted which revolved around 'masculine' and 'feminine' ways of acquiring, using and disposing of clothing items, and the appropriateness of sufficiency in fashion in light of these gender roles and accompanying behavioral expectations. My findings reveal a strong association between intense fashion consumption and 'femininity', indicating that consuming clothes sufficiently is the appropriate 'doing gender' for men while the opposite holds true for women. Accordingly, a lot of female participants report strong internal and/or external pressures to consume in line with this gender role, not felt the same way by male participants. These drive gender role conformity and create the observed sex differences. To mitigate these internal and external pressures, the best option is a deconstruction of the gender role of the 'female fashionista'. Since this is a long-term endeavor, short term measures, that support women in consuming clothes sufficiently despite expectations to contrary, are needed, too.

## Introduction

In the past twenty years, consumption of garments globally has doubled and use time halved, due to the rise of fast fashion (Gazzola et al., 2020). This has led to a serious increase in the social and ecological issues caused by the apparel industry, like water depletion, soil exhaustion, chemical pollution, exploitation of labor, and many more (Niinimäki et al., 2020). For a sustainability transition of this industry, it is thus imperative to extend the product lifetime of garments again – and one crucial aspect in this regard is to promote sufficient consumption by prolonging the individual use phase of fashion items.

Recent studies have shown that there are large sex differences, though, with women being much more devoted to fast fashion than men, acquiring more garments in general and fast fashion items in particular, while keeping single pieces of clothing for a shorter time span before discarding them (Wallaschkowski et al., 2022). This suggests that a gender-sensitive approach to the promotion of sustainable fashion lifetimes is needed. However, not much yet is known on the underlying reasons for these differences and, thus, on how to address men and women appropriately according to their gender-specific obstacles to sufficient fashion consumption and a prolonged use phase of garments.

Against this backdrop, the aim of this study is to explore gender-specific barriers to sustainable product lifetimes in the use phase of garments based on the theory of 'doing gender' (West & Zimmerman, 1987). This theory attributes sex differences in behavior to people's adherence to gender roles in society, that is socio-cultural perceptions of 'masculinity' and 'femininity'. Accordingly, my research questions are: What are typical notions of 'masculine' and 'feminine' ways of acquiring, using, and disposing of clothes? How do these gender roles give rise to the observed sex differences in consuming fashion sufficiently? How can gender-specific barriers to sufficient fashion consumption be overcome, particularly in women?

## Theory: 'doing gender'

Gender studies reveal biological arguments to be insufficient for explaining sex differences in behavior (Eagly & Wood, 2013). They suggest that they also stem from common conceptions in terms of typical 'masculine' and 'feminine' characteristics (Lippa, 2005; Wood & Eagly, 2002). People internalize these in the course of their socialization and integrate them (more or less) into their self-concept as man or woman (Cross & Madson, 1997; Cahill, 1986). Likewise, they use them as prescriptive standards to assess other's behavior as appropriate or inappropriate for their sex (Prentice & Carranza, 2002; Heilman, 2001; Burgess & Borgida, 1999). Accordingly, gender roles are strong personal and social norms for people's actions (Rudman & Glick, 2008).

Gender studies therefore distinguish 'sex' from 'gender'. While 'sex' separates between men and women on a mere biological basis, the term 'gender' refers to the cultural connotations that are associated with 'masculinity' or 'femininity'. According to this definition, 'gender' is not an innate quality, but a social construction (Lorber & Farrel, 1991). It becomes a personal attribute only by the process of 'doing gender', that is the constant indication of one's sex category in social interactions through the ongoing display of gender-stereotypic characteristics and the regular performance of gender role appropriate behaviors (West & Zimmerman, 1987). This process is driven by the implicit norm prevalent in many societies that one's sex category must be always identifiable, which can only be achieved by a role compliant gender expression (activities, habits, mannerisms that are deemed 'masculine' or 'feminine' culturally), since the genitals are usually covered. It can be so deeply internalized that people act consistent to their gender role even when nobody else is present. The actual performative nature of gendered behaviors normally remains unnoticed for this reason, which is why they often appear to be natural – but cross-cultural comparisons unveil that they are not (Brettell & Sargent, 2017).

From this point of view, gender roles can build barriers against the adoption of sustainable consumption patterns if those are considered not suitable for a gender expression in accordance with one's sex category or, the other way round, if unsustainable consumption patterns are an integral part of the respective gender role. White and Dahl (2006) have already demonstrated this for product choice in general and Brough et al. (2016) have shown that it holds true for green purchase behavior as well. Accordingly, it is reasonable to expect this for the case of sufficiency in fashion, too.

## Methods

As little preliminary work on sufficient fashion consumption from a social constructionist gender perspective has been conducted, a qualitative research approach was applied. Qualitative data provide thorough descriptions of social phenomena as seen from individuals' perspective, allowing respondents to highlight their own structures of meaning and thus giving in-depth understanding of their social reality construction (Flick, 2018). I employed focus groups as the technique for data gathering in particular since it has proven to be productive for discovering gender roles in other contexts (e.g., Madriz, 1997; Mermelstein, 1999;). Its advantage for this purpose is that group settings, especially with strangers, encourage reference to socio-cultural norms like prevalent images of 'masculinity' and 'femininity' (Bloor et al, 2001).

15 focus groups with a total of 127 men and women from Germany were carried out. Each followed a semi-structured discussion guide and was moderated observing established directives (Krueger & Casey, 2015). Topics concerned participants' views on 'masculine' and 'feminine' ways of acquiring, using and disposing of clothing items, and the perceived appropriateness of sufficiency in fashion for men and women in light of these gender roles and accompanying behavioral expectations. The discussions lasted from two to three hours. Afterwards, all participants completed a Bem Sex-Role Inventory in its latest German version (Troche, & Rammsayer, 1988) to assess their gender role orientation.

All groups were voice recorded and transcribed verbatim. Following a qualitative research logic, the transcripts were iteratively subjected to a thematic analysis (Braun & Clarke, 2006) and additional groups were created until theoretical saturation was reached.

## Findings

*Stereotypes of ‘masculine’ and ‘feminine’ consumption styles in fashion*

To identify prevalent gender roles in terms of ‘masculine’ and ‘feminine’ ways of fashion consumption, we asked our participants to discuss and jointly depict on a form sheet (Figure 1) how in their opinion men and women typically acquire, use, and dispose of clothes. A comparative analysis of these passages on the group and intergroup level revealed the following shared views and conceptions.

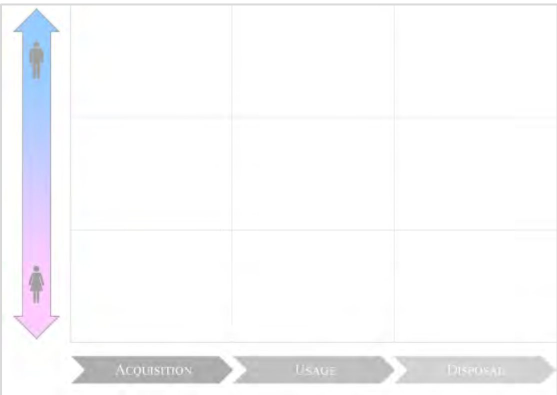

**Figure 1. Form sheet to illuminate gender roles.**

Regarding acquisition, women were portrayed as being highly intent on their appearance, very interested in fashion and liking to go shopping frequently. For them, shopping is a “leisure event that doesn’t need a special occasion”. Their purchase behavior is “impulsive and lust driven”, leading to a constant and high demand for new garments. Hence, they usually tend to buy rather cheap and are particularly attracted by low-cost fast fashion. Due to the bulk, they buy, their spending on clothes is nonetheless high. Men, on the contrary, are assumed to not pay so much attention to their appearance and have little interest in fashion. For many, it “does not matter what they wear, providing it is fitting and comfortable.” Shopping is a chore for them, which is only done if necessary. Consequently, they heed quality and durability and are willing to pay a higher price for it. Despite this greater willingness to pay per piece, their total clothing expenses are still lower as with women, in our participants view.

In the area of usage, women are believed to make great effort when choosing their outfit and to take care not to wear the same several times in a row. Because of their pronounced trend orientation and the continuous replenishment, single garments are donned much less frequently than in males and discarded more quickly. Some items are used only once or twice, some even remain untapped forever. By contrast, our interviewees perceive men as more pragmatic in dressing. Usually, they stay with a style for a long time and wear their clothes more recurrently and permanently than females. Most items are used until they are worn out.

When it comes to disposal, women are assumed to sort out garments when these no longer please, are no longer fashionable, or when they just have so many new articles that they would not don the item anymore. Most of these pieces are still perfectly fine because of the low usage intensity. That is why many women want what they discard to be lovingly reused. Accordingly, cast-off or surplus clothes are donated to charity, given away, exchanged with friends, upcycled, or resold. Conversely, men only sort out what has become shabby or does not fit anymore. Damaged or torn items are thrown away or taken to recycling. Flea markets, clothes swapping, resale etc. usually do not matter to them.

It is important to mention, that these are first of all gender roles reconstructed from participants’ statements, that is behaviors considered typical for men and women. However, according to the theory of ‘doing gender’ it can be expected that these ultimately materialize in actual behavioral differences. This is evidenced by the study of Wallaschkowski et al. (2022), who showed that men’s and women’s average consumption patterns in fashion are broadly in line with these stereotypes. As per Giddens’ (1984) theory of structuration, this steady transfer of gender roles into visible actions leads to their constant reproduction as personal and social norms, so that both become circularly reified as socially constructed reality.

In conclusion, one important reason why men consume fashion more sufficiently is that this is just the appropriate ‘masculine doing gender’ while the opposite holds true for ‘femininity’.

*Internal and external pressures to gender conformity in fashion consumption*

In line with this reasoning plenty of my female participants, in particular those with a marked gender role orientation towards 'femininity', depicted clothing consumption as an important part of their 'feminine' identity. They consider it "normal for real women to be intent on their appearance" and to dress well according to the latest fashion and describe this as some kind of "instinct that every woman has". Accordingly, they regard shopping for clothes as an activity "that simply goes with being a woman". Some even report an "inner urge" to shop frequently and present their behavior in fashion stores as driven by their subconscious mind without them being able to control it ("I walk into a fashion store and ... oops... suddenly the bag is full. No idea how that happened."). Thus, many women would find it "hard" or even "against my nature" to consume clothes more sufficiently. This illustrates, how the association of 'femininity' and fashion can get so deeply internalized as a personal norm that its role as behavioral standard is 'naturalized' and its performative nature is denied. Instead, it is felt as internal pressure beyond conscious control.

Of course, the strength of people's gender role orientation can vary and not all of my female participants were geared towards 'femininity' in this intensity. Correspondingly, there were also female participants who were not interested in fashion. Interestingly, they often revealed this as some kind of confession of not being normal ("I think I'm a bit unusual, but I'm not so much interested in fashion."), which shows that they are well aware that the opposite is expected of them. Besides, they depict how this expectation can drive their consumption even if they don't want to. One young woman revealed that she often joins her friends for shopping trips just to be part of the group. Another disclosed that she recently bought a new cocktail dress for a party despite having one in her wardrobe because her friends wouldn't approve her wearing the same twice.

Social pressures on their fashion consumption seem to be a common experience for many women. Several female participants brought up regularly feeling assessed by others regarding their outfit. Some delineate instances of getting a stupid line due to a 'wrong outfit choice'. One expressed the impression that women are often judged solely based on their appearance, which does not happen to men this way. ("As a woman I must look good. If not, I will be questioned as a whole. A man can look like sh… and still be regarded competent, though."). The men in this group thereupon agreed with her.

In sum, these accounts demonstrate, how the association of 'femininity' with appearance and fashion puts internal and/or external pressures mainly on women that lead them to perform a norm-confirmative 'doing gender' in this regard.

## Discussion

My results show how gender roles in the matter of acquiring, using, and disposing of clothes act as barriers to sustainable product lifetimes; in particular in women, where sufficient fashion consumption doesn't fit the socially constructed expectations. These drive women to consume fashion intensively either by means of internal pressures caused by their internalization or by way of external pressures due to sanctioning of nonconformity. Both result in the well observed sex difference in the average volume of clothing purchases and the accompanying shorter use phase of single garments with women.

In order to address this gender-specific barrier to sustainable product lifetimes in fashion, two general directions are conceivable. In the long run, the best option is the deconstruction of the gender role of the 'female fashionista' that leads to the expectation that women must be intent on their appearance and dress fashionably for an appropriate gender expression. This goal is ambitious, however, as the social construction of reality is a systemic process that defies direct control (Berger & Luckmann, 1966). Extensive, regular perturbations of this norm over years or even decades are needed. These may involve campaigns that expose the pretended 'natural' association of 'femininity' and intense fashion consumption as a mere social construction and subject it to a deliberate societal debate, maybe accompanied by new 'feminine' role models in the (social) media emphasizing that the social standing of women does not depend only on how they look, and female celebrities who have found their own style and don't join every trend, among others.

In the short run, however, this gender role is the social reality that women face in our society. So, the question is, how to mitigate the internal and external pressures with respect to their clothing consumption despite being exposed to contrary personal and/or social norms – until these are eventually deconstructed. One way could be to raise awareness of the eco-social side effects of excessive fashion consumption. It is a well-known issue, yet, that awareness raising does not necessarily translate into behavioral change (Carrington et al., 2014). Another way, or useful addition, might therefore be nudges that trigger sufficiency when consuming clothes.

## Conclusions

The prevalent gender role associating 'fashion' with 'femininity' drives women's intense fashion consumption and hinders them from consuming clothes more sufficiently. Its deconstruction can thus help to prolong the individual use phase of garments and (re-)extend their product lifetime. Since this is a long-term endeavor, the short-term question is how to support women to defy expectations to the contrary. A combination of awareness raising and nudging could possibly help in this regard.

**Keywords**: EDRR; Circular economy; Materials design; Cyanide-free electroplating.

**Abstract**: Traditional hydrometallurgical processes for metal production and recovery like are facing the challenges of economic and environmental concerns. Tailored electrochemistry can be considered being one of the most promising technologies to address challenges related to feasible metal recovery from dilute or impure solutions. The direct usage of clean electricity during electrochemical metal recovery can decrease the use of $CO_2$ intensive chemicals and achieve higher holistic energy efficiency as losses due to chemical synthesis or preparation steps can be avoided. Recently, an innovative electrochemical method – electrodeposition and redox replacement (EDRR) – was proposed by the research group of Hydrometallurgy and Corrosion at Aalto University, for the valorization of valuable elements with trace concentration from hydrometallurgical solutions. To date, the recovery of silver, gold, platinum, and tellurium with low concentration (mg/L or µg/L level) from various complex hydrometallurgical solutions by EDRR have been investigated. Moreover, recent studies have demonstrated the versatility of EDRR to product high value-added metallic materials like nanoparticles, dendrites and alloy coatings. Unlike traditional electrodeposition, the EDRR method does not involve any complexing agents and the currently underutilized hydrometallurgical solutions or waste streams can be used as liquid raw materials in the production. All these previous studies suggest EDRR as an innovative method and a promising approach to achieve efficient metal recovery and/or sustainable direct manufacturing of metallic coatings. In this paper, the advances of the application of EDRR are summarized to highlight electrochemistry as a tool for improved circular economy of metals.

## Introduction

The demand of metals is ever-increasing due to more widespread industrialization, green transition and electrification as well as greater use of consumer electronics, whereas high-grade metal-containing raw materials are depleting (Brooks, 2018). Consequently, the global scarcity of metal resources that has become impending concern. For instance, silver production is expected to reach its peak in 2030 and the supply of silver will also be soon at risk by 2075 because of the increasing demand and limited availability (Sverdrup et al., 2014). Compared to silver, other precious metals like gold and platinum group metals (PGMs) have even lower natural abundance and therefore are facing a severer resource crisis in the world (Dong et al., 2015). Hydrometallurgical processes are applied in metal production in increasing amounts. Unit processes in hydrometallurgical processing focus on target metal dissolution via leaching, metals separation and purification via solvent extraction, ion exchange and sorption, or final metal product recovery from produced solutions by electrowinning, chemical reduction, precipitation and cementation (Free, 2021). Nevertheless, the application of these methods is increasingly challenged by the related economic and environmental concerns, especially when more complex/dilute solutions are being utilized in metal production. To achieve the goals of sustainable development, the development of innovative and environmentally friendly technologies and the high-efficient utilization of different raw materials has become increasingly critical in metal industry.

When using hydrometallurgical processes to produce base metals like copper, zinc, nickel and lead, impurity elements including precious metals (gold, platinum, silver, etc.) may also be present in process solutions, along with the base metals, due to their coexistence within the ore bodies (Crundwell et al., 2011; J. E.

Dutrizac, 1985; Mulwanda & Dorfling, 2015; W. Wang et al., 2020; Xing et al., 2018). Due to their low concentrations (< mg/L or even < µg/L), such impurity elements present in these types of hydrometallurgical solutions are difficult to recover using the current-existing hydrometallurgical processes. Innovative electrochemistry may provide a platform for the cost-effective and environmentally friendly utilization of these elements. Since the first application of producing metallic sodium (Na) from molten sodium hydroxide (Davy, 1997), electrowinning- a classical electrochemical method - has become one of most widely used technologies in elemental metal production such as zinc, copper, silver, lead, etc., from various media (Free et al., 2012). However, traditional electrowinning is facing the difficulties to recover metals with minute concentrations due to the limited mass transfer rate. To better exploit these metals with trace concentrations, an innovative electrochemical method has been proposed by the combination of electrodeposition and redox replacement (EDRR).

In general, the EDRR process consists of two consecutive steps (i.e. ED and RR steps) that are then repeated for the desired number of cycles ($n$). Taking a solution containing silver and zinc as an example as shown in **Figure 1**, in the first step (ED), zinc ions ($Zn^{2+}$) are reduced onto a substrate through reaction 1 by an external potential $E_{ed}$ (or current $I_{ed}$) for a short time duration ($t_{ed}$). In the second step (RR), the external electricity is disconnected for a desired duration and or until the predetermined open circuit potential $E_{cut}$ are reached. In the RR step, the more-noble metal ions ($Ag^{+}$) are reduced by electrons provided by the less noble metal zinc (also called as a sacrificial metal) through **reaction 2**. The combination of **reaction 1** and **reaction 2** gives the overall reaction during redox replacement as shown in **reaction 3**. The redox replacement **reaction 3** is thermodynamically possible due to the more positive value in reduction potential of the redox pair $Ag^{+}/Ag$ has than that of the redox pair $Zn^{2+}/Zn$. Also, the potential difference ($\Delta E$) of the redox pairs involved contributes to the driving force of the redox replacement reaction as described in **equation 4**.

$$Zn^{2+} + 2e^{-} \rightleftharpoons Zn \quad Reduction\ potential\ (E_{Zn^{2+}/Zn}) \tag{1}$$

$$Ag^{+} + e^{-} \rightleftharpoons Ag \quad Reduction\ potential\ (E_{Ag^{+}/Ag}) \tag{2}$$

$$2Ag^{+} + Zn = 2Ag + Zn^{2+} \tag{3}$$

$$\Delta E = E_{Ag^{+}/Ag} - E_{Zn^{2+}/Zn} \tag{4}$$

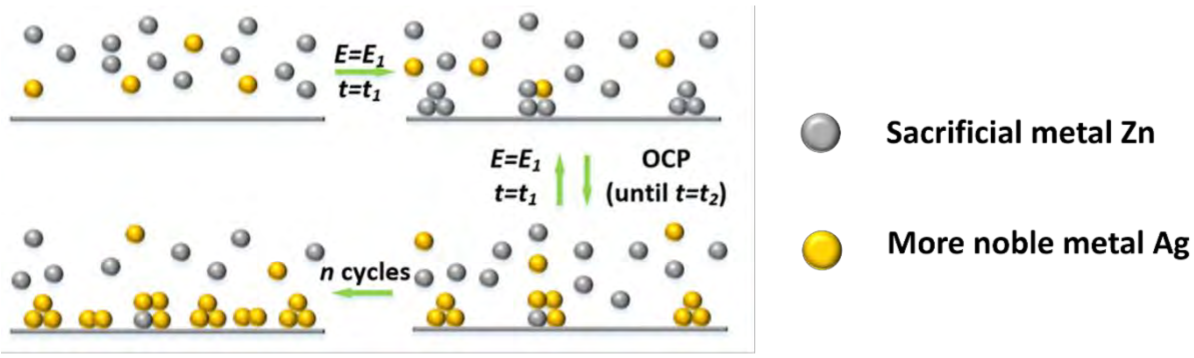

**Figure 1. Schematic illustration of electrodeposition and redox replacement (EDRR).**

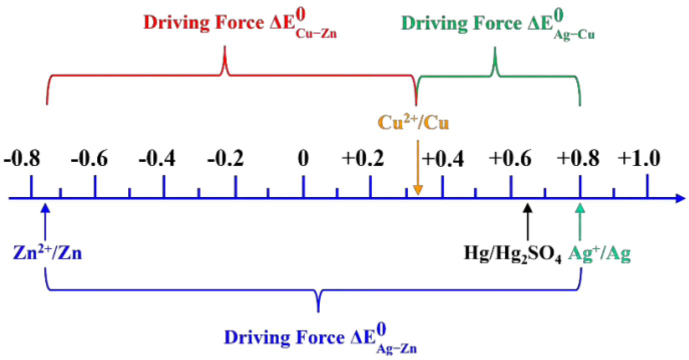

**Figure 2. Schematic illustration of the driving force (*ΔE*) between different redox pairs.**

## Applications of EDRR

### *Metal recovery*

The recovery of different valuable elements including silver, gold, platinum and tellurium from various solutions.

### *Silver recovery*

Silver and its compounds have a broad range of applications such as photography, electronics, medicines, batteries and jewellery (Syed, 2016). Typically, silver is produced as a by-product during the processing of other metals like zinc, copper, nickel, and antimony due to their coexistence is natural ores (Syed, 2016). During hydrometallurgical production of zinc, trace amount of the silver may end up in the electrolyte solution although most silver existing in the ores remains in the leaching residues due to the low solubility of silver in sulphate media (J. E. Dutrizac, 1985). Moreover, the corrosion of silver-lead anodes during the zinc electrowinning step may also results in the presence of silver in the waste electrolytes (W. Wang et al., 2020). Our previous studies have demonstrated the recovery of minor concentration of silver (as low as µg/L level) using EDRR from hydrometallurgical process solutions containing high concentration of zinc (60 - 65 g/L) (Halli et al., 2017; Z. Wang et al., 2019). Scanning electron microscopic (SEM) image presented in **Figure 3a** shows an example of the morphology of the recovered silver (Z. Wang et al., 2019). Moreover, EDRR was shown to be less energy-intensive when compared to traditional silver electrowinning (EW), especially at lower silver concentrations. However, the energy consumption during EDRR dramatically increased with the presence of high concentration of other impurities like iron ions in the solution and while traditional electrowinning is less sensitive to impurities (Z. Wang et al., 2019).

### *Gold recovery*

As a precious metal, gold has been used for throughout history in coinage and jewelry. Besides, gold has also been used in other high-tech fields like electronics and medical applications because of its colorful, lustrous, ductile, and durable properties *(Syed, 2012)*. Cyanidation has been the predominant process for gold extraction from primary and secondary raw materials due to the technical simplicity and low running costs *(Syed, 2012)*. However, the high toxicity of cyanide can bring concerns in terms of environmental, health and safety aspects. Consequently, intensive studies have conducted using various chemicals like to chloride, thiourea, glycine and deep eutectic solvents (DESs) to find the alternative lixiviants to cyanides *(Ahtiainen & Lundström, 2019; Altinkaya et al., 2020; Villemejeanne et al., 2022)*. One of the challenges for gold production using these lixiviants is the recovery of gold from the pregnant leaching solutions. Carbon adsorption and cementation have been adopted in conventional cyanidation processes. However, the chemical input in these routes may increase the operating costs and environmental burden. Our earlier studies have demonstrated that EDRR can be a promising approach to carbon adsorption or cementation. Significant enrichment of gold and high selectivity were achieved for all the media tested including chloride, glycine and a deep eutectic solvent (mixture of choline chloride with ethylene glycol) when using EDRR for gold recovery from both synthetic solutions and real pregnant leaching solutions *(Altinkaya et al., 2020; Korolev et al., 2018, 2020, 2021, 2022)*. **Figure 3b** shows the morphology of recovered gold from a chloride leaching solution using copper as the sacrificial metal *(Korolev et al.,* *2018)*. Moreover, a continuous pilot test for 150 hours was performed with industrial gold chloride solution and 83% of the gold in the solution was

recovered by EDRR onto the electrode *(Korolev et al., 2022)*. Moreover, in chloride media, the formation of $Cu^{+}$ species in the aqueous phase may also facilitate the deposition of gold. This process is called electrochemically assisted aqueous reduction (EAR) and it is also worth investigating to understand the underlying process mechanisms.

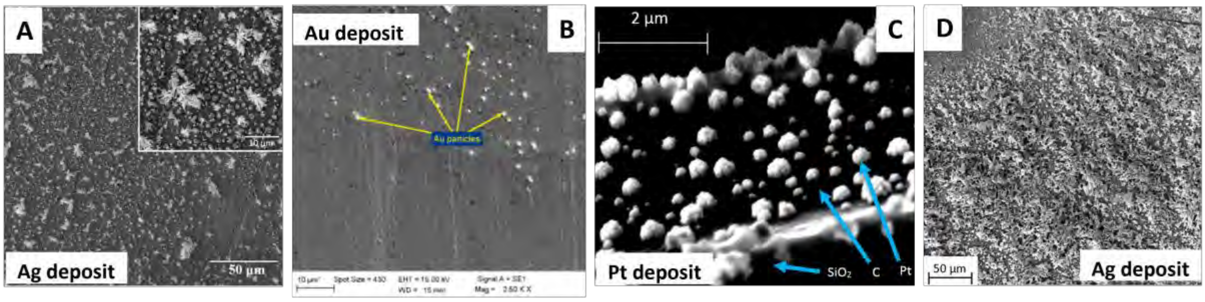

**Figure 3. Scanning electron microscope (SEM) images of metals recovered by EDRR. A) Silver. Reproduced with permission *(Z. Wang et al., 2019)*. © 2019, The Electrochemical Society. B) Gold. Reproduced with permission (Halli et al., 2020). © 2020, Springer Link.**

### *Platinum recovery*

Platinum has been widely used in the field of many industries like catalysis, electronic devices and jewellery, while the abundance of platinum in the Earth's crust is even more scarce than silver and gold *(Dong et al., 2015)*. The coexistence of platinum and nickel in natural ores results in the presence of minor concentration of platinum in nickel electrowinning electrolytes *(Crundwell et al., 2011)*. Recovery of platinum by EDRR using nickel as the sacrificial metal was tested with two real industrial process solutions that contained high nickel (>140 g/L) and extremely low platinum (<1 µg/L) *(Halli et al., 2018)*. The deposits on the electrode surface as shown in **Figure 3c** and high platinum content (90 wt %) within the particles further proves the capability of the EDRR method to recover trace concentration of metals with brilliant selectivity *(Halli et al., 2018)*.

### *Tellurium recovery*

Tellurium, as a rare element, has attracted increasing attention during its demand in a broad range of applications such as catalysis, steelmaking and especially solar cells *(Mahmoudi et al., 2020)*. In general, tellurium is mainly obtained as a by-product of processing of copper anode slimes from electrolytic refining of copper. Consequently, it is crucial to improve the recovery of tellurium from copper anode slimes to meet the growing demand *(Mahmoudi et al., 2020)*. Our previous study has proven that EDRR could be used to recover tellurium from the pregnant leaching solution of a metallurgical plant waste slag, namely Doré slag. The solution was a complex containing 421 mg/L of tellurium and various dissolved elements including sodium, barium, bismuth, copper, arsenic, boron, iron and lead (in the concentration range several g/L), as well as some other trace elements at µg/L to mg/L level *(Halli et al., 2020)*. Both traditional electrowinning and EDRR were tested for tellurium recovery and results indicate that electrowinning (EW) is favored when tellurium concentration was higher than 300 mg/L, whereas at lower concentrations the EDRR method is more competitive in terms of energy efficiency. The morphology of tellurium recovered by EDRR on the electrode surface can be seen in **Figure 3d** *(Halli et al., 2020)*.

### *High value-added metallic materials*

During the studies of metal recovery, it was found that the properties like composition and morphology of the deposits obtained by EDRR could be controlled by varying the operating parameters, which offers the possibilities to prepare various metallic materials with desired functionalities.

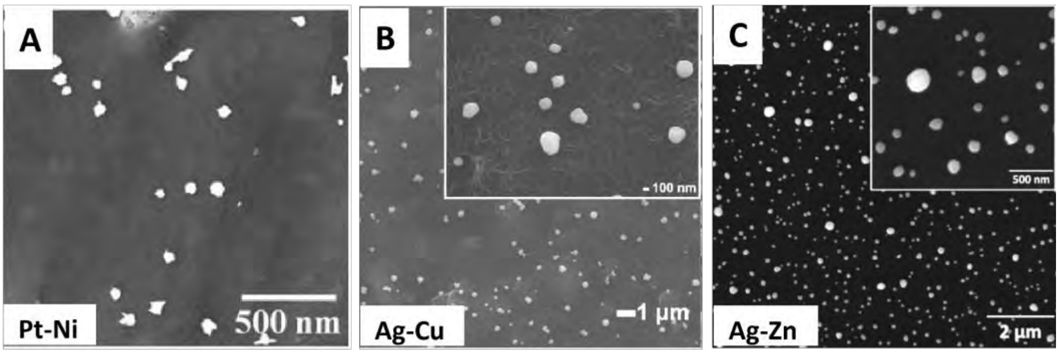

**Figure 4. SEM images of nanoparticles prepared by EDRR. A) Platinum-nickel particles. Reproduced with permission *(Yliniemi et al., 2018)*. Copyright 2018, Elsevier. B) Silver-copper particles. Reproduced with permission *(Hannula et al., 2019)*. Copyright 2019, Elsevier. C) Silver-zinc particles. Reproduced with permission *(Z. Wang et al., 2021)*. © 2021, American Chemical Society.**

### *Metallic nanoparticles*

Monometallic/bimetallic nanoscale particles are currently the subject of intensive research because of their superior physical, chemical and biological properties compared to their respective counterparts at higher scales *(Ferrando et al., 2008)*. In general, nanoscale metallic particles can be obtained either by top-down or bottom-top routes. In top-down approaches, bulk materials are sized down to nanostructures like milling or attrition. In contrast, bottom-up routes are operated via the construction of nanoscale materials from atomic or molecular precursors *(Arora et al., 2020)*. The challenges of the current-existing methods are the environmental problems accompanied with the input of additional chemicals and the increasing running expenses as the raw materials are usually high-purity metal sources. Our recent studies found that EDRR can be used to prepared various metallic nanoparticles like Ag/Cu, Pt/Ni, Ag/Zn nanoparticles (**Figure 4**) from different hydrometallurgical process solutions containing minute concentrations precious metals *(Hannula et al., 2019; Z. Wang et al., 2021; Yliniemi et al., 2018)*. Also, the properties of the nanoparticles like chemical compositions, crystalline phases and particle sizes were tunable by simple controlling the EDRR parameters. Moreover, the unique properties of the nanoparticles like tunable surface plasmon resonance behavior further demonstrated their potential applications in related fields.

### *Alloys*

Cu/Zn-based alloys, known as brass, are one of the most representative types of Zn alloys that have been used in various applications such as decoration, anti-corrosion protection, electrode materials for energy storage, shape-memory materials, and adhesion interlayers between rubber steel tire cords *(Brenner, 2013)*. Ag/Zn alloys, on the other hand, can be used as the templates for the preparation of porous Ag-rich materials for various applications *(Kurowska-Tabor et al., 2016)*. Traditionally, brass and Ag/Zn alloys have been produced using smelting-casting processes or electrodeposition. The smelting-casting process typically has a high running cost as it involves the use of high-temperature furnaces and milling facilities to obtain homogeneous mixture of metal powders. Electrodeposition is a more versatile technique that can be conducted at room temperature. However, the simultaneous deposition of Zn other metals usually involves the addition of complexing agents like cyanides and other chemicals because of the notable potential differences between different redox pairs *(Brenner, 2013)*. However, the utilization of these chemicals can increase the manufacturing expenses and environment burden. In comparison, our previous studies indicated the capability of EDRR to combine different metals with distinct potentials at room temperature without the addition of any extra chemicals as complexing agents. Ag/Zn and Cu/Zn alloys were successfully prepared by EDRR as shown in **Figure 5** *(Z. Wang, Yliniemi, Rautama, et al., 2022; Z. Wang, Yliniemi, Wilson, et al., 2022)*. Furthermore, the competitive corrosion performance of the Cu/Zn alloy coatings and the unique surface plasmon resonance (SPR) of the silver-rich materials obtained by dealloying of Ag/Zn alloys indicate their potential applications in relevant fields.

## Conclusions

This paper has summarized the advances of the innovative EDRR method in the applications of metal recovery and preparation of metallic functional materials. Compared to traditional metal recovery processes or material preparation methods, EDRR enables the better exploitation of trace concentration of valuable elements from hydrometallurgical process or waste solutions. Moreover, the EDRR process consumes only electricity while no extra chemicals were needed, which makes EDRR a promising option to reduce the environment burden to produce metals and materials especially when the renewable energy has become more affordable and easily available. Overall, the recent advances suggest that EDRR has great potential in sustainable material production and improved circular economy of metals.

# Lifespan extension of clothing products: Exploring emotional attachment to actively worn garments

**Ziqing Wang[(a)], Kristina Brubacher[(a)], Yao Yao[(a)]**
a) The University of Manchester, Manchester, UK

**Keywords**: Lifespan extension; Actively worn garments; Emotional attachment; Use phase.

**Abstract**: In the current fast fashion-dominated apparel market, the lifespan of clothing products is becoming much shorter than before. Previous research has described various ways to extend the lifespan of apparel products, but mostly from a design perspective in the pre-purchase phase. The use phase also contains a potential opportunity to develop an emotional attachment (EA) to the apparel product. With a strong attachment, consumers will be more inclined to actively wear the clothing products in their wardrobes. This helps to avoid the results of premature discard behaviour, which indicates consumer agency for clothing lifespan extension in the use phase.

Currently, more research is needed on how EA influences consumers' everyday practices and how these influences can positively impact the extension of the lifespan of apparel products. Therefore, this study takes a preliminary step to explore how EA leads to active using behaviours during the use phase. It is based on qualitative in-depth interviews and focuses on consumers' discourses about the garments in their wardrobes. Participants describe and explain their behaviours towards an actively worn item through the storytelling process. Their detailed accounts of lived experiences help to identify EA-related motivations for consumers' active use of garments they possess. This study discusses the feasibility of increasing consumers' ability to get along well with the products in their wardrobe. In terms of extending the lifespan of clothing products, the study shifts the focus from design practices to consumer behaviour in the use phase and highlights the significance of consumers in the current context of fast fashion, particularly when supported by EA.

## Introduction

The fashion industry has been dominated by the fast fashion system for decades (Pookulangara and Shephard, 2013; Liu et al., 2021; Zhang, Zhang and Zhou, 2021). It has shown astonishing responsiveness to the latest trends and produces a large range of fashionable clothing products (Bick, Halsey and Ekenga, 2018; Štefko and Steffek, 2018). Consequently, consumers are overloaded with information on accessible and affordable apparel products, which constantly stimulates their purchase intention and behaviours (Harris, Roby and Dibb, 2016; Shim, Kim and Na, 2018). They quickly get bored with the clothes in their wardrobe and start looking for new fashion items (Gwozdz, Nielsen and Müller, 2017). As a result, many garments are disposed of even though they are under-utilised (Lang and Armstrong, 2016; Paço et al., 2021), which results in a drastically shortened lifespan of clothing products (Niinimäki and Hassi, 2011; Degenstein et al., 2020; Klepp, Laitala and Wiedemann, 2020).

Previous studies have mentioned various methods of extending the lifespan of clothing products, for instance, using durable raw materials and creative pattern making to guarantee quality (e.g., Hu et al., 2014; Wagner et al., 2017), or creating garments that are changeable or evolvable to adapt to the changes in people's shape or taste (e.g., Cao et al. 2014; Koo, Dunne and Bye, 2014; Rahman and Gong, 2016). Some studies suggest paying more attention to consumers and their subjective emotions, such as sensory design or co-design (e.g., Fernando and Ranasinghe, 2020; Agost and Vergara, 2020; Piippo and Niinimäki, 2021). Basically, the mainstream of the commercially available methods tries to improve products from a design perspective. However, it has been argued that the design methods have not effectively stopped consumers' overconsumption or premature disposal behaviours (Wallner, Magnier and Mugge, 2020; Kim, Jung and Lee, 2021). Some researchers also reported that consumers might have a positive attitude towards the design at first due to the novelty, but what they encounter during the use phase cannot be accurately predicted, which may lead to end of product lifespan (Mugge, Schoormans and Schifferstein, 2008; Haug, 2018). Ultimately, it is not the fashion industry but the consumers who decide when and how to use products, which determines the actual lifespan of the garments (Gwozdz, Nielsen and Müller, 2017; Weber, Lynes and Young, 2017). Therefore, the current study puts the use phase of the garments in the spotlight and tries to understand consumers' experiences and thoughts during their use of garments. Rather than continuing to design for a long lifespan, it explores the emotional attachment between people and their garments.

## Emotional attachment

From the moment of ownership, the consumer generates various behaviours towards the clothing products throughout the use phase, creating a unique relationship in the process. The relationship, also known as "attachment" (Schultz, Kleine and Kernan, 1989), is considered a specific emotional bond between people and their possessions (Simpson et al., 2019; van den Berge, Magnier and Mugge, 2021). People emotionally rely on these garments that they are attached to, thus further influencing their subsequent behaviours (Niinimäki, 2010; Niinimäki and Armstrong, 2013; Valle-Noronha, Niinimäki and Kujala, 2018; Fleetwood-Smith, Hefferon and Mair, 2019). They are more active in wearing and caring for the garments. For instance, they tend to make good use of the garments, take care of them, and repair them if damage occurs (Niinimäki and Hassi, 2011; Degenstein et al., 2020). They also have more tolerance for wear-and-tear, negative incidents, or boredom towards the garments (Kwon, Choo and Kim, 2020). They thus think carefully before ending the relationship with their clothes, which creates possibilities for further engagement and long-term use (Neto and Ferreira, 2020).

Although attachment is known to lead to consumers' active behaviour, the motivations and considerations behind need further discussion. The current study takes a preliminary step to clarify how attachment triggers consumers' active behaviours during the use phase. It provides a comprehensive understanding of the impact of emotional attachment (EA) on an individual's daily practices during the use phase through their accounts of experiences with clothing products. It is useful in helping subsequent research to further explore how to extend the lifespan of apparel products from the consumers' perspective.

## Method

Cwerner (2001, p. 87) described wardrobe as the "bedrock of intimacy, identity, and memory", which reflects the bodily aspect of one's daily life (Petersson McIntyre, 2021). A wardrobe study gathers knowledge about consumers' clothing use through interview questions (Klepp, Laitala and Wiedemann, 2020), which is suitable for the current study.

Young female consumers are more engaged with fashion and sensitive to trends (Lang, Armstrong and Brannon, 2013; Bardey et al. 2021). Thus, their clothing-related consumption behaviours are more representative and informative for studying the lifespan extension of clothing. Also, to focus on EA-related factors in the post-purchase stage, the researcher selected participants with similar backgrounds to avoid other influencing factors. Therefore, through purposive sampling, eight young female fashion consumers were invited to participate in semi-structured interviews.

Participants were asked to select one of the products from their wardrobe that they wear actively and to tell the stories of the garments in detail. As representatives of everyday products, actively worn garments have a relatively strong attachment with consumers and are more likely to evoke their memories and emotions (Neto and Ferreira, 2020; Degenstein et al., 2020). The researcher also asked probing questions for more information based on the stories. Later, the researcher transcribed the interviews and removed identifiable personal information. Participants' names were replaced by pseudonymised codes. The thematic content analysis was used to explore how EA drove a range of active behaviours during the use phase, which particularly focused on their descriptions and explanations.

## Findings

During the interviews, the participants were able to describe the actively worn garments (AWGs) they chose which are summarised in the table number 1 below.

| Table | Item |
|---|---|
| P1 | A yellow chiffon dress |
| P2 | An irregular black semi-skirt |
| P3 | Black jeans with rivets |
| P4 | A green, multi-layer halter dress |
| P5 | A black cotton jacket |
| P6 | A trench coat |
| P7 | School uniform |
| P8 | T-shirt with a logo of favourite guitar brand |

**Table 1. Actively worn garments (AWGs).**

The findings identified four themes that illustrated how EA helped consumers engage in active behaviours during the use phase. These themes were **personality**, **familiarity**, **emotion transference** and **expectation**, which are discussed below in more detail. Having identified these themes, the findings further highlighted the importance of consumers' **subjectivity** on their active wearing behaviours in the use phase.

### *Personality*

Firstly, the most obvious EA that all consumers showed is AWG's display of personality. P2 agreed that the skirt she chose aligned with her identity and she wanted to show the characteristics of 'fun' and 'strong' through the product. P4 mentioned that she felt more confident than usual when wearing her dress. This product filled a missing part of her personality and showed an enhanced identity. This was consistent with the views expressed in prior studies, which reflected a typical role of EA between people and garments is the expression of personality (Simpson et al., 2019; Legere and Kang, 2020).

Some participants tend to express their personalities to a special community or individuals. P8 told a story about how the T-shirt related to her favourite guitar brand. She wanted to be identified by those who share the same interests as her. This is different from using the product in a general context where the linkage is not recognisable to the public. Similarly, P1 said her boyfriend's positive feedback to the dress particularly made her happy. Basically, she wore it when being with her boyfriend, but sometimes also used in her daily life. However, she claimed that in the latter case she did not feel the same strong effect of personality expression. Clearly, for some products, personality is more effective when presented to certain audiences, which reflects the fact that EA could be targeted and selective in its presentation of personality.

### *Familiarity*

During the interviews, participants mentioned that they had formed habits of wearing these AWGs. The items they displayed contained a relatively long period of use. With sufficient using experience, attachment arose from a sense of familiarity. They became aware of the occasions for which the products were appropriate and the effects they might bring, thus reducing unnecessary risks of 'wearing something wrong'. The garment chosen by P7 was her high school uniform, which she continued to use with high frequency even after graduation. She made it clear that she would never wear it in public, as the item did not enhance her expression of personality. On the contrary, she had used the garment until now because it had been with her since high school and therefore felt familiar and intimate whenever she wore it. The feeling accumulated over time and formed a habit that encouraged her to maintain continuously actively use.

Also, P5 introduced a winter jacket and said that she had developed a 'dependency' on it. She explained that the dependence she showed was founded on her familiarity with the garment as she felt physically and psychologically warm and secure. This was in accordance with the previous study mentioning that clothing products with a high level of comfort are more likely for consumers to form actively worn habits (Niinimäki, 2010).
In short, some responses indicated that the long-term companionship and security of the garment gave the participants a sense of familiarity, making it easier for them to form habits that would lead to active using behaviour.

*Emotion transference*

The interviews also revealed that some participants' attachment to their garments came from another emotional relationship with other people or objects. For example, P1 said she bought the dress at an early stage when she was first dating her boyfriend. Accordingly, her boyfriend was considered to have an emotional connection with the dress. The precious memories and feelings naturally transferred to this dress. P3 mentioned that she was a big fan of the brand for the jeans she chose, and the feeling of trust also transferred to the product as a positive EA. It is noteworthy that every participant's experience related to their garments is unique. Thus, unlike the attachment that expresses one's personality mentioned above, the emotion that transfers from interpersonal or people-object relationships to the current AWG is more irreplaceable. This idea echoed the view from previous research, mentioning that the attachment to each garment is independent and irreplaceable due to the unique experience (Schifferstein and Zwartkruis-Pelgrim, 2008; Neto and Ferreira, 2020).

*Expectation*

Some participants' responses implied a contrast between expectations before acquiring the product and actual usage. It allowed EA to build in the initial use stage if the result met people's anticipation. P1, P4, and P6 bought their AWGs online, and the images of the products made them look forward to wearing the garments. Luckily, their high expectations were met by the results. Similarly, P3 shared her story of buying jeans in the wrong size, which was the only shortcoming of the product. She was sure that if 'I changed to a larger size they would fit me perfectly', which was true.

Conversely, there were examples of participants who initially approached the garments with low expectations. The jacket described by P5 was bought in an emergency when the weather was too cold during her trip. She bought it for the functional reason and therefore did not have high expectations of future use. However, she was surprised to notice that the jacket fit her surprisingly well, which gave her great satisfaction.

*Subjectivity*

In addition to the four themes that revealed how EA led to participants' active wearing behaviour, their stories also indicated another important prerequisite, namely consumers' subjectivity. To be more specific, EA described above would not have led to effective active wearing behaviours if participants were not making their own choices. For instance, P1 compared the dress she chose with another one sent by her boyfriend as a gift, which she seldom wore. Although both items were related closely with her boyfriend, her choice was the decisive factor for active wear. P2 said the design and structure of the skirt were 'in line with her personal aesthetics', on the basis of which she believed the product would help her display a certain personality.

Two participants further emphasised the difficulties of replacing the AWGs with other products, which reflected the subtle effect of subjective feelings. Their comments were in accordance with the idea in another related research that even physically identical replicas are not able to form exact the same attachment (Fleetwood-Smith, Hefferon and Mair, 2019). As mentioned previously, substitutes played a similar role when expressing identity, whereas memories and familiarity generated during the usage of the original product were irreplaceable.

As a representative product in the wardrobe, AWG helped shed light on the lifespan extension of all types of clothing products. The impacts of AWG on participants' general clothing consumption behaviour can also be perceived in some of their accounts, which reflected their subjective agency. Specifically, participants indicated that the existence of AWG would make their purchasing behaviours more targeted. For example, some participants prefer to buy garments with similar characteristics as AWG (P1, P5), some chose not to buy the same ones to avoid duplication (P2, P7), and one would purposefully look for specific items to match their AWGs (P4). The existence of AWG and participants' active wearing behaviours potentially help reduce unnecessary purchases in the future as consumers buy purposively rather than blindly following a trend.

## Conclusions

According to the stories from eight participants about the garments they actively wear, this study categorised EA with clothing products into four themes, including **personality**, **familiarity**, **emotion transference** and **expectation**. The findings indicated that EA to garments was established from different perspectives in various ways, which led to consumers' active wearing behaviours towards apparel products during the use phase. In addition, consumer **subjectivity** needs to be considered as a prerequisite for active use of the garments in the wardrobe and for further purchasing behaviour.

This study began by exploring how consumers explained their relationship with AWG from their perspective while uncovering the role played by EA during the use stage. Participants' phrasing, storytelling and rhetorical descriptions implied EA to the products, which were ultimately reflected in their active wearing behaviours during the use phase. As a preliminary study, it highlighted a new consumer perspective on **how** EA helped people to actively wear the clothes in their wardrobe, which was perceived through their narrative process.

Participants in this study described products they actively wear which have a relatively longer lifespan than other products in their wardrobe due to various factors of EA. This study thus contributes to the research of lifespan extension of apparel products, and in particular to the extremely shortened lifespan of garments in the current fashion industry.

The current study is part of a PhD research, and the next step will continue to explore whether different positive consumption behaviours after purchase can strengthen EA conversely.

# 3D Fashion Design Software as a Critical Design Tool for the Remanufacture of Sportswear

**Sophie Wetherell[a], Tim Nicholson[b], Alana James[c]**
a) Northumbria University, Newcastle upon Tyne, United Kingdom
b) Northumbria University, Newcastle upon Tyne, United Kingdom
c) Northumbria University, Newcastle upon Tyne, United Kingdom

**Keywords**: Garment remanufacture; 3D fashion design software; Sustainable sportswear.

**Abstract**: Sportswear as a fashion market is growing exponentially, reflecting behavioral changes in society and the development of new, hybrid market segmentations such as athleisure. Most garments within these product categories are made primarily from synthetic fibers or fiber blends, creating a problem at the end-of-life and preventing recycling or closed-loop lifecycles. To overcome challenges of multi-fibre materiality and complex garment construction, this research aimed to explore remanufacture through deconstruction and reconstruction processes using creative interplay between digital and physical development.

Across multiple sectors of the fashion industry, 3D garment design software is being extensively explored within the product development phase, however this research explores the opportunities of integrating computer aided design (CAD) software at the garment end-of-life, specifically to encourage redesign and remanufacturing. This research utilised Clo-3D to enable the reconstruction of multiple garment components (i.e. cuffs, collars, sleeves), opposed to individual panel pieces (i.e. front and back bodice) more traditionally used when manually reconstructing fashion products.

Primary experiments have confirmed the efficacy of utilising 3D fashion design software within the redesign and reconstruction of garments, allowing rapid creative experimentation and avoiding the creation of waste through trimming and extensive deconstruction. Additionally, it was found that full deconstruction of garments (to facilitate reconstruction) was not necessary, and that the use of CAD facilitated a greater level of creativity in the re-design process, with experimentation being quick and versatile in the jigsaw of garment components within a virtual space. Scalability and feasibility of mass adoption within the fashion industry will be the focus of future research.

## Introduction

Fashion as a creative practice has historically been associated with values of craftmanship and the appreciation of materiality. The *make* process relies on human tactility and as with most creative production methods, depends on learning-through-doing methodologies. Working in opposition is a significant shift towards the greater reliance on digital technologies and automated making processes evidenced across many consumer goods markets. The nature of the garment construction, however, means that digitization is impossible, with light fabrics and intricate details requiring careful precision and human agility. Consequently, fashion remains one of the only industries to maintain the hands-on craftmanship techniques during the production process, although from a design perspective, digital technologies are being embraced, and even favored to push the boundaries of seemingly limitless creativity.

In addition to the emergence of digital capabilities, the urgency of the climate crisis is forcing the fashion industry to adapt practices, moving away from the cradle to grave model of production and consumption, towards a slower, more considered approach. Common responses towards a call for sustainability have looked to material choices, moving away from an unhealthy reliance on synthetic fibers, while a call for slow fashion has played to fashion's intrinsic relationship to craft and the appreciation of heritage methodologies. Furthermore, principals of circularity are being explored within a fashion context, with both biological and technical loop principals being investigated to help retain value within the existing fashion system for as long as possible.

This research embraces these influential change factors and aims to utilize innovative emerging technologies as a vehicle to explore reuse and recycling methods with garments when they reach the end of their usable of desirable life. Adopting creative design tools, this paper questions the use of 3D fashion design software to enhance the remanufacture of sportswear garments using creative interplay between the physical and digital mediums. It furthers knowledge previously generated by the researchers, as developed through a series of staged investigations where methods of garment disassembly and reassembly have been explored. This paper takes this investigation to the next step, using conjoined garment components (i.e. cuffs, collars, sleeves), opposed to singular garment components (i.e. front and back bodice), exploring how this advanced approach could help reduce time and eliminate waste created in the process.

## Contextual Review

In 2018, luxury British brand Burberry came under intense criticism for incinerating excess stock with the value of £28.6 million, with a further £26.9 million of goods destroyed the previous year evidencing that no solutions or preventative strategies had been implemented (Environmental Select Committee, 2019). The value of these products was discarded rather than being preserved to protect the integrity of the brand reputation at a great environmental cost. This excess clothing is not however limited to industry errors but is also mirrored in the unworn clothing in consumer wardrobes, with an estimated 1.6 billion items remaining in ownership but going unworn (WRAP, 2022). This imbalance of clothing across both industry and consumer markets provides a compelling argument for principals of reuse, recycle and remanufacture being vital to retain value within the existing fashion value chain in preference to utilizing further resource in the production of new products.

Considering the environmental impact of the fashion value chain, the greatest damage occurs when the product comes to the end of its usable or desirable life, meaning that developing techniques for end-of-life management by means of product/material recovery are extremely crucial (Gungor and Gupta, 1999). Possibilities of remanufacturing has been previously explored from a fashion perspective but is more extensively explored in electronics and automotive industries. Its feasibility has also been brought into question, with the benefits of resource preservation being compared with the increase in labor intensity required to enable the remanufacturing process (Grubbstrom and Tang, 2006). This is also discussed by Stahel (2019) who acknowledges the age of a product dictating the amount of time needed, meaning that remanufacture can be a very labor-intensive process. Although it is also detailed how labor is a renewable source and can be used to bring benefits to the environment positivity of a product. This barrier to engagement with principals of remanufacture are being overcome with the potential exploration of digital technologies and automation of certain process. The development of 3D fashion design could help streamline this process, reducing the labor requirements and increasing creative possibilities.

It is anticipated that fashion brands are going to increase their reliance on technology going forward, with investments anticipated to increase from 1.6-1.8% of sales in 2021 to between 3-3.5% in 2030 (Business of Fashion, 2022). This is increasingly being evidenced by the luxury market sector, with brands such as Prada and Thom Browne collaborating with tech company Meta to enable the customisation of avatars across digital platforms through the purchase of digital pixel clothing (Parkes, 2022). The increasing relationship between fashion and the Metaverse is being reflected in the development of 3D fashion design software for the development of digital design tools in both industrial and educational applications. Developments in technology are beginning to blur the space between the physical and digital, pushing creative boundaries and encouraging brands to adapt their value chains. The increase of digital garment design, at scale, has to date been for solely the creation of Metaverse avatars, however harnessing the application of fashion design software such as Clo3D or Browzwear can adopt 2D digital behaviours for 3D creation of garments in fashion retail. The digitisation of the design and development process could ease communication with brand's supplier base, increasing accuracy, speed and reduction of waste created through extensive sampling.

Advancements in technology and changing ecological priorities are fundamentally affecting the role of the designer, with additional considerations being increasingly incorporated to their design parameters. It is widely recognized that smart solutions fit for a *new* fashion system are urgently needed, where resources can be utilized over and over again. However this shift in practice, from the use of virgin materials to the incorporation of existing materials from waste streams, does result in the role and skillset of the designer changing (Global Fashion Agenda, 2020).

From a sustainability perspective, it is acknowledged that the environmental and social impact of a product is not traditionally within the remit of the designer (Stahel, 2010), with concerns being raised about the difficulties of inclusion of such considerations in addition to their focus on more traditional design elements (Karell and Niinimaki, 2020). It is however acknowledged that it is essential for designers to attain a deep knowledge of the products they design, enabling them to know how a product will age, how long the parts should last for and if it is expected to be refurbished (Bakker et. al., 2014). McDonough (2009) notes how the designer's role is incredibly important when designing a product, as this is the stage in which it is possible to make choices that can allow the product to have another life. Furthermore, they emphasise how things need to be designed with recycling and reuse in mind, adopting a *design to redesign* and *design for a second life* mindset. However, it is to be acknowledged that this is not solely the responsibility of the designer but rather a joint effort needing a multi-stakeholder approach (Medkova and Fifield, 2016).

## Methodology

The creative interplay between digital and physical mediums remained the focus of the practice-based experiments undertaken within this research. Due to the trial-and-error approach required, moving between the two, an *action research* framework was utilised to facilitate a constant cycle of *plan – act – observe – reflect* (McKernan, 1996). Reflective of the physical, tacit nature of the experimentations carried out, Swann (2002) described action research to be a tried and tested model for translation into design practice. Using these iterative cycles, it enabled the researchers to be bold in their experimentation, with reflections and findings from the previous cycles informing the following direction of practice. Furthermore, the action research framework allowed the process to be explored in depth, placing the researchers at the heart of the process and creating a higher order of thinking about the situation (Swann, 2002).

In previous research carried out by the authors, three cycles of practical experimentation were undertaken, building foundational knowledge surrounding the process of new garment design being created from garments that have reached the end of their usable or desirable life. This was explored utilizing 3D fashion design software, in this case Clo-3D using singular garment components. Current research builds on these initial findings, incorporating two further cycles to explore how multiple conjoined garment components (i.e. cuffs, collars, sleeves), can be utilized to avoid damage, and potentially waste, being created during the disassembly process. This responded directly to observations made during previous cycles, where full disassembly of all garment component pieces rendered some unusable due to being small and damaged during the process. Utilizing conjoining garment components was explored to overcome this, and to also save time during the disassembly process.

Once disassembly had occurred, these physical garment components were digitized to facilitate redesigning opportunities with multiple component pieces, enabling creative experimentation in Clo-3D. The digitization process occurred in a number of stages to facilitate an in-depth and rigorous investigation, concentrating on quality and accuracy of the digitization process. Primarily, the garment component was mapped onto the pattern cutting paper, allowing for physical measurements to be taken (figure 1). This paper-based approach was then transferred to Adobe Illustrator and finally modelled in the Clo-3D software (figure 2). While a range of digital tools are available to enable a much quicker digitization process, the researchers chose to undertake this through the steps described to engage in a learning-through-doing methodology.

**Figure 1. Translation of component mapping between physical and digital mediums.**

**Figure 2. 3D digital modeling in Clo-3D.**

Once conjoined component pieces were digitized the digital design experimentation could begin, with several iterations and methods explored within the Clo-3D software, with a greater number of design opportunities becoming available as the component library grew. Different component combinations were explored, bringing together a number of different garments into one final design. The reshaping and trimming of pieces was also explored to facilitate a greater level of compatibility. Furthermore, the creation and new component pieces, cut from others also facilitated more breadth of creative design possibilities. Reflections were made and recorded throughout this process, from the garment component selection, the digitization of the joined components, through to redesigning experimentation utilizing digital Clo-3D tools.

## Findings and Reflections

Findings from these practical experimentations were documented by the researchers through a series of reflections on the process, drawing on their existing knowledge of garment construction and digital capabilities. In accordance with the use of action research cycles, these reflections informed and directed consequential practice and facilitated a trial-and-error approach to the investigation.

### *Physical to Digital Translation*

The process of digitizing requires a thorough understanding of the component's construction, with simple components, such as sleeves, this could be achieved quickly and easily, however with more complex components more measurement data was required and was reflected in an increase in the time required. This complexity was exacerbated when conjoined components did not lay flat due to shaping and fit created in original construction, making accurate measurement and translation form physical to digital more difficult. Despite complex artefacts being time and labor intensive, this process demonstrated that digitization was possible and less deconstruction, when comparing singular component pieces with conjoined components, reduces waste and retains material integrity. While this research utilized traditional tools and methods, future research will trial other technologies such as smart-paper and 3D scanning to see if the process can be streamlined.

Further reflection encouraged the researchers to question if this idea could be streamlined by working with garments that were originally designed using 3D fashion design software, as this process is becoming more common with the fashion industry. Having the final 3D design of a garment would allow changes to be made effortlessly and could greatly decrease the time taken to edit and adjust the remaining garment components according to condition and/or desirability. This idea began to position the research in a more commercial space and will be explored in collaboration with an industry partner in future research.

### *Digital Redesign Opportunities*

Once a number of garment components had been digitized to create a library, the design possibilities could start to be explored. The 3D fashion design software facilitated this process with ease and made experimentation of moving component pieces simple. This process of adapting existing 3D garments worked very well, and it is simple to do once the process is practiced.

Overlaying of pieces to trim and ensure fit was also facilitated easily, and although this process created small quantities of waste, it did allow much large piece to be reused and replaced.
This is only possible however if the new piece is either the same size or larger at the point of the

joining seam, otherwise an additional pattern piece needs to be added. To check pattern pieces are large enough is a very simple process over overlaying the two components.

**Figure 3. Digitally redesigning with multiple garment components.**

The example shown in figure 3 demonstrated how joined components can be easily placed into this system as the cuffs of the sleeves followed along with no extra effort from the user. More complex garment combinations could be completed using this technique, but a deeper knowledge of the software is needed to ensure it is done accurately enough to be able to transfer the data into a new physical outcome.

## Conclusions

This paper built on the authors previous findings which highlighted that 3D fashion design software can act as an effective tool to aid, and encourage, designers in constructing new products from existing garments. This paper developed this experimentation further, moving from working with individual garments components to exploring the redesign opportunities when working with conjoined garment components. This approach directly targeted issues regarding the creation of waste, time intensive deconstruction and complexity of redesign methods. Although this approach raised challenges regarding accuracy, measurement and fit, the authors proved that the integration of Clo-3D to enable this process worked effectively. The research however highlighted the depth of knowledge and experience needed to work with existing garments for reconstruction purposes, with additional proficiency in specific software applications were also paramount. When comparing the physical and digital process, it was found that the use of 3D fashion design software significantly increased creativity and facilitated a breadth of experimentation easily. The possibilities of outcomes were also greatly increased with the number of components available, meaning that the creation of a library or depository of digitised pieces was beneficial.

The fashion industry is evidencing a shift towards embracing digital capabilities and is increasingly feeling the pressure to work within planetary boundaries. Utilising 3D fashion design software at the back end of the value chain can facilitate remanufacture and help retain material value within an existing system. While traditionally utilised during the primary design phase, this on-going research demonstrates that addressing excess quantities of clothing already in existence can begin to work towards sustainable solutions by encompassing new digital innovations, reflecting the direction of change within the wider fashion context.

# New Metaphors for Plastic Packaging

**Garrath T. Wilson[a], Harriet M. Baird[b], Rorie Beswick-Parsons[b], Nikki Clark[a], Saima Eman[b], Joanna Gavins[b], Sarah Greenwood[b], Debra Lilley[a], Paul Mattinson[b], Thomas L. Webb[b], Elliot Woolley[a], Princess Woy[a], Nicola York[a]**
a) Loughborough University, Loughborough, UK
b) The University of Sheffield, Sheffield, UK

**Keywords**: Packaging; Design; Plastic; Metaphors; Circular Economy.

**Abstract**: Packaging is typically viewed as a product delivery system to be discarded having fulfilled this function, thereby wasting the resources and potentially causing further harm. Changing this situation will likely involve new technologies, systems, and approaches, but will also require people to rethink their relationship with packaging, potentially in radical ways that embrace, rather than reject, the signs of previous use that are likely to accrue in more circular systems. The present research used an interactive online workshop to envisage potential metaphors for human's relationship with packaging and to consider how these might shift thinking and behaviour. In total, 16 new metaphors for people's relationship with plastic packaging were generated during the workshop, including "I may have let myself go but you still love me" (the idea that continued use despite wear signals commitment), "lost and found" (the idea that one person's loss is another's gain), and "being a parent to packaging" (the idea that people have a responsibility to care for packaging). Activities might now be designed to disseminate these new metaphors. For example, we have established '(Pack)age Concern' with the goal of "calling out cruelty to plastic packaging and helping them live a long and happy life".

## Introduction

The science is unequivocal; we are living in a new geological epoch, a manufactured by-product of the abusive relationship of human to planet, the Anthropocene (Lewis & Maslin, 2015; Steffen et al., 2011). Several planetary boundaries have been exceeded (IPCC, 2001; Persson et al., 2022; Steffen et al., 2015; Walther et al., 2002), perpetuated in part by the 'take-make-dispose' economies of the Global North. In this context, plastic packaging is often made from virgin and/or recycled material, it performs several functions, including but not limited to protection, preservation and distribution of product (Parsons, 2022), and is disposed of once its role is complete; the majority of its value lost (Ellen MacArthur Foundation, 2016). This is especially a concern when considering, for example, the size of the UK Food to Go industry. The environmental charity Hubbub claim that 10.7 billion items of food to go waste is generated annually (Smithers, 2019) with the majority of that plastic not being kept within the system.

Whilst attempts at amelioration do typically try to move away from single-use product delivery systems towards reuse models (for example, TerraCycle's 'Loop' service, or the projects supported by the Hubbub and Starbuck's 'Bring it Back Fund'), efforts are currently small-scale and/or focused on particular product categories and utility, so therefore do not achieve either the scale or breadth required to fundamentally address the challenges. We argue that the scale of change required to reduce plastic waste and move towards a more circular economy cannot be made manifest within these limited conceptions and trajectories.

To question this status quo in a meaningful way, we propose that the 'system border' needs to be expanded to consider positions that are atypical to current definitions of problem and solution within the packaging industry (Dorst, 2015). Metaphors are increasingly becoming one way in which product and service designers are creatively exploring the 'bounding' of both problem and solution spaces, or creating new frames entirely (Lockton et al., 2019; Wilson et al., 2022). We therefore collaborated on a 'New Plastic Packaging Metaphors' workshop that sought to envisage new – potentially radical – ways of thinking about our relationship with plastic packaging. In this workshop we considered the consequences that these novel ways of viewing the interaction between humans, packaging, and planet might have for use, reuse, and end of life as we attempt to transcend towards the Circular Economy.

## The Workshop

Using and reusing packaging and containers multiple times confers environmental benefits but use typically leads to signs of wear (e.g., scratches from cutlery, stains from repeated exposure to food, or scuffing from contact on filling and packaging lines) which people can interpret as a sign of contamination (White et al., 2016). However, could packaging damage and material change, such as a scratch or a scuff, signal other types of information, perhaps even replace consumables like physical labels – in a sense, a low-carbon form of 'alternative labelling'? This provocation inspired an interdisciplinary workshop in a first attempt towards generating the required new alternative frames for human relations with plastic packaging.

Utilising the 'New Metaphors' creative toolkit (Lockton et al., 2019) as the basis, a 3-hour workshop facilitated by Miro (an online professional diagram collaboration software) (Figure 1) in February 2022 drew together ten academics from a range of disciplines (including Design, Sustainable Manufacturing, Human Geography, Psychology, and English Language and Literature) with knowledge of smart sustainable plastic packaging (see: Bradley et al., 2023; Clark et al., 2020; Greenwood et al., 2021; Nahar et al., 2022; UKRI, 2020; Wilson et al., 2022; Woy et al., 2023).

The workshop initially introduced the theoretical concept of metaphors and their relevance to design practice. For the purpose of the workshop, we used the broad working definition: "Thing A is perceived to have features like Thing B", in which relatable everyday familiar terms and notions ('concepts' and 'images') are used to explain and define more abstract ideas and features. Consider, for example, that a product cannot actually have a 'life cycle' as it is not alive, but it is a useful conceptual framing device in which to position reduce, reuse, recycle etc. Next, participants engaged in a creative immersion activity in which 'concepts' were combined with 'images' to create new metaphors, to get the participants from a range of backgrounds thinking metaphorically. The final activity was designed to facilitate the creation and exploration of new metaphors for human relationship with plastic packaging within 'Artefact Centred' (from the perspective of the packaging itself), 'Citizen Centred' (thinking about the human role centred within the packaging 'use' system), and 'Planet Centred' (an overarching environment-first approach) lenses. Having multiple lenses encourages participants to think beyond what their typical domain perspective may be (a user centred designer may think citizen-centric by epistemology for example). Participants were invited to select an image (e.g., of cracks in paving, a rollercoaster, a windsock, or bubbles) and a concept (e.g., symbiosis, unwritten rules, relationships, or the future) and then to think about how they might be paired to create a new metaphor (Figure 2). For example, a relatively literal pairing of an image of bubbles with the concept of 'the future' might lead to the metaphor that each person is just one bubble in the foam of humanity.

## New Metaphors for Human Relations with Plastic Packaging

In total 16 new metaphors for people's relationship with plastic packaging were generated during the workshop. These are summarized in Appendix 1, but below we provide a few illustrative examples that we believe have potential for shifting the way that people think and behave with respect to packaging.

Metaphor 3, framed colloquially as "I may have let myself go but you still love me", combined the concept of 'Love' and the image of 'Erosion' to question whether embracing the degradation of packaging over time could be viewed as the unconditional commitment of the human to that object. As the metaphor suggests, there may be an opportunity for emotionally durable relations, supported with new packaging materials or manufacturing processes, that better enable and reflect unconditional long-term commitment. One such direction may be greater consideration of the 'Interaction of Material Change and Material Experience' framework (Lilley & Bridgens, 2021) within the design process. Could this framework be leveraged to modify cerebral and behavioural responses towards changes in physical care and maintenance, ultimately affecting future product life?

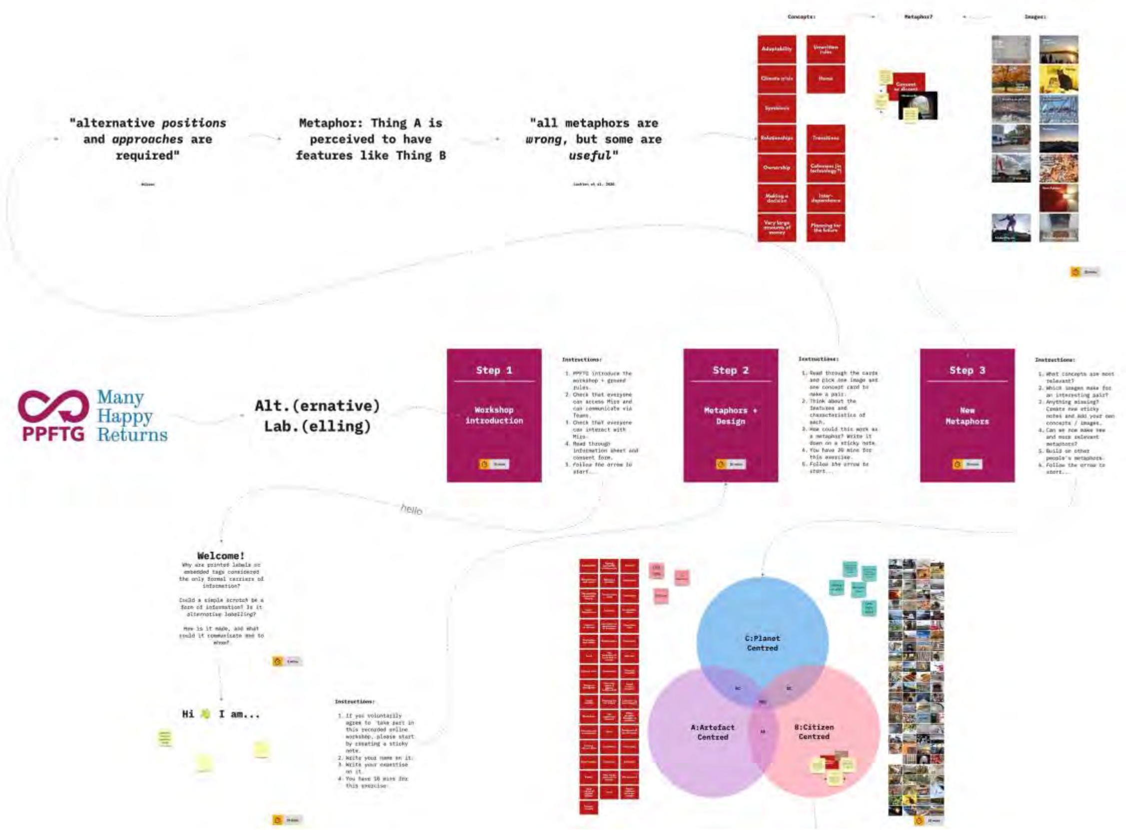

**Figure 1. New Plastic Packaging Metaphors Workshop Overview.**

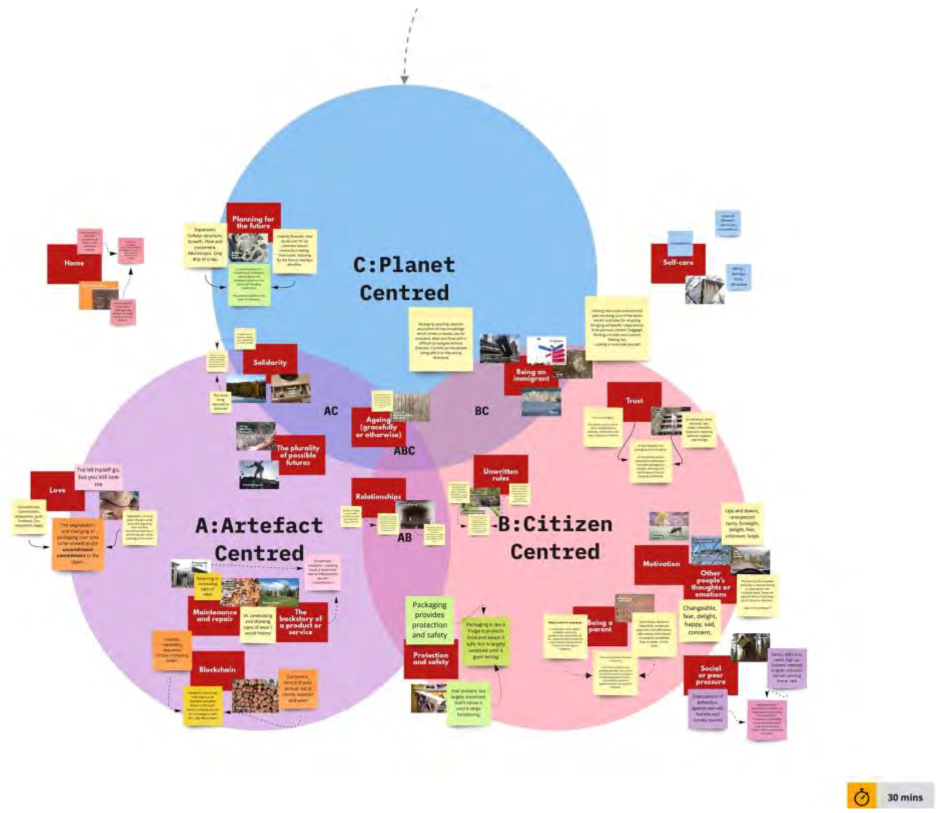

**Figure 1. The Generation of New Metaphors.**

Metaphor 7 took the concept of ‘Relationships’ and the image of ‘Lost and Found’ to explore the idea of right to ownership, and that the neglect of an artefact (e.g., package or container) will result in both its loss of partnership and servitude, but also could lead to someone else to discover its value and to gain a new relationship. Could this metaphor indicate a pathway towards new reuse and recycling models? The typical business models of service that involve packaging – linear or circular – are predicated on economic value and transaction, but could that value be transformed (den Ouden, 2012)? Could economic value be turned towards or into something more meaningful and responsible, something more human and nurturing, towards benevolence, stewardship, or compassion? Conversely, is there something to learn here about the dwindling of relationships and the managed separation that comes with formal partnership dissolvement? Or the chaotic separation that comes with telling someone they are no longer loved via text, or the management of the fall out after finding a ‘better option’ on a night out?

Metaphor 14 explored the combination of the concept ‘Being a Parent’ with the image ‘Patterns in Brickwork’. Here, we started to question whether it’s OK to be a bad ‘packaging parent’ if the ‘packaging baby’ survives. Framed within the workshop as the ‘National Society for the Prevention of Cruelty to Plastic’, this was subsequently iterated post-workshop to ‘(Pack)age Concern’ with the goal of “calling out

**Figure 2. A typical (Pack)age Concern Social Media Post (Twitter).**

cruelty to plastic packaging and helping them live a long and happy life”; in essence, what services may need to be provided to prevent ‘packaging cruelty’? To explore (Pack)age Concern further we started to seed the concept into the real world, from the abstract back into the concrete. One method was to establish a social media presence for the imagined charity (Figure 3). Taken further, one might start exploring how to establish such a charity for real with the intent of lobbying for policy change and providing help for ‘packaging carers’.

## Conclusions

Taken together, this interdisciplinary workshop functioned as a useful means of collaborative creative ideation with respect to how people might rethink their relationship with packaging – something that we believe is vital for enabling the transition towards a Circular Economy. Purposefully exploring alternative frames and concepts without the shackles of technical and marketing requirements allows new directions to be identified which can then be probed, interrogated, and reflected upon. We are not proposing that the metaphors we have generated are the ‘right’ solutions, but they are a flag in a much broader space of possibility rarely considered and never acted upon. They are a starting point for vital conversation to expand the possibilities, thereby ultimately finding new and viable directions towards enhanced sustainability goals. However, for this endeavour to contribute towards the larger objective of reducing the negative environmental impact of packaging, new ways of thinking will need to be disseminated and adopted, including within industry; who will also need be willing to deviate from viewing plastic packaging as simply a single-use product delivery system.

## Appendix 1 – New Metaphors

| | Concept | + | Image | = | New Metaphor Notes |
|---|---|---|---|---|---|
| 1 | *Planning for the future*<br><br>Expansion. Cellular structure. Growth. Flow and movement. Microscopic. Drip drip of a tap. | + | *Bubbles, foam, or droplets*<br><br>Looking forwards. How do we plan for an unknown future? Instinct/Gut feeling. Time travel. Visioning for the future. Having a direction. | = | Visualising an individual's part to play in the planetary system or the system of recycling. Collectivism. You are one bubble in the foam of humanity. |
| 2 | *Home*<br><br>Safe, sanctuary, a place for something, an origin, where something belongs. | + | *Facial expressions*<br><br>Communication, involuntary, faked, genuine, present an image to the world, joy, emotions. | = | The home of packaging? Is packaging homeless? Packaging is a vector so does it belong anywhere (like electricity?) |
| 3 | *Love*<br><br>Unconditional, commitment, uniqueness, quirk, fondness, fun, enjoyment, happy. | + | *Erosion*<br><br>Degradation, wearing down, change, eating away, disintegrating, wear and tear, something enacting on something else, decay, markings of the action. | = | The degradation and changing of packaging over time to be viewed as the unconditional commitment to the object. |
| 4 | *Blockchain*<br><br>Indelible traceability, sequential, unique, increasing ledger. | + | *Tree rings*<br><br>Concentric, record of past, annual, old at centre, weather and wear. | = | Metaphor history log: tree rings are an indelible, traceable record of the past - there is nothing we can do to change or alter this - like Blockchains. |
| 5 | *Maintenance and repair*<br>and<br>*The backstory of a product or service*<br>Celebrating and showing signs of wear / social history. | + | *A temporary covering*<br>and<br>*Traces of previous messages*<br>and<br>*Traces of use*<br>Reversing or concealing signs of wear. | = | Problematic metaphor. Cleaning is just a temporary way to hide previous use and contamination. |
| 6 | *Ageing (gracefully or otherwise)* | + | *Traces of how something was made* | = | We see age as the traces of the past and the way in which we've grown. Our views of ageing are like the rings of a tree - clear to see if you open us up (and talk to us). The same is true for our planet, the way we treat it shows its age, no longer the pristine Gaia it was. |
| 7 | *Relationships*<br><br>Symbiosis, relying on each other, quid pro quo, you give I get, love, care, to think of. | + | *Lost and found*<br><br>Something is gone, you have lost the use of something, carelessness, no longer have access, to find, to gain something new (or old). | = | A struggle to maintain and care for an artefact that if we don't care for will result in loss due to carelessness. This loss could lead to another person finding it? |
| 8 | *Protection and safety*<br><br>Packaging provides protection and safety. | + | *The hum of a fridge*<br><br>Ever present, but largely unnoticed. Don't notice it until it stops functioning. | = | Packaging is like a fridge it protects food and keeps it safe but is largely unnoticed until it goes wrong. |

| | | | | | |
|---|---|---|---|---|---|
| 9 | *Unwritten rules*<br><br>Rules not everyone knows, confusion, exclusive, you're not cool, you can't sit with us, social expectations, cultures, to follow. | + | *A walled garden*<br><br>Thou shall not pass, beautiful on one side, wondering what's on the other side, flowers, a gate, something keeping you out. | = | You have to know the rules to be able to play the packaging game - no one really knows where to recycle things or when, this keeps people out of sustainability - they can't join the new age cool kids' sustainability club. |
| 10 | *Self-care*<br><br>Convenience. | + | *Rust*<br>Decay, entropy, time, attractive. | = | Trade-off between time and inconvenience. |
| 11 | *Being an immigrant* | + | *A bridge that opens*<br><br>and<br><br>*A signpost*<br><br>and<br><br>*A net*<br><br>and<br><br>*Waves* | = | Packaging recycling requires acquisition of new knowledge which comes in waves, can be turbulent, ebbs and flows and is difficult to navigate without direction. Current carries people along with it (in the wrong direction).<br><br>and<br><br>Coming into a new environment and not being sure of the social norms and rules for recycling. Bringing old beliefs / experiences from previous context 'baggage'. Finding a hostile environment Feeling lost. Looking to orientate yourself. |
| 12 | *Trust*<br><br>Trust in packaging: firm belief, trust in self or others (stakeholders), reliability, relationship, two-way, integrity, confidence. | + | *Steps*<br><br>Incremental, climb, descend, over, under, transition, internal or external, balance, support, step change. | = | A new metaphor for packaging reuse integrity: Incrementally we can transition to believing in reusable packaging as reliable, allowing us to climb above mistrust, building confidence. |
| 13 | *Motivation*<br><br>and<br><br>*Other people's thoughts or emotions*<br><br>Changeable, fear, delight, happy, sad, concern. | + | *Grazing*<br><br>and<br><br>*A rollercoaster*<br><br>and<br><br>*The road ahead*<br><br>Ups and downs, unexpected turns, foresight, delight, fear, unknown, loops. | = | The journey of a reusable container is represented by a rollercoaster with multiple loops. There are signs of where it has been, but its future is unknown. Fear of the unknown? |
| 14 | *Being a parent*<br><br>Being a parent to packaging: looking after, care, neglect, adoption, ownership, guardianship, stewardship, for life...whose life? Who makes the rules? National Society for the Prevention of Cruelty to Packaging. | + | *Patterns in brickwork*<br><br>Same shape, structure, repeatable, consensus, alignment, but differences, adds texture and interest, on purpose, accidental, does it matter, is it for show. | = | The new metaphor for reuse consensus? 'Don't tell me how to be a packaging parent'. Some of us can be bad parents, as long as the packaging baby survives... Bounded by a universal agreement but rules up to the individual. |

| | | | | | |
|---|---|---|---|---|---|
| 15 | *Social or peer pressure*<br><br>Expectations of behaviour, against own will, fashion and trends, routine. | | *Birdboxes*<br><br>Safety, difficult to reach, high up, isolated, unwisely brightly coloured, narrow opening, home, nest. | | Misjudged norms:<br>Sometimes our habits and expectations of packaging are unwanted or unnecessary. Big brightly coloured birdboxes that look like Hansel and Gretel's' (witch's) house are not useful. |
| 16 | *Solidarity*<br><br>Together we are stronger, support, unity, agreement, common interest. | | *Reflections*<br><br>and<br><br>*Fitting things around each other*<br><br>The same thing repeated or distorted. | | Together they stand, the artefact a distorted reflection of what the planet has built. They are united (sustainable packaging) with nature. |

# Identifying Opportunities to Increase Food-To-Go Packaging Lifetimes Based on the Current Conceptualisation of Food-To-Go

**Princess Woy[(a)], Garrath T. Wilson[(a)], Stuart Cockbill[(a)]**
a) Loughborough University, Loughborough, United Kingdom

**Keywords**: Sociocultural Behaviours; Food-To-Go; Convenience Food; Regenerative Behaviour.

**Abstract**: A substantial contributor to adverse environmental effects is the £18.9bn UK food-to-go (FTG) market. There is a clear need for more regenerative and pro-environmental behaviours within food systems. Lifetime extension is a strategy within a circular economy which enables keeping products in use for longer. To extend FTG packaging's life, part of the dialogue required is understanding why and how limited FTG packaging lifetimes occur through disentangling current social behaviours around FTG retailing and consumption. A content analysis of literature from the global market intelligence agency 'Mintel' was conducted, identifying two key opportunities to encourage regenerative behaviour in FTG: (1) viewing FTG as an established industry ripe for disruption; and (2) focusing on the experience of FTG as a meal format. Barriers to regenerative behaviour were also identified including FTG's transient nature making it hard for companies to have control over consumers' use of the product; the extensive 'convenience culture' (CC) paradigm that permeates much of Britain's consumption behaviours; and the connection between impulse purchases and FTG products.

## Introduction

Current food production and consumption methods have significant adverse outcomes, impacting both economy and environment (Baker et al., 2020; Thomas et al., 2019). The UK food-to-go (FTG) market is a substantial contributor, valued at £18.9bn in 2022 (IGD, 2022). However, whilst FTG is an established term within industrial contexts it has not been well-defined in academic literature (Clark et al., 2020; Drexler et al., 2017; Heider & Moeller, 2012). A typical simplified definition is that FTG consists primarily of pre-packaged portable items eaten out of the home, such as sandwiches and salads (Clark, 2021; Drexler et al., 2017).

The FTG industry has sustainability issues, primarily its reliance on single-use packaging. Packaging plays an essential role in preserving FTG items to prevent food waste, but also contributes to the system's linearity and therefore its unsustainability. Given the scale and urgency of these issues, there is a clear need for change within FTG. Businesses concerned with FTG are aware of this need and have begun partnering with institutions and research centres to innovate and decrease environmental impacts (Greenwood et al., 2021; UKRI, 2020b, 2020a; Wilson et al., 2022) However, many of these projects follow a similar trend of doing 'more-with-less' in terms of material resources and don't question how FTG is currently conceptualised. Conversely, this paper aims to identify where a new, more sustainable, and regenerative behaviour could grow in the industry's current conceptualisation of FTG.

## Current Conceptualisations of Food-To-Go

Convenience foods have been discussed in academic literature since the late 20th century. As convenience uptake increased, scholars have attempted to define convenience foods in home and commercial settings (Traub & Odland, 1979). FTG, however, remains unexplored from a behavioural angle; there is little published research exploring the purpose of FTG and its place in British culture. Studying sociocultural behaviours through the lens of written discourse has shown to be a robust scientific method (Kelly, 1998; Makri & Kynigos, 2007). This paper follows a similar approach by analysing text reports produced for the FTG industry. A content analysis of literature from the global market intelligence agency 'Mintel' was conducted to identify where a new and more sustainable and regenerative idea of FTG could sit in the industry's current conceptualisation of FTG.

An inductive content analysis was undertaken, searches were conducted on the Mintel Academic website between the 7th and 11th of March 2022, using the terms "Food-to-go" and "on-the-go", in addition to phrases found on Mintel and synonymous with FTG ("on-the-move" and "Grab-and-Go"). Mintel was chosen as a trusted industry-based source because it is a global market intelligence agency that produces reports for Industry. They have several FTG-related reports looking at consumer behaviour and the FTG market. Only reports focused on the UK were included as the term FTG appears primarily in British corpus (Clark et al., 2020; Hirth et al., 2021). Paragraphs were selected using the following criteria:

- The paragraph mentions one of the following phrases: "Food-to-go", "on-the-go", "on the move", or "Grab and Go".
- A report published between 2021-2022
- A report focused on the UK.

Data collection resulted in paragraphs from 28 separate Mintel Reports. NVivo software (QSR International Pty Ltd, 2018) was used to analyse all paragraphs captured. Paragraphs were coded to a key phrase node, denoting the search phrase to which it was related. Categories were produced by theming related phrases and determining sub-themes where appropriate. The results were abstracted into a written understanding of FTG's conceptualisation and a concept map.

## Findings

Data collection and analysis resulted in five major categories.

### 1. *Typified by relation to consumer use*

1.1 Manner of Usage
This category is characterised by relating FTG to how a consumer uses it, with significant themes being 'Eating whilst moving/travelling' and the 'Takeaway Nature' of FTG. Both point to an integral part of FTG being something bought to be eaten away from the sales point, either whilst travelling or at a destination.

1.2 As an Occasion
This category is characterised by referring to FTG as a specific occasion or instance within a person's day. *"Babybel launched its first ever functional cheese snack range in February 2021, specifically targeting the food-to-go occasion."* (Mintel & Pilkington, 2021). This characterisation adds a temporal element to FTG's definition and exemplifies it as a type of meal format. Its temporality refers to FTG being a bounded event with a beginning and an end. Temporality is not the only defining criteria of a FTG occasion, it is also characterised by food attributes, food composition and the circumstances of the occasion.

1.3 As Part of Impulse Purchases
This category primarily consisted of mentions of FTG as related to impulse buying or 'hasty shopping".

### 2. *Typified by Outlet Format*

2.1 As A Way of Describing an Outlet, this category was the most referenced within "Outlet Format" (20 paragraphs); it captures all uses of FTG terms as an outlet type. It also refers to shops and retailers as 'food-to-go' outlets. The term FTG is used as a descriptor and a designation of a type of location that sells food: *"food-to-go outlets that are characterised by the takeaway nature of food and drink such as coffee shops and sandwich shops."* (Mintel & Caddy, 2021a). A level of convenience and speed of service characterises these outlets. *"Swift which promises 'Fast, Fresh, Local' produce."* (Mintel & Butel, 2021)

2.2 By Store Location
This category concerns the locations mentioned around FTG outlets and brands. Every reference within this category used the word "city", and half of the references explicitly talked about the "city centre".

2.3 By In-Store Location
FTG can be sold in FTG outlets and within non-FTG outlets, such as supermarkets and grocery stores. This category concerns the latter as there were multiple mentions of FTG being sold within "*Grab and Go*" chillers, adding to the definition of supermarket-style "Food-to-go": items typically sold near the front of the store in a refrigerated area.

2.4 By the Type of Things Sold

This category starts to differentiate FTG from the term takeaway, which typically refers to cooked meals bought at a restaurant (Cambridge Dictionary, 2022). In comparison, FTG outlets are characterised by serving pre-prepared and often pre-packaged hot or cold food. It is essential to mention, however, that references within this category all refer to outlets that sell FTG and not FTG brands like Subway, as places like Subway and Greggs do not primarily sell pre-packaged food. *"Morrisons expanded its food-to-go concept … Offering a menu of freshly made food-to-go and made-to-order options pre-packaged"* (Mintel & Pilkington, 2022). Table 1 shows the top food types in this category and the number mentions. Other typical FTG items in this category were 'baked' foods and bakery items.

| **Meal type** | **Number of Mentions** |
|---|---|
| Meal | 48 |
| Lunch | 34 |
| Sandwich | 24 |
| Snacks | 23 |
| Coffee | 16 |

**Table 1. Meal types mentioned within the 100 most frequent words in the theme 'By the type of things sold' and the number of times they were mentioned.**

## *3. As a Type of Brand*

This category serves to gather all references to brands concerning FTG. Table 2 presents all brands described as "Food-to-go" or "Grab and Go".

The brands presented relate to previous categories described, such as category 1.1 Manner of Usage, concerning consumers eating food away from the establishment where they bought them. Brands such as 'Greggs' and 'M&S Simply Food' do not always have indoor seating, so people eat purchased items off-site. Similarly, whilst outlets like Pret-a-manger and itsu do offer indoor seating, they sell their food in pre-packaged formats that are easy to take away from the store.

| ***Brand*** | ***Number of mentions*** |
|---|---|
| **Greggs** | 11 |
| **Pret a Manger** | 5 |
| **itsu** | 3 |
| **Subway** | 2 |
| **Wasabi** | 2 |
| **M&S Simply Food** | 1 |

**Table 2. Number of references coded at each brand and the term(s) used in the reference.**

## *4. A Specific Type of Offering*

FTG can be described as a specific type of food provision companies offer. It can be a specific food option that companies can include in their portfolio. Mintel uses the term FTG in this way to describe different food provisions that businesses have: *"Compass Group shifted … to grab-and-go offerings, a meal format also suitable for takeaway and delivery."* (Mintel & Caddy, 2021b). Here, they also define a FTG offering by implying that this type of meal format is easy to consume outside the store.

4.1 Relevance to The Law

When defining FTG as a provisioning type, existing legal definitions are relevant. A recent law mentioned within Mintel is "Natasha's Law", which states that all found outlets selling *Packed for Direct Sale foods* (PPDS) must provide full ingredient lists in the UK. *"PPDS is food that is prepared, prepacked, and offered or sold to consumers on the same premises."* (BSACI, 2021). Mintel then relates this definition of PPDS foods to previous outlets and brands that it has described as being FTG brands:

*"Most grab-and-go foods from the likes of itsu, Greggs and Pret a Manger would therefore fall into the scope of Natasha's Law."* (Mintel & Caddy, 2021c).

This sub-category relates to FTG as typically pre-prepared and pre-packaged (see category 2.4.).

### *5. An Industry Sector*

This category highlights the small number of references (5) to FTG as an industry sector or a potential market. The lack of references to FTG as an industry sector shows how it is not a well-defined market within existing food sectors. It instead falls under other existing areas and market descriptors such as “Lunch Out-of-Home” and “Convenience Stores”, both of which are report headlines that Mintel has used.

### *Summary*

In conclusion, when combined, these categories help form a fuller picture of the current industry conceptualisation of FTG (Figure 1).

FTG is considered a part of a convenience lifestyle, influenced by the overarching concept of “Convenience Culture” (CC). This conceptualisation further establishes FTG as a specific meal format, of which essential components are the ‘*context in which you eat your meal’* and the ‘*type of food eaten’*. The typical context includes eating whilst moving, a portable nature, and a bounded occasion. The context further contributes to FTG as an outlet descriptor. The types of food typically eaten during a FTG occasion include lunchtime meals, snacks, coffee, and sandwiches contributing to FTG as an outlet description. FTG as an outlet descriptor generally refers to outlets that sell FTG-style food offerings and are based near city centres or areas of journeying (transport hubs). Consequently, FTG, as a type of brand, is based on a business having a collection of FTG outlet formats.

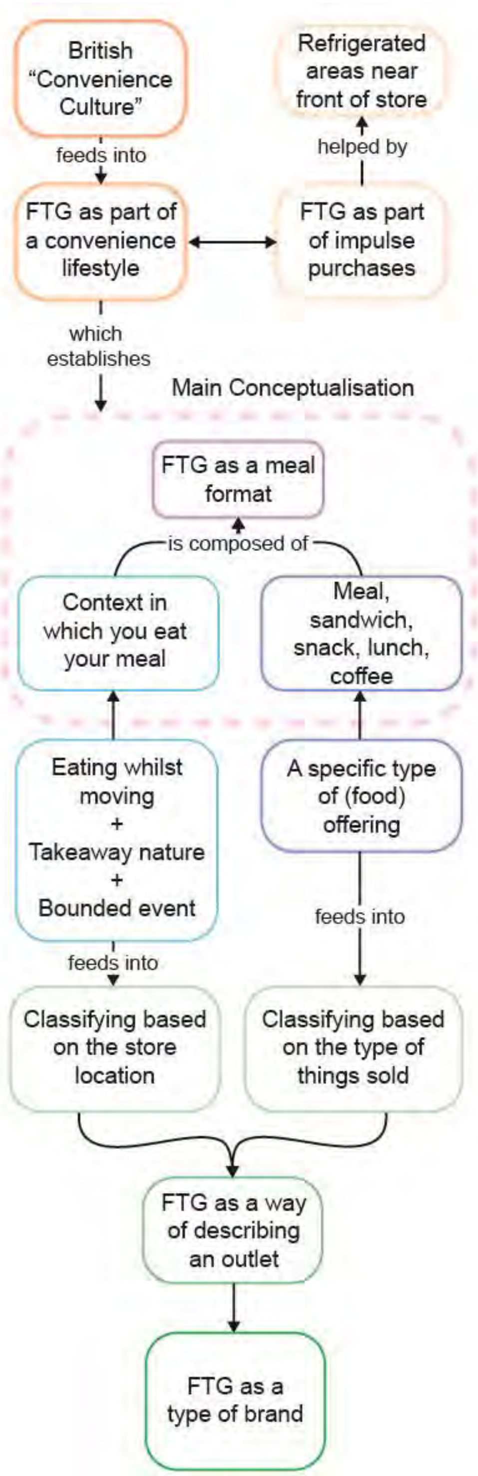

**Figure 1. Concept map of FTG based on categories defined in this paper.**

## Opportunities To Increase Food-To-Go Packaging Lifetimes

Two areas that help shape the conceptualisation of FTG were identified: (1) relationship to consumer use and (2) outlet format. In addition, three ways in which the term FTG is used were identified: (1) as a type of brand, (2) as a specific type of food offering, and (3) as an industry sector. This section discusses opportunities to increase food-to-go packaging lifetimes based on the current understanding of food-to-go as sociocultural behaviours and current barriers to this.

### *Opportunities*

FTG could experience disruption similar to other industries if regarded as a sector. Over the last 50 years, established industries have often succumbed to new processes and technologies (Christensen et al., 2015). These disruptions tend to ripple across the entire sector's landscape, such as uber, which first infiltrated the taxi industry and more recently food delivery systems, thereby contributing to the trend of the gig economy disrupting established industries. Further, by conceptualising FTG as a meal occasion type, companies could focus on the experience of FTG as a meal format and therefore create a more holistic view where pre-conceptions of FTG packaging are irrelevant. Designers have shown that there is scope for behaviour change even with products deemed to be takeaway in nature (Clark, 2021). This provides an opportunity to re-design the services that support FTG utilising Service Design (Dorst, 2011; Meroni & Sangiorgi, 2016; Nisula, 2012; Sierra-Pérez et al., 2021).

Barriers

FTG's inherently transient nature, supported by the synonyms "food-on-the-go" and "food-on-the-move", makes it difficult for companies to understand the FTG consumer experience. If people eat their FTG in other locations, companies may feel less responsible for what happens at the end of the FTG use-cycle, though there are some examples of this changing (Clark et al., 2020).

FTG being part of a "convenience lifestyle" relates to overarching sociocultural behaviours. It refers to a fundamental undercurrent of FTG's current perceptions as an integral part of British CC, leaving little to no room for change within existing FTG paradigms. If the Industry believes that FTGs current permutation is part of a broader cultural context, then there is no incentive to change and become a disruptor. This conceptualisation places the blame on the broader culture, trapping industry in the loop of designing for convenience, as companies are unconvinced that users will adopt any change; They prefer to continue the status quo of "Convenience Culture" (CC). To address this requires a mindset change and systemic adjustment within the culture of the UK. Research shows that both consumers and companies 'created' CC, so a shift is possible (Bonke, 1996; Scholliers, 2015; Warde, 1999).

Impulse purchasing of FTG is related to its conceptualisation as part of CC, affecting its marketing. FTG's packaging is designed for an economy with a make-take-use-dispose mentality. When someone purchases something impulsively, they are less likely to be attached to the product (Chen et al., 2020), and therefore less concerned about its disposal. Whilst this view does allow for some sustainable behaviour, e.g., recycling, it still relies on a convenience-first mindset. Consequently, whilst aspects of sustainability could be addressed, regenerative behaviours are unlikely to be tackled without a change in mindset.

These barriers suggest a need for a more significant mindset shift within Industry to encourage regenerative behaviours. The mindset change could start by re-focusing on a different part of FTG's conceptualisation, making the focal point the holistic experience of FTG instead of just the food, the packaging, or the convenience. This change in focus could be the enabler for more regenerative FTG systems.

## Conclusions

Food-to-go (FTG) is a social construct; multiple elements and factors make something a "food-to-go occasion" or "food-to-go outlet", but alone none of these elements operationalise the term food-to-go. This work provides the framing required to understand social behaviours related to the current conceptualisation of FTG. This paper identified two key opportunities to create a more regenerative behaviour in FTG: (1) by viewing FTG as an established industry ripe for disruption; and (2) by focusing on the experience of FTG as a meal format. However, in addition to these opportunities, several barriers were identified. These included FTG's transient nature making it hard for companies to have control over consumers' use of the product, the extensive "CC" paradigm that permeates much of Britain's behaviours, and the connection between impulse purchases and FTG products.

# Unfolding Openness: Critical reflection on the open design projects in Turkey

**Lilyana Yazirlıoğlu[a,c], Ayşe Kaplan Sarısaltık[b,c], Demet Doğanay[c]**
a) Ulster University, Belfast, United Kingdom
b) Oslo Metropolitan University, Oslo, Norway
c) Middle East Technical University, Ankara, Turkey

**Keywords**: Open design; Maker movement; Open sharing; Designer roles; DIY.

**Abstract**: In recent years, Open Source Sharing and Maker Movement have become popular and have triggered a community of people who are enthusiasts of learning, making, creating projects, and sharing these projects and knowledge with others. These movements' development and maturation can be affected by local circumstances as well as the availability of resources and infrastructures, and people's approach to openness for such processes. The question is, then, who are the individuals and communities that identify themselves with these practices, and how able are they in their endeavor of open design? Are the open processes really open to anyone and applicable everywhere? Through a critical reflection on six open design projects produced in a graduate course, the makers' characteristics and local conditions' effect on open design processes are examined as a case. Therefore, the first aim is to analyze different perspectives and degrees of openness using (Balka, Raasch & Herstatt, 2010) terms of transparency, accessibility, and replicability. Although projects fulfilled most of the aspects, they failed to achieve accessibility due to the economic and social conditions in the local setting. The secondary aim was to analyze the open processes by considering the changing roles of the researchers as project makers since the processes are highly affected by the makers' backgrounds and knowledge. The making process is experienced as if it was an amateur pastime (Von Busch, 2012) or productive leisure (Atkinson, 2011) since making flawless products was not the only and direct aim of the class.

## Open Design and Criteria of Openness

When it comes to openness, there are a variety of definitions and discussions on what openness is, its elements, and what makes a project to be an *open design project*. Pomerantz and Peek (2016) state that the term openness might imply that a resource is available to anyone for no charge, it can be adapted to any use, anyone can participate in the process, and the artifacts of the process are also accessible in any way possible.

This definition also correlates to the earliest example of open-sharing concepts, known as *Open Source, which* refers to sharing software and codes openly without any means of profit (Harhoff et al., 2003). This practice has been around since the 1970s and became widespread in the 1980s. Also, the term *Open Design* used for hardware and physical products (Vallance et al., 2001) has been spread. The first open hardware practices may be considered to coincide with the DIY (Do it yourself) movement in the heights of the 1950s and 1960s, extending its existence to this day. The transition from industrialism to post-industrial and globalized settings can be stated as one of the triggers for amateur makers and DIYers to embrace the possibilities of mass customization and open design (Von Busch, 2012).

The ultimate shared goal behind all these approaches to openness and the Maker Movement or DIY movement is that they embrace and spread Open Design and openness as a whole for the democratization of production and creativity in connection to innovation (Dougherty, 2012). Nonetheless, to do so in the Maker Movement Manifesto, Mark Hatch (2013) states nine principles of the movement *Make, Share, Give, Learn, Tool Up, Play, Participate, Support, and Change*; all in the outcome to allow people to make and create while sharing and learning in a playful and fulfilling cyclic process by creating a community and a sense of wholeness to trigger further positive change. The manifesto outlines the movement's goal to provide affordable, user-friendly tools that empower people to access knowledge, capital, and markets while emphasizing community and resources to produce authentic and high-quality things (Hatch, 2013).

Similarly, Balka, Raasch, and Herstatt (2010) discuss the aspects of openness under the terms of *transparency, accessibility,* and *replicability*. They explain that *transparency* denotes the level of information freely available to the community; *accessibility* refers to being able to participate actively in product development; and *replicability* indicates that it should be possible for components to be available individually so that the products can be assembled by the community. If we were to connect the nine principles of the movement (Hatch, 2013), and the terms of Balka et al. (2010), **transparency** would include *Make, Share,* and *Learn*; **accessibility** would include *Tool up, Participate,* and *Support*; **replicability** would include the combination of both with a push for *Change*. Thus, in parallel to these, Aitamurto, Holland, and Hussain (2015) stress that open design covers not only the openness of products but the openness of the process, including all the stages.

The Maker Movement in connection to Open Design has become popular worldwide, but the state of it in Turkey is still in its early stages due to sociocultural and economic factors. The reason for this case in Turkey is that the rapid prototyping and manufacturing tools and processes have been introduced as state policies with a changing political agenda with a new government that shifted its focus to privatization of production and encouraged it to the point of forcing global competition (Hatunoğlu et al., 2011). While the community in Turkey values the *Make* and *Share* principles (see Figure 1), their focus on *Participate* and *Support* requires financial support from internal and external groups (Hatunoğlu et al., 2011). Yet access to tools, resources, knowledge, and technology literacy still poses challenges. Hence, despite the project's aim to be open and transparent, these challenging circumstances inevitably hinder their accessibility and replicability. In light of this, the projects were analyzed regarding their level of openness in terms of *transparency*, *accessibility*, and *replicability* (Balka et al., 2010), and concerning the principles in the Maker Movement Manifesto (Hatch, 2013) in the following sections.

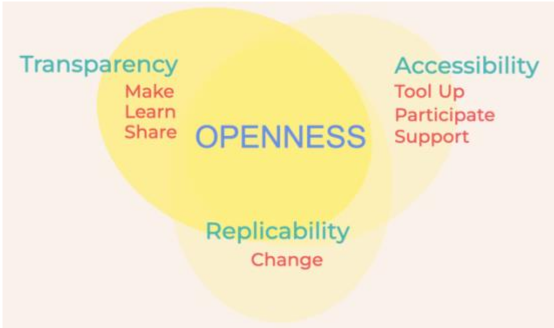

**Figure 1. Adoptation of Hatch's (2013) *Maker Movement Manifesto* and Balka et al.'s (2010) *Aspects of Opennes* for the context of Turkey according to the Hatunoğlu et al. (2011) works.**

## Fluidity of roles: user, designer, maker

When looking at the literature on users and designers' changing roles and identities, the boundaries between amateur and professional seemed to be blurred and diffused into each other. While users are more active and take the initiative about their production and consumption choices (Toffler, 1980; Campbell, 2005; von Hippel, 2005; Leadbeater & Miller, 2004), designers seem to be in more organizational roles that help the maker create comfortably (Inns, 2007). The reason for including more people in the creation of objects lies in need to engage with the products on a different level (Dougherty, 2012) and go beyond just being passive consumers to active agents. Furthermore, emerging technologies in self-production methods enabled makers to make the objects they needed and/or desired (Atkinson et al., 2008).

The presumed roles of users and designers seem to be challenged. For this reason, evaluation of the involvement within the open design projects, maker or DIY projects have been an attractive area for researchers since these acts refer to an intersection point between users and designers where both parties are conducting creative work at some level. To differentiate between the levels of creativity involved in the practices, Sanders (2006) suggested a model with four groups: *Doers, Adapters, Makers, and Creators*. *Doers* spend a minimum amount of interest and skill to accomplish a project and mostly take action to solve a domestic problem and save money. On the other hand, *Adapters* are motivated to express their identity through their works and change the objects in some ways to personalize them. When it comes to *Makers* who seek to create something that did not initially exist, with a strong interest in both the practice and the experience, they are the ones that usually follow some kind of guidance, such as a pattern, instructions, or notes that describe what materials to use and how to put them together. Lastly, *Creators* are the ones who enjoy expressing themselves and innovating; their creative efforts are fuelled by passion, and they have a high experience level. For them, making depends on using raw materials, and they can also operate without patterns and guides. With this categorization in mind, this paper questions which roles we have assumed and how those roles and our backgrounds as design students affected the projects.

## Methodology

This study focuses on six open design projects (see Table 1) created in the *ID736 Open Design and Distributed Creativity* course at Middle East Technical University in Turkey as part of the graduate program in the Industrial Design Department. The course focused on open processes and the potential for alternative modes of production and consumption. All the projects followed similar stages to meet course requirements, and researchers experienced alternative forms of collaboration and designers' roles in decentralized, connected, and creative design processes.

After the theoretical background was settled, researchers were expected to 1) create design projects shared in open design platforms, 2) create projects inspired and adapted from other open design projects, and then share them again in open design platforms. Researchers created one project for each requirement, and in the end, six different projects were completed (see Table 1). This paper provides a critical reflection on the projects and examines their degrees of openness by using Balka et al. definition of openness. Also, the fluidity of project makers' roles between professionalism and amateurism was examined together with the circumstances of the local settings. Although the motivations and methods of the six open design projects fall into different areas, they share the aim of creating and experiencing the open design process involving designing, digitizing, fabrication, and documentation. To analyze the projects, researchers used their notes from the process, reflection papers written at the end of the course, and the interactions received on the open design platforms where the projects were uploaded. This paper is positioned in a discussion area where projects are discussed in their level of openness within the local context and the designer's fluid role between professional and maker within the educational institution rather than being a research paper based on the primary data. Rather than for generalization purposes, this study presented as a small case to allow us to discuss the openness, level of involvement, and fluidity of roles in the context of design education in Turkey.

## Reflection on open design projects

Throughout the six projects examined in this study (see Figure 2), the open design approach was utilized at various stages of the design process. The initial phase involved searching through open design platforms; documenting and sharing the projects' process and outcome on the open design platforms; engaging with the community through comments, and finally following a collaborative process in the class through discussions before, during, and after the project. However, these platforms have an issue of not having a united language and format they use. Therefore, in the class, a standard format including the project explanation, the mistakes, difficulties, and the steps of the project was established. According to this format, all the processes and learning experiences were transferred to the communities through open design platforms.
The sources, materials, instructions, and project stages were openly shared in the Instructables and Thingiverse platforms, available to the community for no charge. People can also make revisions and interventions on the projects and use and change however it suits their needs. Therefore, considering the openness aspects suggested by Balka et al. (2010), projects met the *transparency* and *replicability* terms while failing to provide *accessibility in the sense that* the processes were not accessible for people to participate in the design and production stages outside of the class, and even though the tools and methods used for design and production of

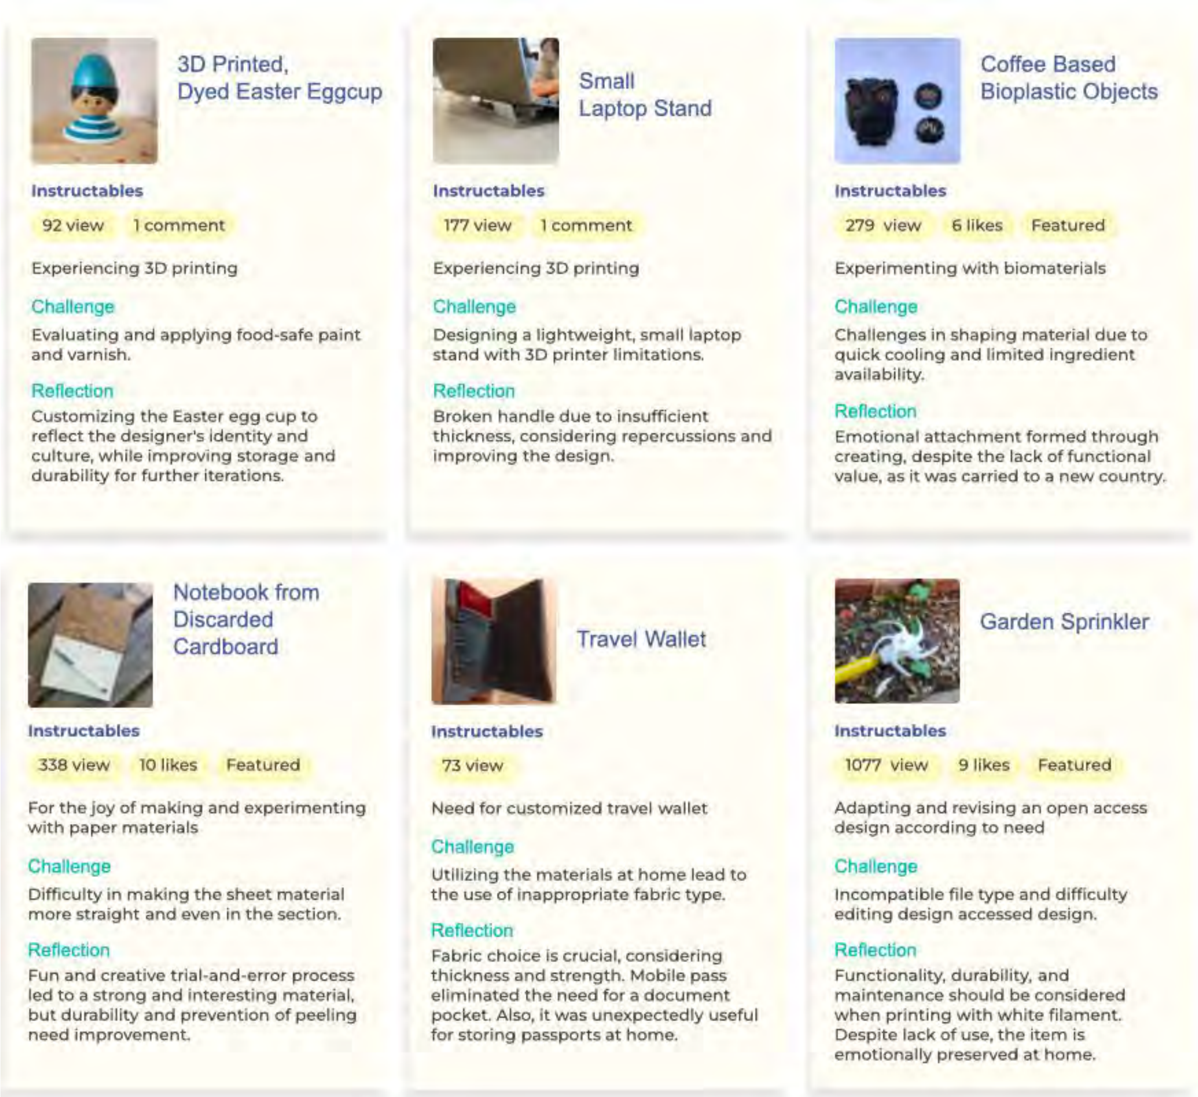

**Figure 2. List of open design projects developed in the course.**

the projects were explained, the reality of uti whether the users of the platform all are able to lize them in the sense of knowledge and their access to the resources is unknown.

It was discovered that *accessibility* -as one of the principles of openness- was crucial since it strongly relates to the local context. As stated in the theoretical approach, the Turkish Maker Movement has a long way to go, and economic and social circumstances in the country make the democratization movement into a hobby that only those with the privileges and means to participate and sustain can be a part of. At least in digital processes like 3D printing and other rapid prototyping methods, not only the availability of such opportunities within one's reach but also the economic aspect of it is an issue. Considering Turkey's economy and inflation rate in relation to Western currencies that dominate the price levels of many manufacturing methods, accessibility of technologies and materials needs to be considered as a limitation to the open design projects. Despite being in a university context where tools are relatively cheaper and more accessible along with the available resources and knowledge, the economic aspects still required consideration, especially when errors occurred. Even though these errors resulted in a broken product (Laptop Stand project) or size issues during modeling and printing (Garden Sprinkler project) (see Table 1), they were not reproduced but tried to be repaired.

The other discussion point of the open design projects was related to the researchers' changing, blurring, and clashing roles as designers, students, and makers. In addressing the question of whether designers would continue to safeguard their designer identity or create freely as users when designing for openness and conducting open processes, it becomes apparent that the designers' identities are not fixed or limited to a specific role. Designers represent their knowledge, and their experiences, thus themselves as a whole, and their roles can be subject to fluidity and temporal shifts. Therefore, the designers' assumed role in creative endeavors is fluid and complex, with an encompassing wholeness that transcends through different definitions and labels. However, the question of how designers define themselves when designing for openness and conducting open processes is more complex. Their definition of themselves may change according to their goals and mood. Open design projects can be a challenge for designers to be more open to the possibilities without obsessing about the beauty of the end product (not only aesthetically pleasing but also functionally and semantically fulfilling) but to explore the process, getting familiar with the self-production phases to have a better understanding of the active users with whom they will collaborate much more in the future.

One of the researchers observed that they enjoyed the making process as if it was an amateur pastime (Von Busch, 2012) or productive leisure (Atkinson, 2011) since they weren't aiming to achieve meaningful, fully functioning products. Although they were aware of the exploratory side of the projects, they were still displeased with the end result since they couldn't fully lose their designer identity. They realized that it might not be quite possible to be detached from a designer identity while designing even a small thing while acting as a maker. They were aware of its weak points in various aspects and thought that they needed further iterations to be called as products. Maybe the stigmatized product beauty concepts of trained designers also affect the perception of self-made objects. Therefore it is hard to set aside these perceptions and see the project process as a making and sharing process only.

The effect of formal design education and conducting these open design projects in a graduate course being set in a design department created another level for the discussions in this paper. As mentioned, conducting an open design project can require access to certain materials and technological equipment. In this case, the availability of a workshop area with 3D printers, relevant materials, and equipment in the university setting provided easy access for the researchers. Also, guidance from the course instructor, peer feedback in class discussions, and technical support from the workshop instructor supported the open design process. Course requirements also had an effect on the open design projects in terms of planning the process and time limitations. Since researchers needed to finish and submit the projects in specific time frames for the course, the goal and the results were adjusted to this condition.

## Conclusions

The study indicates two primary results see Figure 3). Firstly, we analyzed the projects regarding their level of openness in terms of *transparency, accessibility, and replicability* (Balka et al., 2010), and Maker Movement Manifesto principles (Hatch, 2013). Accordingly, it is discussed that the projects fulfilled the *Share, Support*, and *Participate* aspects in the process of *Make* and *Learn* with the help of the implementation of it in the process of the course, they failed to achieve *accessibility,* which lies in the foundation of *Tool up* principal due to the economic and social conditions in Turkey. To resolve some of the challenges that these conditions put on the open design processes in Turkey, the fundamental principle of *Change* should be emphasized in the community and academic scene in Turkey. On the larger lens, for these open design processes and the final projects to be sustainable in both the economic and environmental sense in Turkey, more consideration should be given to them in terms of being resourceful and functioning.

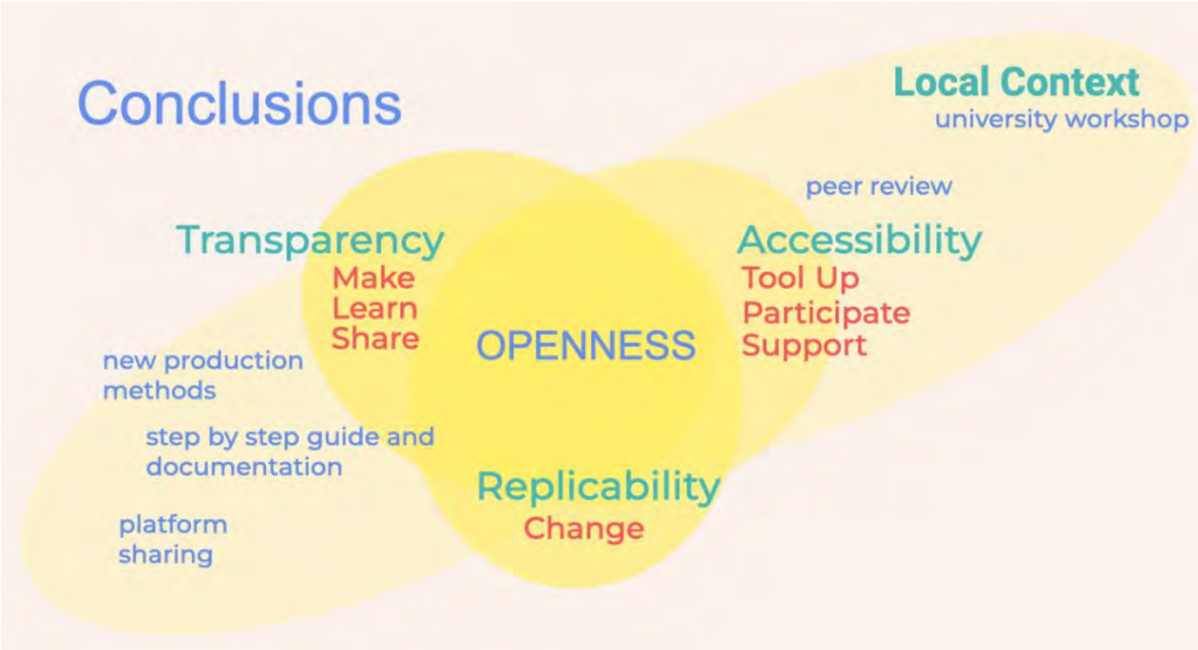

**Figure 3. Adoptation of Hatch's (2013) *Maker Movement Manifesto* and Balka et al.'s (2010) *Aspects of Opennes* for the context of this research.**

Secondly, it identified that the researchers' roles and backgrounds affected the process. It was realized that the creative involvement of the researchers cannot be identified with Sanders' model (*Doers, Adapters, Makers,* and *Creators*) since all the roles are fluid in their nature and one can have multiple roles while conducting an open design project. Designers may still protect their designer identity, but they may also produce freely as users, depending on the project's requirements and roles.
Finally, as designers and makers, we can contribute to openly sharing designs, knowledge, and experience; however, if those interested in and wanting to access the projects cannot due to uncontrollable economical and social circumstances, we must delve deeper into the root causes. Although the *change* aspect of the movement has not been fully implemented in Turkey, those who know and are proficient in open design concepts and who are active in these communities can push for change wherever possible.

### Acknowledgments
Open design projects conducted in this research were done during a graduate course entitled *ID736 Open Design and Distributed Creativity* at the Industrial Design Department of Middle East Technical University in Ankara, Turkey, during the Spring semester of 2021-2022. We are thankful to the course instructor Yekta Bakırlıoğlu, Ph.D. for his time and invaluable feedback. Moreover, we are grateful for the interactions received for our projects and projects that inspired us in the first place on Instructables and Thingiverse.

# Measures to Enhance a Circular Plastic Economy in Europe

**Malin zu Castell-Rüdenhausen[(a)], Tatu Marttila[(b)]**
a) VTT Technical Research Centre of Finland Ltd., Espoo, Finland
b) Aalto University, Espoo, Finland

**Keywords**: Plastics; Circular economy; Recycling; Recyclability; Decision-making.

**Abstract**: The transition to a circular plastic economy requires increasing recycling rates and well-functioning markets for secondary plastics. Today, lack of ecodesign considerations in manufacture leads to poor recyclability at end-of-life phase for most plastic products, leaving incineration and export as only waste management options. We have a somewhat good insight into the external barriers related to increasing plastic recycling. However, the internal barriers of the plastic sector remain unclear, as does also the means for overcoming barriers and facilitating a transition to a circular plastic economy. This study investigates the hinders currently preventing efficient plastic recycling and solutions for overcoming these. The objective of study is to generate recommendations for creating a well-functioning and safe plastic recycling system in Europe. The focus is on plastic waste in end-of-life vehicles (ELV), waste electronics and electrical equipment (WEEE) and construction and demolition waste (C&DW). Data collection was implemented in the form of semi-structured interviews. The results from the interviews were combined into a set of hinders with solutions for tackling these presented along a simplified value chain. These were lumped into four solutions, namely (i) enhancing the collection and recycling efficiency, (ii) increasing the recycling capacity and recyclate markets, (iii) enhancing the positioning of chemical and physical recycling technologies, and (iv) enhancing the recyclability of plastic waste. To facilitate implementation of the solutions, actions for legislative revision, policy implementation and standardization activities were presented.

## Introduction

Today, significant volumes of plastic waste are incinerated and exported due to lack of European capacity and economic incentives for recycling. Furthermore, lack of ecodesign considerations in product design and manufacture has led to poor recyclability at end-of-life phase for most products with embedded plastics.

Today, we have a somewhat good insight into the external barriers related to increasing plastic recycling, these are mainly recyclability (waste streams are often heterogeneous since plastic products are complex and contain multiple materials), hazardous material content (such as flame retardants and plasticizers), traceability (uncertainty about recyclate quality), price (the low price of primary materials and the high costs of recycling), and quality degradation in mechanical recycling (the polymer length is degraded) (European Environment Agency., 2021; Material Economics, 2018; Wahlstrom et al., 2019; zu Castell-Rüdenhausen et al., 2022). However, the internal barriers within the plastic sector remain unclear, as does also the means for overcoming barriers and facilitating a transition to a circular plastic economy.

This study looks at recycling and recyclability from both a technical and a design perspective to facilitate reaching the targets of the Plastic Strategy, more specifically the targets of recycling more than half of plastics waste generated in Europe by 2030, to four-fold increase the demand for recycled plastics in Europe, and phasing out the exports of poorly sorted plastics. This study focuses on plastics in end-of-life vehicles (ELV), waste electronics and electrical equipment (WEEE) and construction and demolition waste (C&DW).

The objective of study is to generate recommendations and to find where in the value chain these should be targeted to give best results. More specifically, the aims of the study are (i) to identify hinders currently preventing efficient plastic recycling, (ii) to identify solutions that facilitates circularity in the sector, (iii) to identify the internal decision-making regarding circularity in the value chain, and (iv) to present targeted actions for creating a well-functioning plastic recycling system in Europe.

## Background

Increasing recycling rates and well-functioning markets for secondary raw materials prerequisites the implementation of a circular economy, as also highlighted in the European Green Deal, Circular Economy Action Plan and European Strategy for Plastics in a Circular Economy (European Commission, 2019, 2015, 2020a, 2018a). The Plastic Strategy aims to support more sustainable and safer consumption and production patterns for plastics by transforming the way plastic products are designed, produced, used, and recycled in the EU (European Commission, 2018a). A key objective of the strategy is to improve the recyclability of plastics.

The promotion of a circular economy has resulted in increasing pressure on recycling in the EU. Strict targets are set in waste-specific directives (European Commission, 2018b, 2018c, 2008, 2020b). Standards aim at presenting best recycling practices by providing guidelines for fulfilling the legislative requirements (CENELEC, 2017; EUCertPlast, 2023; Plastic Recyclers Europe, 2023; WEEELABEX, 2023). The legislative framework was studied by zu Castell-Rüdenhausen et al. (2021), illustrating that different legislation and standards apply for different actors and different phases of the value chain, see Figure 1.

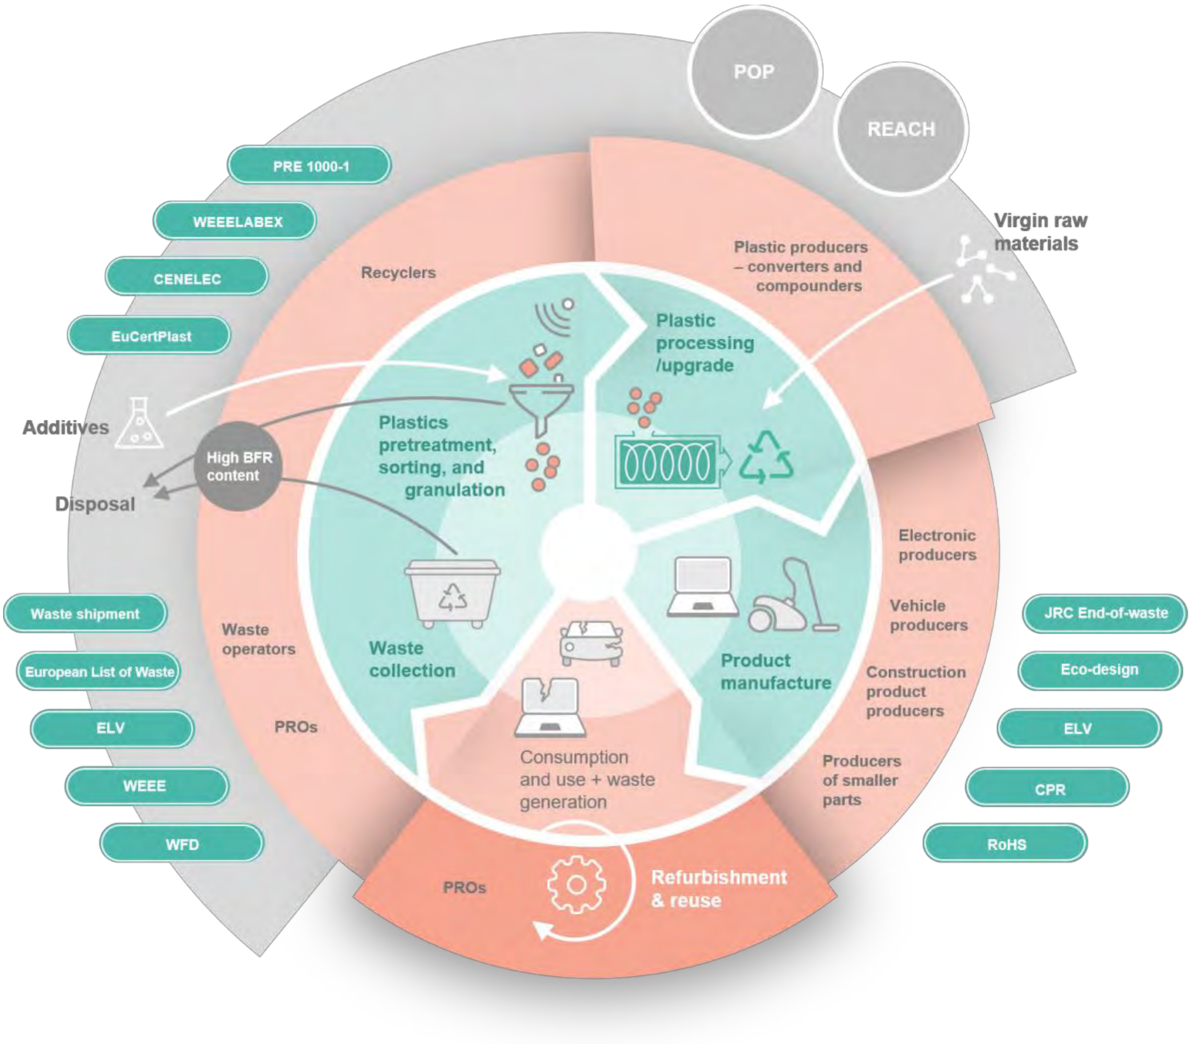

**Figure 1. The plastics policy value chain, indicating the impact of the European legislation and standards (zu Castell-Rüdenhausen et al., 2021).**

## Methodology

Data collection was implemented in the form of semi-structured interviews. The interviewees represented all targeted sectors (WEEE, ELV, CDW), as well as the whole value chain of actors. The interviewees were selected within project affiliate networks. The conduction of interviews used a structured outline that was distributed prior to the interviews together with complementary materials on the policy landscape in EU. The interviews lasted between 1,5–2 hours, enabling in-depth conversation of all topics addressed. All interviews were recorded and transcribed. The interviews started with documenting the background and employment of the interviewee to enable better understanding of the interviewee's perception of the industry, assigning biases to the interviewee, and if previous experience impacts their insight. This introductory part was followed by guided conversation following the outline.

The first topic addressed hinders currently preventing efficient plastic recycling. The objective was both to identify the internal barriers that prevent change from within, as well as external barriers according to the different stakeholders. Furthermore, differing opinions between stakeholders and different stages of the value chain were identified and highlighted. This topic was further divided into four sections. The section on market challenges focused on the transition to a profitable recycling industry; key questions addressed the role of pricing and costs, and the role of policy instruments. The section on challenges in recycling focused on technology challenges, feedstock quality, policy instruments, and the impacts of transboundary movements of waste. The section on design addressed topics such as the use of recycled plastics in design and manufacturing and design of recyclable products. The section on information availability focused on traceability and the management data such as information availability of product and material contents.

The second topic addressed actions and instruments to improve circularity. The objective was to identify means for overcoming barriers and bottlenecks related to legislation, technology, and economy. The interviewees elaborated on instruments that are known to improve the recyclability of products, recovery rates of collection systems, and market demand for recovered materials. Some instruments were presented in the background materials, more precisely green public procurement, mixing obligations, expansion of extended producer responsibility schemes, information accessibility, and material specific recycling targets. The interviewees were encouraged to elaborate on the efficiency of as well these, as other instruments.

The third topic addressed the structures for internal decision-making in the value chain. The objective was to give a better understanding of where decisions regarding circularity are being made, enabling understanding the internal barriers within the plastic sector, and identifying targeted actions with high impact, that could drive for closed material loops from within. The interviewees were asked to pin-point where decisions regarding the use of secondary raw materials, and the recyclability of products are being made. They were also asked to elaborate on the implementation and follow-up on the decisions, whether they get implemented or why not, and what the key bottlenecks for decision-making and implementation are.

## Results

The results from the interviews were combined into a set of hinders with solutions for tackling these (Table 1). These are presented along a simplified value chain, as illustrated in Figure 2.

The risks and economic burdens related to the use of recyclates was highlighted throughout the value chain. Brand owners were found as the key stakeholders for promoting circularity in the sector, since they are responsible for design and the choice of raw materials, as well as design related to recyclability. It was, however, highlighted that designers still lack knowledge on the requirements of the recycling processes and how to design for better recyclability.

The role of manufacturers was also highlighted in the decision-making for circularity, as they can choose which granules to use in production. It became evident, that if brand owners are not actively asking for secondary raw materials, the manufacturers will commonly not take on the risks or economic burdens related to these.

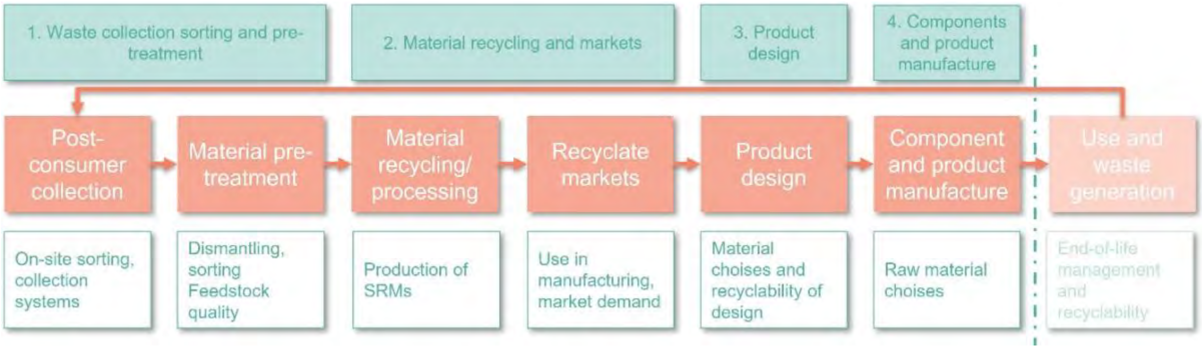

**Figure 2. The value chain representation of the results from the interviews.**

| Hinders | Solutions |
|---|---|
| **Waste collection, sorting, pre-treatment** | |
| Volumes are very small and the quality is not stable. | Increase collection and recycling volumes to gain a better and more stabile feedstock. |
| Many post-consumer polymers cannot reach economy of scale for recycling. | Increase collection and recycling volumes to make recycling of non-commodity polymers feasible. |
| Exporting plastic waste prevents increasing the European recycling capacity. | Prevent the export of plastic waste. |
| Polymers are mixed in collection, preventing recycling efficiency. | More intense segregation of colors and polymers. |
| Collection schemes cannot supply increasing demands for feedstock. | Increase separate collection capacity. |
| **Material recycling and markets** | |
| Hazardous substances prevent recycling. | Reduce the use of hazardous additives.<br>Develop recycling technologies that remove hazardous substances. |
| Poor recyclability due to multilayer structures, poor separability, poor quality of the feedstock and lack of technology solutions for treating mixed waste streams. | Implement design for recycling.<br>Implement physical and chemical recycling for difficult-to-recycle wastes. |
| Poor profitability of recycling | Economic incentives for recycling |
| Lack of awareness of chemical or physical recycling as an option to landfill/incineration/export for hazardous fractions. | Increase knowledge of physical and chemical recycling among recyclers. |
| Quality deteriation of the polymers in the mechanical recycling process. | Combine chemical and mechanical recycling to ensure long-term quality stability. |
| Lack of recycling capacity to cover future demand for recyclates. | Economic incentives for expanding recycling capacity |
| **Product design** | |
| The overall costs related to the use of recyclates are higher in short term. | Economic incentives for the use of recyclates |
| Designers lack knowledge on design for recycling | Increase awareness on design for recycling |
| Lack of data on recyclate properties prevents wider use | Support data generation and harmonisation, and material standards for recyclates |
| **Components and product manufacture** | |
| Recyclates more expensive to use than virgin granules | Financial incentives for using recyclates |
| Processing problems with recyclates due to deviations in quality | Improve recyclate quality and data |
| Manufacturers prefer not to use recyclates. | Support the use of recyclates. |
| Fluctuating prices of recyclates | Decouple recyclate prices from virgin prices |

**Table 1. The identified hinders and solutions for circularity.**

To facilitate implementation in practice, actions for legislative revision, policy implementation and standardisation activities are presented to implement the solutions presented in the previous section, aiming to create a well-functioning and safe plastic recycling system in Europe. The incentives are spread throughout a simplified value chain and targeted where they give best results (see Figure 3).

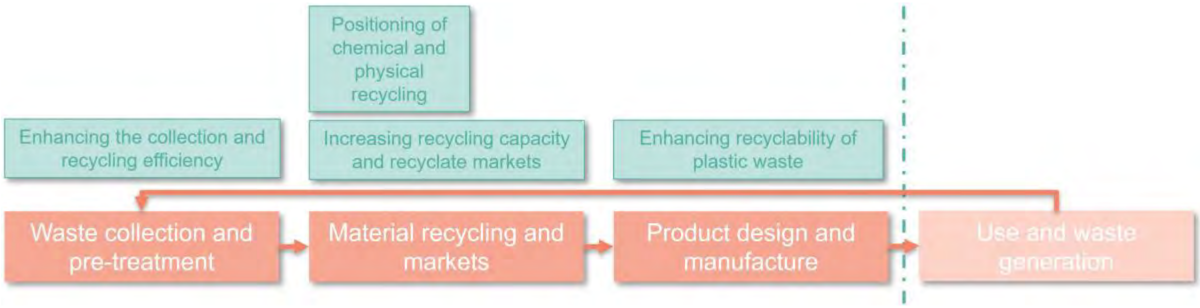

**Figure 3. Solutions for increasing the circularity in the plastic sector.**

Today, collection volumes are very small with fluctuating quality. Inefficient collection of waste results in losses of valuable materials. With more focus on end-of-life management, by increasing collection volumes and intensifying segregation, a better feedstock quality for recycling can be achieved. The following actions can enhance the collection and recycling efficiency:

- ***Legislative revision***: reporting on actual recycling output.
- ***Legislative revision***: introduction of material specific waste recycling targets in the waste directives.
- ***Policy implementation***: encourage sorting at site and more intensified segregation.

Significant volumes of plastic waste are exported from Europe due to lack of European capacity and economic incentives for recycling. Also, there is no EU wide end-of-waste criteria that would remove the administrative burdens of wastes and harmonize the quality of recyclates. The prevention of exports can support increasing the domestic recycling capacity while harmonization of recyclate quality would support the recyclate markets. The following actions can support increasing the recycling capacity and recyclate markets:

- ***Legislative revision***: the waste shipment directive to prevent exports of plastic waste from Europe.
- ***Policy implementation***: introduce EU wide end-of-waste criteria for plastics in CE road maps.
- ***Standardisation activity***: harmonization of recyclate quality

The recycling of mixed and hazardous fractions is prevented by lack of awareness among recyclers of chemical or physical recycling. Also, quality deterioration of polymers in mechanical recycling prevents multiple recycling loops. Chemical recycling can support mechanical recycling and ensure long-term stability of polymer quality. The following actions can enhance the positioning of chemical and physical recycling technologies:

- ***Policy implementation***: increase awareness of emerging recycling technologies

By increasing knowledge on design for recycling, manufacturers could produce recyclable products. Hazardous substances, multilayer materials, and some manufacturing methods, such as gluing, leads to poorly recyclable waste. The following actions can enhance recyclability of waste:

- ***Policy implementation***: increase awareness on design for recycling.

The demand for recyclates need to increase to support circular material loops. Mandatory secondary material use would increase the demand for recyclates. The following actions can enhance the demand for recyclates:

- ***Legislative revision***: product directives to include mixing obligations for certain products.
- ***Policy implementation***: ensure sufficient recycling capacity
- ***Standardisation activity***: harmonization of recyclate quality

## Discussion and conclusions

The results of the interviews showed favor towards increasing the use of recyclates, despite some extra expenses for the industry. Problems related to quality and security of supply was suggested to be solved by increasing the European plastics recycling volumes, introducing new technologies to both recycle hazardous and mixed waste streams, and by preventing plastic waste exports. The interviewees called for policy measures to hinder the export of plastic waste and to increase the European recycling capacity.

A significant problem today is the absence of end-of-life considerations in design and manufacture. Ecodesign is a prerequisite for plastics circularity – yet policy focus is strictly on waste management. It became evident in the interviews that designers lack knowledge of the requirements of the recycling processes. Thus, a key hinder for increasing recycling rates is also the lack of ecodesign considerations and recyclability.

To tackle the recyclability problems of plastic waste, significant efforts are now put on technology development to enhance the efficiency of recycling, and on policy-making to steer waste towards recycling. However, policies on product design and recyclability requirements have yet not become mandatory. Today, the proposal for the new Packaging and Packaging Waste Regulation (European Commission, 2022) is the first European policy document addressing design and recyclability requirements for producers.

To support the transition to plastics circularity, European policies aim to create economic incentives to increase the European recycling capacity. However, if e.g. mixing obligations was to be introduced, it should be noted that the supply need to meet the demand and that the feedstock must be controlled to prevent mismanagement. Also, in the production of some products, incorporation of recyclates may be prevented by strict safety requirements. Thus, mixing obligations need to be considered on a case-to-case basis.

In the study, brand owners were identified as key stakeholders in promoting circularity in the sector, being responsible for design both to use recyclates as raw materials, and for the products recyclability after end-of-life. However, brand owners struggle with risks and uncertainties related to the use of recyclates, such as lack of data on recyclate properties. And although recyclates may be cheaper to purchase, the overall costs are somewhat higher in short term. This relates to products and processes needing to be redesigned for new material properties. However, the image benefits from the use of recyclates was not seen as bringing a monetary value to cover for the expenses from changing raw material.

The role of manufacturers was also highlighted in the decision-making for circularity, related to the choice of raw materials. It was found that brand owners must actively promote secondary raw materials, but manufacturers have the final choice. However, it was concluded that large brand owners can influence the raw materials use, whereas smaller customers cannot.

Today, recycling often cannot reach economy of scale. Mainly post-consumer polyolefins and PET are available on the market, whereas other recyclates are mainly post-industrial. Increasing the separate collection to generate larger feedstock volumes would make recycling other than main polymers feasible.

To improve the circularity of the plastics sector, there is a need to increase the demand for recyclates that would enable capacity investments for recycling in Europe. Today, Europe experiences significant loss of non-renewable materials due to incineration and export of plastic waste. These should be better utilized while also contributing to EU's self-sufficiency for raw materials and ensuring the replacement of fossile raw materials.

# PLATE2023
# EXHIBITIONS

# REPAIR Exhibition

**The REPAIR exhibition** was a part of the PLATE2023: Product Lifetimes and the Environment conference. We invited PLATE researchers to exhibit their take on the theme of repair. This encompassed repairing products, design, systems, consumption, sustainability balance, business models and policy actions.

The exhibition included fourteen diverse works, which explored solutions for extending product lifetimes in practice, through repair. The works generated discourse and embraced the opportunities that come hand-in-hand with a culture of repair.

**PLATE2023**
www.plateconference.org

## Mending

Shirley McLauchlan's hand stitched embellishments on deadstock garments responded to the shift in consumers' appetites for visible mending, while Marta Konovalov rediscovered wisdom from traditional mending techniques in a series of artefacts from repair workshops. Iryna Kucher showcased a series of 3D printed mending tools and their potential applications.

## Change and transformation

A large-scale textile piece by Dr. Laetitia Forst and Professor Becky Earley was designed for disassembly, and it enables modifications of textiles and garments in culturally relevant ways, based on specific geographic contexts. Another textile piece by Colette Paterson was designed with future mending in mind, woven with guidelines which aid the user in mending, patching and reinforcing all or part of the garment or product that it becomes.

## Repair through re-purposing

Katherine Townsend, Eloise Salter and Karen Harrigan targeted repair problems which lead to textile waste streams, with an installation comprising fashion and textile concepts, samples and prototypes developed from used PPE isolation gowns destined for landfill. Miriam Borcherdt's garment series used existing stock as building blocks for fashion production, exploring scalability through the practices of redesign and remanufacture.

## Communal aspects of repair

Sabine Lettman presented an outfit which aims to 'repair' human disconnectedness, intensify relationships and emotionally bridge geographical distance through shared wearing experiences. Ines Güsser-Fachbach presented an online network which connects consumers with companies that can repair goods such as household appliances, clothing, accessories, jewelry, IT equipment, smartphones, bicycles and furniture, and which also enables job exchanges, funding opportunities and events in the repair sector.

Johannes Scholz and Isabel Ordóñez showcased an open-source card game which focused on repairing our relation to waste by placing players in the role of material recovery initiatives, like those currently present in many cities, while Aisha Susanne A. Hjorth Nielsen presented a series of interviews and artefacts collected from 'repair cafes'. Dr. Tung Dao, Prof. Tim Cooper and Dr. Matthew Watkins presented findings on the consumer repair journey, highlighting innovative business opportunities for the promotion of repair practices.
Analysis and reflection

Hannu Savolainen, Angelina Korsunova and Kati Berninger showcased findings from a research project which maps the most and least repaired product types in Finland, while Dr. Elizabeth Chamberlain and Dr. Beatriz Pozo-Arcos exhibited a series of electronic devices, highlighting both the positive and negative aspects of the development of repairable design, alongside the tools and guides needed to take the items apart.

Product Lifetimes And The Environment

# Repairing the Fashion System

The fashion system is broken, from a sustainability viewpoint. At Aalto University, we aim to find solutions to improve and repair the textile and fashion sectors. This work happens in multidisciplinary research collaborations but also in collaborations with industry, business, consumers and policy makers.

Fashion/Textile FUTURES research group, Associate Professor Kirsi Niinimäki

**NEW COTTON project** https://newcottonproject.eu/

It is currently estimated that only 2% of post-consumer textiles are diverted to fibre-to-fibre recycling. The fashion industry urgently needs scalable solutions, yet the creation of circular materials to decrease dependency on virgin material has historically been proven challenging, with a truckload of textiles being landfilled or burned every second. Although there have been many pilot schemes, no organisation has been able to address the problem alone. The New Cotton Project aims to demonstrate a potential for commercial circular garments and to build an ecosystem understanding for textiles circularity. The project is run by Infinited Fibre Company IFC.

**T-REX project** https://trexproject.eu/

T-REX Project brings together 12 major players from across the entire value chain to create a harmonised EU blueprint and business opportunities for closed loop sorting and recycling of household textile waste. The focus is on cellulose, polyester and polyamide materials.The project is run by Adidas.

**FINIX project** https://finix.aalto.fi/

Through our multidisciplinary research we aim to make a system level change in textile and fashion sector. "The fast fashion industry cannot be fixed with material substitutions and eco-labels. Instead, the textile industry must be radically reconstructed to minimise natural resource intake and waste production, requiring that material and product lifetimes are maximized. We outline steps that must be taken to materialize this change"

(Sahimaa, O., Miller, E.M., Halme, M., Niinimäki, K., Tanner, H., Mäkelä, M., Rissanen, M., Härri, A., Hummel, M. (2023) The only way to fix fast fashion is to end it. Nature Reviews; Earth & Environment).

**SUFFICIENCY: Resizing Fashion for a Fair Consumption Space report**
https://hotorcool.org/unfit-unfair-unfashionable

"Current trends in fashion consumption, in particular fast fashion, cannot be maintained if we aim to achieve a fair and just transition to climate neutrality (i.e., net zero greenhouse gas emissions). Mounting scientific evidence reveals the vast extent of negative environmental and social impacts associated with fashion consumption, as well as the differing responsibilities of consumers in high- and low-income countries and groups. This report contributes to filling the knowledge gap that arises from prevailing climate scenarios related to fashion. The report discusses fashion "sufficiency", extending the concept of a fair consumption space to fashion and making quantitative estimates within the available carbon budget for G20 countries to keep their fashion consumption footprints below the 1.5-degree target."

(Coscieme, L., Akenji, L., Latva-Hakuni, E., Vladimirova, K., Niinimäki, K., Henninger, C., Joyner-Martinez, C., Nielsen, K., Iran, S. and D Itria, E. (2022). Unfit, Unfair, Unfashionable: Resizing Fashion for a Fair Consumption Space. Hot or Cool Institute, Berlin.)
