# PLATE2023

## The 5th Product Lifetimes and the Environment Conference in Aalto University, Espoo, Finland, 31 May – 2 June, 2023

The 5th international PLATE conference (Product Lifetimes and the Environment) addressed product lifetimes in the context of sustainability. The PLATE conference, which has been running since 2015, has successfully been able to establish a solid network of researchers around its core theme. The topic has come to the forefront of current (political, scientific & societal) debates due to its interconnectedness with a number of recent prominent movements, such as the circular economy, eco-design and collaborative consumption. For the 2023 edition of the conference, we encouraged researchers to propose how to extend, widen or critically re-construct thematic sessions for the PLATE conference, and the paper call was constructed based on these proposals. In this 5th PLATE conference, we had 171 paper presentations and 238 participants from 14 different countries. Beside of paper sessions we organized workshops and REPAIR exhibitions.

### Conference Chair:

Associate Professor Kirsi Niinimäki, Aalto University

### Conference academic committee:

Professor Conny Bakker, TU Delft
Professor Minna Halme, Aalto University
Associate Senior Lecturer Jessika Richter, Lund University
Associate Professor Mikko Jalas, Aalto University
Coordinator Yumiko Henneberry, TU Delft

### Local organizing committee in Aalto University:

Postdoctoral Researcher Kirsti Cura
Postdoctoral Researcher Emmi Pouta
Master student Chloé Hartmann
Fashion/Textile FUTURES research group

### THE PLATE CONSORTIUM

Aalborg University, Denmark
Aalto University, Finland
Delft University of Technology, The Netherlands
Lund University, Sweden
Nottingham Trent University, United Kingdom
Fraunhofer Institute for Reliability and Microintegration (IZM), Germany
University of Limerick, Ireland

# Knowledge and power:

## The evolution of research into product lifetimes

Over the past decade there has been a substantial growth in research relating to product lifetimes. By contrast, in the early 1990s a report entitled ***Beyond Recycling: The longer life option*** revealed very little academic activity in the field, and over the next 20 years it grew only slowly. Around a decade ago, however, a time when interest in the circular economy concept was rapidly expanding, the need for a series of clearly focussed conferences to bring together researchers with expertise relating to product lifetimes became apparent. Launched in the UK in 2015, PLATE conferences have since been held biennially, each in a different country, and attracted over 650 participants.

In his presentation, Tim Cooper, who initiated the conference series, will reveal the findings of a recent study on the evolution of research on product lifetimes, based on a review of papers presented at past PLATE conferences, which now total nearly 400. The study team explored not only the content of papers but the background of their authors, enabling a comprehensive overview of academic work over the past decade.

Tim will highlight trends in the aims and methods of conference papers, the types of products addressed, and the extent to which research has been framed in the context of the circular economy. He will identify the location of researchers, their academic disciplines, the extent of collaboration between research institutions, and how conference papers have been used to shape and disseminate knowledge, including transmission into peer reviewed journal articles.

Academic discourse on product lifetimes looks set to grow as public pressure mounts for the principles of the circular economy to be put into practice. Tim will argue that the PLATE community has a vital role to play in ensuring that decisions made by governments, companies, campaigners and consumers are based on sound knowledge derived from high quality research.

***Tim Cooper*** is Emeritus Professor of Sustainable Design and Consumption at Nottingham Trent University. Having started his career as an economist in the construction industry, his first study on product lifetimes, *Beyond Recycling*, was published in 1994 by the New Economics Foundation. He began his academic career at Sheffield Hallam University, and was awarded a Chair at Nottingham Trent University in 2010. His book *Longer Lasting Products*, published the same year, established his reputation as an international authority on the lifetime of consumer goods. He initiated the biennial series of PLATE (Product Lifetimes and the Environment) conferences in 2015, serving as Conference Series Chair until his retirement in 2022.

Tim's research has been funded by the European Commission, Council of Europe, Defra, WRAP, the EPSRC and ESRC. It has explored product lifetimes from a range of perspectives, including design, marketing, business models, behavioural change and public policy, and has addressed a range of industry sectors, notably clothing, appliances, vehicles and furniture. Tim has advised the European Commission (DG Justice and Consumers) and European Economic and Social Committee, and has presented evidence to various UK Government committees, most recently the House of Commons Environmental Audit Committee inquiries into *Electronic Waste and the Circular Economy and The Sustainability of the Fashion Industry*.

Tamar Makov

# The hidden environmental costs of consumer product returns

During the 2020 holiday season alone, US consumers sent more than one million products back to retailors each day(!). Consumer returns are a particularly challenging issue in e-commerce where as many as 20%-40% of all products sold are returned. While many consumers consider return policies to be a key factor in their purchase decisions, few seem realize that the products they send back don't necessarily make it back to the shelf. Instead, many returns travel through a complex reverse logistics supply chain, at the end of which some are resold via outlets and secondary markets at a fraction of their original retail price, while others are recycled, donated, or sent directly to incineration.

Beyond the added transport and waste associated with the post-return lifecycle stages, disposing of brand-new perfectly functional products also squanders the embodied materials and energy invested in their production and distribution. While the environmental impacts of eCommerce are well discussed, returns are seldom included in analyses. As a record number of households adopt eCommerce following the global pandemic, gaining a better understanding of the environmental implications of such a massive shift in consumption patterns is both timely and imperative.
Building on a unique dataset covering over 600,000 apparel items returned in the EU, semi-structed interviews with industry experts, and a comprehensive literature review, we use data-science methods and LCA, to map the flows of returned items across the post-return supply chain and assess the full lifecycle environmental impacts of product returns. Our results suggest that the embodied impacts associated with producing items that are never used far surpass the direct emissions associated with transport, processing and packaging of returned products. To the best of our knowledge, this work presents the first attempt to quantify the environmental impacts of product returns from a full lifecycle perspective.

Dr. ***Tamar Makov*** investigates the potential to address social and environmental challenges through sustainable business practices, technologies, and entrepreneurship. Adopting a systems approach, she draws from the fields of Industrial ecology, Data science, and Behavioural economics, and combines methods including Life Cycle Assessment (LCA), machine learning, and psychological experiments. Her goal is to generate insights informing theory, policy, and real-world decision making on issues including sustainable food systems, the circular economy, and digitalization.

Makov's work has been published in high impact journals including *Proceedings of the National Academy of Sciences (PNAS), Nature Climate Change, and Nature communications*, and is funded by the Alfred P. Sloan Foundation, Internet Society Foundation, Israeli Science Foundation (ISF), and the German - Israeli Foundation for Scientific Research and Development (GIF). Makov is the head of the Circular Economy lab and a faculty member at the Guilford Glazer Faculty of Business and Management and the Goldman Sonnenfeldt School of Sustainability and Climate Change at Ben Gurion University. She holds a PhD and MA in Environmental Management from Yale University, and a B.Sc. in Nutrition science from the Hebrew University of Jerusalem.

Thomas Nyström and Anneli Selvefors

# Future Adaptive Design - designing products for circular business models

A growing number of companies are investigating how to reduce the environmental load and capture financial values through new business models driven by product longevity. However, such a shift entails a multi-dimensional transformation and previous research highlights several challenges related to, for instance, ensuring the viability of business models and value propositions, designing products fit for longevity, and creating pleasant user experiences. Product and organizational complexity can also make it especially difficult to explore circular business models that challenge the current linear business logic.

In their presentation, Thomas and Anneli will highlight opportunities and challenges companies face when pursuing new business models based on extended product longevity. Building on several research projects, they will discuss what implications extended product lifetime has for product and service design, business, and organization. Learnings show that moving away from the prevalent focus on minimizing manufacturing costs, to a focus on preserving product values and reducing both lifecycle costs and the environmental footprint requires fundamental changes in business and design logic.

Results from their research suggest that an approach and methods for Future Adaptive Design can enable companies to explore future uncertainties by identifying risks for premature obsolescence and associated cost drivers. Moreover, it can aid exploration of opportunities to redesign product architecture and components to increase the potential to significantly reduce business risks as well as the environmental load.

***Thomas Nyström*** Lic. Phil has more than 20 years of experience in circular design, business development, and organizational change management. In 2013 Thomas was part of starting up RISE research team Sustainable Business, that since, systematically has contributed to knowledge building around circular business models built on value preservation, with a potential to radically reduce climate/environmental impact.

Thomas's main research focus is on how physical products can be designed for reduced business risk in circular business models. This could be achieved by designing physical products for extended functional life through Future Adaptive Design which could mitigate the risk of premature obsolescence. Thomas has a background as an industrial designer and has the privilege of doing just that, contributing to designing industries to better fit in a circular economy.

***Anneli Selvefors*** is a design researcher and innovation catalyst at RISE - the Research Institutes of Sweden. Her research focuses on how companies can rethink their design and innovation processes and develop sustainable and circular offers. Primarily, she explores opportunities to design for circular business models, to facilitate circular consumption, and to enable sustainable lifestyles. An important part of her work is to develop, assess, and disseminate new methods and tools for sustainable design and business model innovation.

Since 2019, Anneli is a member of the reference group for the Swedish Delegation for Circular Economy and has been the chair of one of its expert groups tasked with proposing new policies and other measures that can aid Swedish companies to design for circularity. During 2020-2022 she was also a member of one of the working groups of the Swedish Government's innovation partnership programme Climate Neutral Industry that advised the Government on how circular design can aid development of sustainable innovations. She holds a Ph.D. in Human-Technology-Design and a M.Sc. in Industrial Design Engineering from Chalmers University of Technology.

Susanna Horn:

## Ecodesign for Sustainable Products Regulation (ESPR)

The recent proposal for Ecodesign for Sustainable Products Regulation (ESPR) aims to reduce the negative life cycle environmental impacts of products and improve the functioning of the market. It is strongly linked to its predecessors, the Ecodesign directives but extends the existing framework to cover a very broad range of products (such as textiles) and widens the scope of the requirements with which products are to comply. The new Ecodesign regulation is also linked to multiple other EU policy frameworks, such as the EU Green Deal, EU Industrial policies, the Circular Economy Action Plan, the EU textile strategy as well as initiatives related to sustainable production and consumption and waste management. The actions proposed in the new ESPR cover, for instance, binding requirements for the environmental sustainability of textile products, such as longevity, repairability and recyclability requirements; the implementation of a digital product passport for textile products; mandatory requirements concerning public procurement; and banning the destruction of unsold and/or returned textiles.

Continues on the next page »

The implementation of the regulation will cause some changes to the way stakeholders are operating and prepare them to transition to sustainable and circular economy. Nevertheless, it raises several concerns by the private actors due to the regulation being mandatory and binding for all member states. The keynote will discuss these changes, concerns and implications to various stakeholders, the status of the regulation, and the potential drawbacks that still remain. In addition, the possibility to lay down specific minimum standards for placing different products on the market will be discussed from the viewpoint of product-specific ecodesign requirements. Due to the regulation being still in preparation, the contents of this keynote will be subject to updates according to the progress of the preparation.

***Susanna Horn***, DSc (Econ). Group manager in the Industry and value chains the Finnish Environment Institute (Syke). Susanna is currently working in projects related to circular economy and life cycle approaches related to textiles, plastics, digitalization, metals, as well as ecodesign, innovation, policies and data questions. Her main expertise is in the strategic use of life cycle methods. Prior to working in Syke, she has worked in the metals and mining sector in sustainability and innovation positions, as well as in the university sector as a researcher. PhD in business-related application of LCA methodologies, Master's degrees in Economics (JYU) and Sustainable Resource Management (TUM).

---

***Paula Sarsama*** is Infinited Fiber Company's Program Manager, a circular economy enthusiast with passion for finding solutions to decrease the environmental impact of the fashion industry. Her focus is on creating collaborations with other stakeholders in the circular value chain and ecosystem, with an aim of making circularity in textiles an everyday reality. Prior to joining Infinited Fiber Company, she was a Senior Scientist at VTT, leading several projects in the areas of sustainability and bio-based materials. Paula has over 20 years' experience in leading commercial and technology projects in industry, business, and academia.

**Learn more about Infinited Fiber Company at**
www.infinitedfiber.com

***Nina Teufel*** is an experienced Innovation Manager with a strong background in the sports apparel industry. With a passion for driving conceptual innovation and creating sustainable solutions, Nina has been actively involved in various roles related to sports apparel Innovation, development and purchasing for companies as adidas and H&M. Since February 2021, Nina has been leading the conceptual side for adidas of the PFRP (Publicly Funded research project) New Cotton New Cotton Project. An Industry consortium of 12 pioneering partners driving circularity forward. In that role she has been instrumental in creating a vision for new cellulosic materials, aiming to introduce sustainable and circular alternatives in the apparel industry. Within that project, adidas by Stella McCartney has launched a capsule collection in FW22 to demonstrate a circular approach. As part of the Innovation Concepts team, Nina has also been driving strategic innovation projects related to several sports, always pushing the limits of performance and sustainability.

5th PLATE 2023 Conference
Espoo, Finland - 31 May - 2 June 2023

# Co-creating a Vision for the Circular Economy: A Case Study of the Polyurethane Foam Industry via Backcasting

**Mona Abadian[a], Jennifer D Russell[a]**
a) Virginia Tech, Blacksburg, United States

**Keywords**: Circular economy; Backcasting; Polyurethane foam; End-of-life management; Recycling, Sustainability; Transition strategy.

**Abstract**: The circular economy (CE) is seen as a way to address the environmental impact of plastic waste. Achieving a CE requires advanced technical solutions, innovation, and reconfiguring the value-chain and stakeholder practices. Backcasting is a method of strategic planning, commonly used for policy development, that involves integrating different perspectives from stakeholders, starting with a co-created vision. A two-day workshop was held using backcasting to explore opportunities and strategies for a CE transition within the polyurethane (PU) foam product value-chain. Participants from industry, government, and academia were tasked with clarifying an ideal CE future state for diverse PU foam stakeholders and to identify gaps in the current system. Participants developed, discussed, and ranked priorities for stakeholders in each part of the value-chain and find consensus strategies for transitioning. During the workshop, 348 ideas were generated, and stakeholders agreed to develop a common vision for CE within the industry. From these, participant groups identified strategic priorities for CE advancement, including customers, manufacturers, producers, distributors, retailers, recyclers and recovery, suppliers to manufacturers, and research. By utilizing the backcasting methodology, industry stakeholders engaged in collaborative efforts and open discussions, leading to a mutual comprehension of the requisite infrastructure for the transition towards a circular economy. The outcomes of the study offer valuable perspectives into potential pathways for achieving a circular economy in the PU foam industry.

## Introduction

Environmental impacts have incrementally increased pressure on industrial businesses (Lieder & Rashid, 2016). The circular economy (CE) has been proposed as a solution to mitigate the environmental impacts of plastic consumption and waste disposal. The CE concept has attracted significant attention from both academics and professionals, as it is viewed as a way for businesses to practice sustainable development (Geisendorf & Pietrulla, 2018; Ghisellini et al., 2016). However, implementing the CE concept is not a straightforward process, and it requires innovative actors who can provide services and designs towards appropriate radical changes in practices, policies, and decision-making tools (Golinska et al., 2015; Murray et al., 2017). Furthermore, CE demands advanced technical solutions (MacArthur, 2013), such as depolymerization, alongside innovation and reconfiguring the value chain and stakeholder practices. Industry stakeholders are keen on adopting a CE model within their respective value chains, as they possess the requisite competencies, resources, and capabilities to drive the necessary transformations. Their active participation is vital for the successful implementation of the CE (Gallego-Schmid et al., 2019). Innovative technologies are being developed to convert end-of-life products into useful feedstocks for production processes. However, the implementation of effective and feasible systems is crucial for the successful diversion, collection, capture, and reintegration of materials, which are widely distributed across millions of sites. Therefore, it is essential to develop comprehensive strategies that address the challenges associated with material recovery and recycling. To bridge the gap between the technology developed and the current product cycling system assessment, an evaluation of the market potential and feasibility of select pivoting technologies will be conducted through backcasting. Backcasting is an approach that aims to foster a participatory and collaborative process among stakeholders by establishing a common vision and purpose for the future. Stakeholders to the system are engaged to identify and reverse-engineer key focus areas, innovations, and interventions to expedite the transition to more efficient and effective systems (Gaziulusoy & Erdoğan Öztekin, 2019; Watz & Hallstedt, 2020). The ABCD-procedure are used in accordance with the funnel metaphor presented in the Framework for Strategic Sustainable Development (Broman & Robèrt, 2017) to establish a common terminology and co-create a future vision for circularity.

In this study the backcasting method was employed in a case study centered around the polyurethane (PU) foam value-chain to investigate the potential opportunities and strategies for transitioning to a CE for relevant PU foam products, including mattresses, furniture, and insulation. PU foam is the sixth most used polymer in the US and is highly versatile is widely used in various applications, including the automotive industry, insulation, (Das & Mahanwar, 2020). However, with the increasing amount of PU foam waste generated and disposed each year, there is a growing focus on CE solutions to close these material loops (Kraitape & Thongpin, 2016). Recycling PU foam is challenging due to its resistance to degradation, making it difficult to dispose of at end-of-life (EOL), This study aims to identify new opportunities and effective strategies for a smoother transition towards a CE in this industry. By exploring avenues for innovation and development, we can address challenges and barriers towards a more sustainable future. With a collaborative approach and leveraging the latest research, this study provides practical insights for informed decision-making and effective solutions.

## Methodology

The study uses the ABCD backcasting methodology (Broman & Robèrt, 2017): Awareness and defining success (A), Baselining the current state (B), Creative solutions (C), and Decide on priorities (D). During the workshop, participants inductively worked through the four scaffolded A-B-C-D activities. The workshop hosted 43 workshop participants (in-person and virtually) representing PU foam stakeholders, including recyclers (4.7%), chemical suppliers (39.5%), manufacturers of PU foam /products (23.3%), academia (25.6%), and governments (6.9%). Online participants were included through the use of Zoom's collaborative online room option, and the digital collaboration whiteboard tool was used to share ideas for both in-person and virtual formats.

At the outset of the workshop, the participants were guided through the first two stages of the ABCD backcasting methodology (Steps A and B). Workshop participants independently worked to identify the essential needs and requirements of a successfully implemented circular economy in the PU foam value chain (hereafter referred to as "CE requirements") based on different positions within the value chain. These questions focused on identifying stakeholders, potential opportunities, and barriers associated with implementing CE initiatives in the PU foam industry. During Steps C & D of the workshop, participants were asked to share their solutions and CE requirements for a sustainable future in the industry. The participants were divided into eight pre-assigned groups, comprising individuals from different parts of the value chain / lifecycle stages: (1) chemical suppliers, (2) manufacturers, (3) distributors and retailers, (4) consumers, and (5) recyclers (6) governments and policy makers and (7) academia (hereafter referred to as "value chain stakeholder groups"). Groups were then tasked with collaboratively developing an ideal vision of a future CE for each stakeholder group. A total of six scenarios were presented for groups to consider where the PU foam industry had achieved circularity, i.e., "*Imagine: We have a magic wand - and now the polyurethane foam industry is 100% circular. Describe what this looks like for [e.g., consumers]*?" Five scenarios focused on each stakeholder group, and a sixth scenario asked participants to consider policy and research needs and priorities. Groups rotated across topics at least three times to ensure diverse perspectives and contributions, and to generate a range of innovative solutions and priorities.

The research team organized the resulting CE innovation ideas into different categories based on the common themes that emerged, hereafter referred to as "CE pathways." To determine priorities in Step D, participants were then instructed to personally identify and rank their top five CE pathways for each value chain category from the list generated in Step C. A five-point Likert-type scale was used, in which 1st rank was assigned for the "Most Important" pathway, and received 5-points, and 5th rank was assigned for "Least Important" and received 1-point. To facilitate this, an online survey was distributed to each participant, containing all the visions in each category, and requesting them to rank them from first to fifth priority. Finally, participants were formed into diverse groups and given the task of collaboratively identifying their top three priority visions (unranked) from the same list of CE visions used for individual prioritization.

## Results and Discussion

Data collected during Steps A and B of the backcasting method revealed general alignment of participants regarding the current conditions that may enable the transition to CE for PU foam products. Despite general agreement about CE opportunities, i.e., consumer interest and willingness to engage in CE, a total of 84 barriers to a CE transition for the PU foam industry were also identified (Figure 1). The most significant concerns, representing 47.6%, were related to technological barriers (e.g., materials and product design constraints). This was followed by infrastructure-related barriers (e.g., reverse-logistics and the cost of scaled recycling) at 17.9%, market barriers (e.g., the low cost of primary feedstock, lack of standardization, and low ROI expectations) at 14.3%, and regulatory barriers (e.g., lack of policies to align value chain actors) at 9.5% (Figure 2).

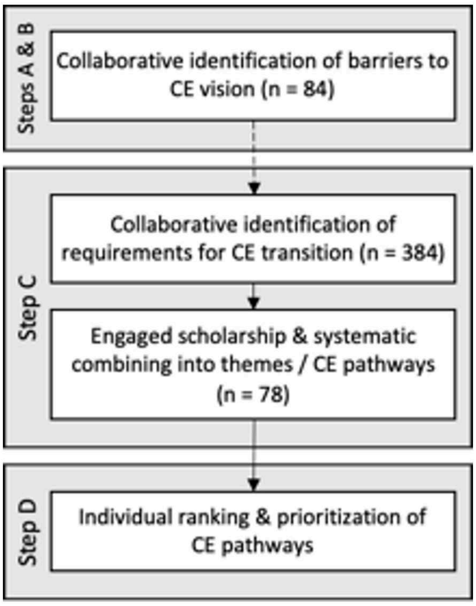

**Figure 1. Primary activities and outputs of backcasting method used in the workshop.**

Data collected during Step C of the backcasting methodology generated a total of 348 CE requirements that were identified and assigned by workshop participants to the value chain stakeholder group perceived to be the most likely/able to implement the CE requirement (Table 1). The greatest shares of CE requirements were identified for PU foam manufacturers (18.1%), and for chemical suppliers (18.1%). However, all value chain stakeholders were identified as having critical CE requirement responsibilities, with consumers and recycling agents assigned 16.7%, respectively, distributor/retailers assigned 14.1%, and action by policy makers, researchers, and investment accounting for 16.3%. Further inductive analysis by the research team integrated elements of engaged scholarship (Bansal & Corley, 2011) and systematic combining (Dubois & Gadde, 2002), and resulted in the emergence of 78 CE pathways into which the 348 CE requirements were organized (Table 1).

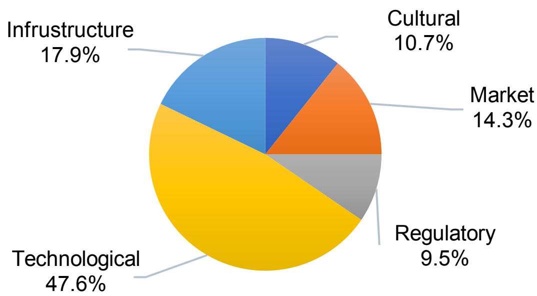

**Figure 2. Categorization of the barriers to CE transition for the PUF value chain, as identified by workshop participants.**

| Value chain stakeholder groups | CE requirements | | CE pathways | |
|---|---|---|---|---|
| | (#) | (%) | (#) | (%) |
| Chemical suppliers | 63 | 18.1 | 11 | 14.1 |
| Manufacturers | 63 | 18.1 | 13 | 16.7 |
| Distributors and retailers | 49 | 14.1 | 10 | 12.8 |
| Consumer/Customers | 58 | 16.7 | 11 | 14.1 |
| Recyclers | 58 | 16.7 | 13 | 16.7 |
| Policies/ Research/ Investment | 57 | 16.3 | 20 | 25.6 |
| Total | 348 | 100 | 78 | 100 |

**Table 1. Distribution of CE requirements and CE pathways.**

For the purposes of this analysis, we focus on the pathways identified for *a select example of* PU foam value chain stakeholders: chemical suppliers, manufacturers, and recyclers.

Primary CE pathways identified for these stakeholder groups are presented in Table 2 (manufacturers), Table 3 (consumers and customer), and Table 4 (recyclers), along with the CE requirements that were combined to develop the CE pathway (Figure 1). The calculated "priority score" for each CE pathway is also presented in Table 2, and represents the total scores assigned through individual ranking.

As shown in Table 2, the data from the survey indicates that coordination with suppliers to establish clear circular material specifications/requirements (M4) is the most highly ranked priority in the value chain category. The development and implementation of material design requirements for circularity (M6) is the second highest priority, but the degree of consensus among the participants is lower (Table 2). There is indication of both need and desire for better alignment between manufacturers and their suppliers to enhance the circularity and sustainability of the PU foam value chain. In the case of recovery and recycling stakeholders (Table 3), establishing local collection infrastructure and consolidation points and coordinating with other stakeholders to effectively communicate and educate about local end-of-life options (RR4) emerged as the most critical factor for attaining circular economy, garnering 50% of the respondents' preference. Meanwhile, the stakeholders exhibited a degree of variability in ranking coordination with manufacturers and material suppliers to clarify the most important labeling requirements (RR7) and market development for by-products of chemical recycling (RR1) as their second and third priorities, respectively.

| **CE Pathways (Manufacturers)** | | **Priority score (Ind.)** |
|---|---|---|
| **Coding** | **Pathway** | |
| M4* | Coordinate with suppliers to establish clear circular material specifications/requirements | 43 |
| M6* | Develop and implement material design requirements for circularity (e.g., design to degrade; controlled degradation; substance/material separation) | 36 |
| M5* | Simplify material formulations to make end-of-use and end-of-life management and recycling easier and less costly | 32 |
| M9 | Collaborate with and grow upstream supply chain to increase circularity opportunities and compatibility of inputs (e.g., new sources, new feedstocks) | 28 |
| M10 | Collaborate with and grow downstream supply chain to facility circularity opportunities (e.g., streamlined recovery channels, purification, and secondary refining of recycled feedstocks; removal of harmful substances) | 28 |
| M7 | Develop and implement design requirements for product circularity (e.g., design for disassembly; design for durability; design for environment) | 26 |
| M3* | Clear product labeling and/or product identification (e.g., digital passport technology) regarding material composition and source information | 25 |
| M8 | Develop and implement product-appropriate recovery and circularity systems | 23 |
| M11 | Manufacturer leadership to design and manage collection systems for end-of-use/end-of-life products | 22 |
| M2 | Communicate with and manage customer/user expectations regarding the circular product (e.g., performance, color, longevity) | 12 |
| M12 | Sustainable facility transitions to renewable energy and energy efficient infrastructure and equipment | 11 |
| M1 | Pre-consumer (production) scrap recovery and cycling (not down-cycling or downgrading) | 8 |
| M13 | Growth and innovation of niche value-add activities needed for circular systems | 6 |

**Table 2. CE pathway priorities for PU foam manufacturers, as identified and ranked by individual participants and presented in order from highest to lowest. * denotes CE pathways collaboratively prioritized by groups (refer to Table 4).**

| CE Pathways (Recyclers) | | Priority score (Ind.) |
|---|---|---|
| **Coding** | **Pathway** | |
| RR4 | Establish local collection infrastructure and consolidation points and coordinate with other stakeholders to effectively communicate and educate about local end-of-life options | 47 |
| RR7 | Coordinate with manufacturers and material suppliers to clarify the most important labeling requirements needed for disassembly, recycling, and other end-of-life management options. | 35 |
| RR1 | Market development for by-products of chemical recycling (e.g., urea, primary amines, isocyanates) | 34 |
| RR5 | Streamline/optimize networks for pre-treatment, collection, and transportation of end-of-life products for recycling. | 30 |
| RR2 | Market development for by-products/outputs of mechanical recycling | 27 |
| RR3 | Establish dedicated 'pure' collection streams (e.g., hotels, universities, pre-consumer/production scrap) that can reduce loss/contamination in the system | 27 |
| RR6 | Develop and communicate a portfolio of circular economy options, including mechanical and chemical recycling, and reuse. | 27 |
| RR8 | Ensure broad-scale accessibility and convenience of collection points for customers/users | 26 |
| RR11 | Educate customers/users about the options that are available for circular economy, and the performance implications | 15 |
| RR12 | Educate customers/users about how to recycle their products, and how recycling is performed | 9 |
| RR13 | Innovate within the transportation system, e.g., electrification of fleets | 6 |
| RR9 | Educate customers/users about the structure and properties of the recycled materials | 3 |
| RR10 | Educate customers/users about the processes used to recycle | 2 |

**Table 3. CE pathway priorities for PU foam recyclers, as identified and ranked by individual participants and presented in order from highest to lowest.**

Collaborative group prioritization in the case of manufacturers (Table 4) revealed some level of coherence between individual viewpoints and the collective priorities of the different groups. Furthermore, the group discussion process was shown to be influential in shaping individual perspectives and promoting collaborative ideation towards prioritization. For example, in the Manufacturers' category, coordinating with suppliers to establish clear circular material specifications (M4) and simplifying material formulations to facilitate end-of-use and EOL management and recycling (M5) are deemed top priorities by both groups and individuals to achieve CE. In contrast, developing and implementing material design requirements for circularity (M6) was not a priority for the group (Table 4). Conversely, after group discussions, most stakeholders agreed that clear product labeling and/or product identification (e.g., digital passport technology) regarding material composition and source information (M3) would be more effective compared to developing and implementing material design requirements for circularity (e.g., design to degrade; controlled degradation; substance/material separation) (M6). This also suggests that diverse group discussions can offer greater clarity on the topic and help prioritize strategic pathways based on what is truly feasible and achievable.

| Value-chain Stakeholder Groups | Strategic Priorities | | | | | |
|---|---|---|---|---|---|---|
| | Group | | | Individuals | | |
| Producers/ Manufacturers | M3 | M4 | M5 | M4 | M5 | M6 |

**Table 4. comparison of prioritized pathways from individuals and groups' perspectives.**

## Conclusions

The interactive and diverse format of the workshop provided an opportunity for participants to gain a better understanding of diverse stakeholder priorities, concerns, and constraints. Through facilitated and structured discussion enabled by the backcasting methodology, industry stakeholders reached an improved understanding of the challenges, opportunities, constraints, and areas of innovation presented by the transition to CE. Moreover, through this collaborative process, multiple diverse strategic pathways and priorities were identified as part of a co-created and cohesive transition towards a CE. The study's findings provide valuable insights into potential pathways for the transition towards a CE in the PU foam industry, and demonstate the potential application of backcasting as a facilitation tool for industry.

f) Yonsei University, Seoul, South Korea
g) Kirinyaga University, Kerugoya, Kenya

**Keywords**: Circular economy; Interpretive structural modelling; Scaling up; Sustainable business; Upcycling.

**Abstract**: Upcycling is one promising approach to extending the lifetimes of products, components, and materials by utilising a variety of material processes and innovations to turn waste products and materials into products of higher quality or value than the compositional elements. Upcycling increases resource efficiency and reduces solid waste and industrial energy consumption. It creates new job opportunities for businesses and reduces costs for materials. Despite such benefits, however, upcycling remains a niche practice. Moving from a niche to a mainstream practice (or scaling-up) could realise the full potential of upcycling. Understanding interrelated and self-reinforcing challenges in the global upcycling value chain is critical for scaling up global upcycling businesses. As existing studies of upcycling are mostly industry and country-specific, the factors impacting upcycling success across industries and countries still need to be discovered, making it difficult to establish which challenges can be prioritised in effectively scaling up upcycling businesses internationally. This study aimed to identify critical global challenges and opportunities for scaling up upcycling businesses worldwide. We organised two online workshops with nine international experts in upcycling, utilising Interpretive Structural Modelling (ISM). The preliminary analysis of the ISM workshop results showed that all global challenges and opportunities are interlinked and that key opportunities reflect key challenges, with the first priority intervention suggested as 'involving citizens in upcycling initiatives or events' followed by 'improving material provision'.

## Introduction

Upcycling is one of the promising approaches to extending the life span of products, components and materials by utilising various material processes and innovations to transform used or waste products, components and materials into a product/material of higher quality or value than the compositional elements (Sung, 2017). Examples include 'creative' or 'advanced' forms of repair, reuse, repurpose, refurbishment, upgrade, redesign, remake, remanufacture, and recycling – within the remit of the circular economy, an alternative to the traditional linear economy of take, make use, and dispose (Stahel, 2016). The extended life span of used/waste products, components and materials by upcycling increases resource efficiency and reduces solid waste and industrial energy consumption in processing and manufacturing with virgin materials. Upcycling also creates new job opportunities for businesses and reduces material costs. Despite such benefits, however, upcycling remains a niche practice (Sung, Singh, & Bridgens, 2021). Moving from a niche to a mainstream practice or scaling up could lead to the full potential of upcycling. Understanding interrelated and self-reinforcing challenges in the global upcycling value chain are critical for scaling up global upcycling businesses. For example, consumers' negative perception of upcycled products affects the demand, which affects the price, and, therefore, sales, leading to a limited market resulting in few available good quality products that feedback into consumers' adverse perception of upcycled goods in fashion and furniture sectors (Singh, Sung, Cooper, West, & Mont, 2019). Existing studies of upcycling are mostly industry and country-specific (e.g., Cumming, 2017; Paras & Curteza, 2018; Singh et al., 2019). The factors impacting upcycling success across industries and countries are largely unknown, making it difficult to establish which challenges can be prioritised in effectively scaling up upcycling businesses internationally.

This study aimed to identify critical global challenges and opportunities for scaling up upcycling businesses worldwide. We initially conducted a literature review to identify global challenges and opportunities for scaling up upcycling. We used online questionnaires to narrow down the factors into six. We then held two online expert workshops to prioritise the factors, which are explained in more detail in the following section.

## Methods

### *Literature review*

The initial literature review to identify global challenges and opportunities for scaling up upcycling was conducted between February and March 2021, resulting in nine common categories of challenges and ten common opportunities for successful upcycling across industries and countries. Please find the details in the review paper published as a book chapter (Sung & Abuzeinab, 2021).

### *Online questionnaire*

We created an online questionnaire from the literature review to ask the study participants to select up to six key global challenges and opportunities for scaling up upcycling businesses. The answer options provided for global challenges were: (i) difficulty in sourcing materials, (ii) limitations from the materials (e.g. inconsistency, damage), (iii) lack of facilities or equipment, (iv) time-consuming processes, (v) limited knowledge and skills, (vi) limited good quality products, (vii) high sale price, (viii) difficult and expensive promotion/marketing activities, (ix) limited, affordable space, (x) financial constraints, (xi) limited legislation, standards, and warranty, (xii) consumers' negative perception of upcycled products, (xiii) consumers' low awareness of upcycling, and (xiv) other.

The answer options for global opportunities were: (i) improved material provision, (ii) suitable technologies, techniques, and innovation in production, (iii) targeting high-opportunity product categories, (iv) effective marketing, (v) support for the better mobilisation of resources and knowledge, (vi) financial support and incentives, (vii) varied stakeholder involvement (e.g., large brands, local authorities), (viii) awareness-raising training and education for consumers, (ix) involving citizens in upcycling initiatives or events, (x) awareness-raising campaign and communication, and (xi) other.

The online questionnaire was sent to 21 people interested in participating in the study within the International Upcycling Research Network funded by UKRI (UK Research and Innovation) AHRC (Arts and Humanities Research Council). Out of 21 people, 14 responses (67% response rate) were collected between July and August 2022. The respondents were nine academics and five practitioners with expertise in upcycling from 12 countries in five continents (Africa, Asia, Australia, Europe, and South America). The results showed that the majority of global upcycling experts (minimum 50%) agreed with six key global challenges and opportunities for scaling up upcycling businesses (Table 1).

| **Key global challenges** |
|---|
| C1. Limitations from the materials (e.g., inconsistency, damage) |
| C2. Lack of facilities/equipment |
| C3. Time-consuming processes |
| C4. Consumers' low awareness of upcycling |
| C5. Consumers' negative perception of upcycled products |
| C6. Limited legislation, standards, and warranty |
| **Key global opportunities** |
| O1. Improved material provision |
| O2. Targeting high-opportunity product categories |
| O3. Suitable technologies, techniques, and innovation in production |
| O4. Varied stakeholder involvement (e.g., large brands, local authorities) |
| O5. Involving citizens in upcycling initiatives/events |
| O6. Awareness-raising activities (e.g., campaign, communication, training, education) |

**Table 1. Key global challenges and opportunities for scaling up upcycling businesses.**

*Interpretive Structural Modelling online workshops*

Using the online questionnaire results (Table 1), we prepared for the Interpretive Structural Modelling (ISM) online workshops. ISM is a qualitative and interpretive method used to structure various factors into a hierarchy based on the importance of the factors and visualise the interaction between these factors to help decision-makers in tackling these factors in order (Abuzeinab, Arif & Qadri, 2017; Attri, Dev & Sharma, 2013). Two online workshops were organised in September 2022. The workshop invitation was sent to the same 21 AHRC-funded International Upcycling Research Network members who expressed their interest in the study participation (who also received the online questionnaire). Nine international experts in upcycling participated in the workshops. They were academics and practitioners from seven countries (Botswana, Kenya, India, Nigeria, South Africa, South Korea, and the UK) covering three continents (Africa, Asia and Europe).

At the beginning of the workshop, the facilitator explained the aim and objectives of the workshop and procedures. The main workshop was organised in such a way that the facilitator presented each factor (challenge or opportunity) with other factors, and asked the participants whether the presented factor would influence other factors. Individual opinions were collected, and group agreement was sought. For data collection, notes were taken on the main points and agreement, and the workshops were video recorded with the participants' consent. The data were analysed by developing SSIM (Structural Similarity Index) and RM (Reachability Matrix), and MICMAC (cross-impact matrix multiplication applied to classification) analysis (Nilashi, Dalvi, Ibrahim, Zamani & Ramayah, 2019).

## Results

*Key global challenges*

Four symbols were used to denote the direction of the relationship between any two global challenges (i and j):

- V: challenge i will influence challenge j, but not in both directions.
- A: challenge j will influence challenge i, but not in both directions.
- X: challenge i and j will influence each other.
- O: challenge i and j are unrelated.

See Table 2 for the SSIM (Structural Similarity Index) and Table 1 for C1 to C6 descriptions.

| | C1 | C2 | C3 | C4 | C5 | C6 |
|---|---|---|---|---|---|---|
| **C1** | | X | X | A | A | X |
| **C2** | | | X | A | X | X |
| **C3** | | | | X | V | X |
| **C4** | | | | | X | X |
| **C5** | | | | | | X |
| **C6** | | | | | | |

**Table 2. SSIM for global challenges.**

The RM (Reachability Matrix) was obtained by converting the SSIM into a binary matrix by substituting V, A, X, and O with 1 and 0 as per the case. The rules for the substitution of 1s and 0s are the following:

- if the (i, j) entry in the SSIM is V, then the (i, j) entry in the reachability matrix becomes 1, and the (j, i) entry becomes 0.
- if the (i, j) entry in the SSIM is A, then the (i, j) entry in the reachability matrix becomes 0, and the (j, i) entry becomes 1.
- if the (i, j) entry in the SSIM is X, then the (i, j) entry in the reachability matrix becomes 1, and the (j, i) entry also becomes 1.
- if the (i, j) entry in the SSIM is O, then the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0.

Driving power and dependence scores are the sums in rows and columns (Table 3).

| | C1 | C2 | C3 | C4 | C5 | C6 | Driving power |
|---|---|---|---|---|---|---|---|
| **C1** | 1 | 1 | 1 | 0 | 0 | 1 | 4 |
| **C2** | 1 | 1 | 1 | 0 | 1 | 1 | 5 |
| **C3** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **C4** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **C5** | 1 | 1 | 0 | 1 | 1 | 1 | 5 |
| **C6** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **Dependence** | 6 | 6 | 5 | 4 | 5 | 6 | 32/32 |

**Table 3. RM matrix for global challenges.**

Based on the RM matrix, MICMAC analysis classified global challenges as seen in Figure 1. The major findings of this classification are as follows:

- The diagram indicates that no challenge comes under an autonomous cluster. Autonomous challenges generally appear as weak drivers, weakly dependent and relatively disconnected from the system. These challenges have little influence on other challenges of the system.
- There are also no dependent challenges. The dependent challenges mean other

challenges need to be addressed and removed before their removal.

- There were also no challenges within the driver cluster. Driver challenges will have strong driving power but weak dependence power. Driver challenges need to be addressed first and they can influence all other challenges.
- All challenges are within the linkage cluster. Linkage challenges have a strong driving power as well as strong dependence. These challenges are unstable because any action on them will affect others and have a feedback effect on themselves.

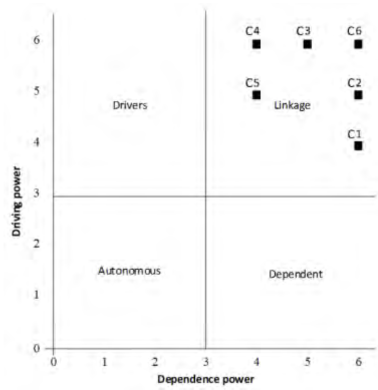

**Figure 1. MICMAC analysis for global challenges.**

Table 4 shows the partitioning of the RM into different levels (iterations 1 to 3).

| Challenge | Reachability set | Antecedent set intersect | Intersection set | Level |
|---|---|---|---|---|
| **Iteration 1** | | | | |
| **C1** | C1,2,3,6 | C1,2,3,4,5,6 | C1,2,3,6 | 1st |
| **C2** | C2,1,3,5,6 | C2,1,3,4,5,6 | C2,1,3,5,6 | 1st |
| **C3** | C3,1,2,4,5,6 | C3,1,2,4,6 | C3,1,2,4,6 | |
| **C4** | C4,1,2,3,5,6 | C4,3,5,6 | C4,3,5,6 | |
| **C5** | C5,1,2,4,6 | C5,2,3,4,6 | C5,2,4,6 | |
| **C6** | C6,1,2,3,4,5 | C6,1,2,3,4,5 | C6,1,2,3,4,5 | 1st |
| **Iteration 2** | | | | |
| **C3** | C3,4,5 | C3,4 | C3,4 | |
| **C4** | C4,1,5 | C4,3,5 | C4,5 | |
| **C5** | C5,4 | C5,3,4 | C5,4 | 2nd |
| **Iteration 3** | | | | |
| **C3** | C3,4 | C3,4 | C3,4 | 3rd |
| **C4** | C4,1 | C4,3 | C4 | |

**Table 4. RM into levels for global challenges.**

From the analyses including the levels determined, the ISM model was developed for global challenges (Figure 2). The model shows that all the challenges are interlinked – arrow directions denoted the relationship. The model was structured on four levels. At the base of the structure, 'consumers' low awareness of upcycling' will need to be addressed before moving up to level 3 (C3: 'time-consuming processes') and level 2 (C5: 'consumers' negative perception of upcycled products'). Three challenges at the top of the structure (C1: 'limitations from the materials', C2: 'lack of facilities/equipment', and C6: 'limited legislation, standards, and warranty') can be addressed at the end.

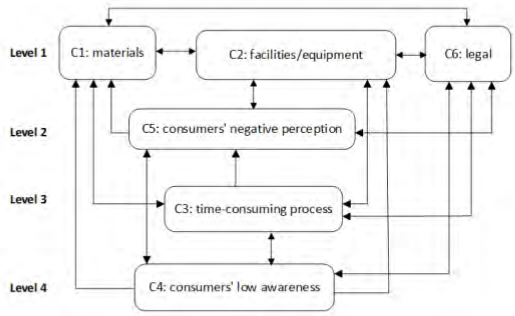

**Figure 2. ISM model for global challenges.**

*Key global opportunities*

SSIM for global opportunities was developed using the same approach for global challenges (Table 5). See Table 1 for O1 to O6 descriptions. Then, the RM was obtained using the same approach for global challenges (Table 6).

| | O1 | O2 | O3 | O4 | O5 | O6 |
|---|---|---|---|---|---|---|
| **O1** | | V | X | X | X | X |
| **O2** | | | X | X | X | A |
| **O3** | | | | X | A | A |
| **O4** | | | | | X | X |
| **O5** | | | | | | X |
| **O6** | | | | | | |

**Table 5. SSIM for global opportunities.**

| | O1 | O2 | O3 | O4 | O5 | O6 | Driving power |
|---|---|---|---|---|---|---|---|
| **O1** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **O2** | 0 | 1 | 1 | 1 | 1 | 0 | 4 |
| **O3** | 1 | 1 | 1 | 1 | 0 | 0 | 4 |
| **O4** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **O5** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **O6** | 1 | 1 | 1 | 1 | 1 | 1 | 6 |
| **Dependence** | 5 | 6 | 6 | 6 | 5 | 4 | 32/32 |

**Table 6. RM matrix for global opportunities.**

MICMAC analysis based on the RM matrix classified global opportunities (Figure 3). There are no autonomous, dependent or driver opportunities; all the opportunities are within the linkage cluster (just like challenges), showing strong driving power as well as strong dependence.

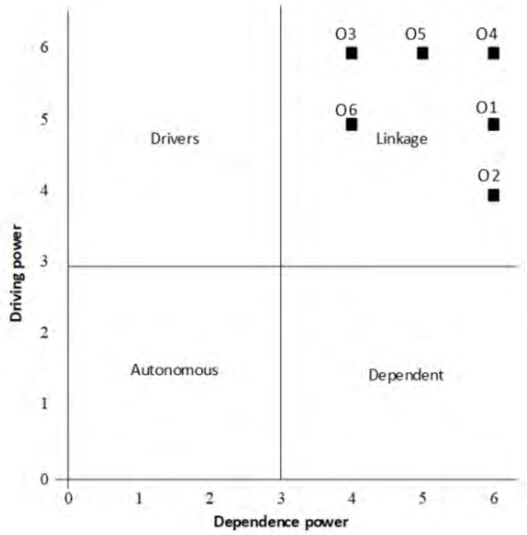

**Figure 3. MICMAC analysis for global opportunities.**

Table 7 shows the partitioning of the RM into different levels (iterations 1 and 2), from this, the ISM model was developed for global opportunities (Figure 4).

| Challenge | Reach-ability set | Antecedent set intersect | Inter-section set | Level |
|---|---|---|---|---|
| | | **Iteration 1** | | |
| **O1** | O1,2,3,4, 5,6 | O1,3,4,5,6 | O1,3,4,5, 6 | |
| **O2** | O2,3,4,5 | O2,1,3,4,5,6 | O2,3,4,5 | 1st |
| **O3** | O3,1,2,4 | O3,1,2,4,5,6 | O3,1,2,4 | 1st |
| **O4** | O4,1,2,3, 5,6 | O4,1,2,3,5,6 | O4,1,2,3, 5,6 | 1st |
| **O5** | O5,1,2,3, 4,6 | O5,2,4,6 | O5,2,4 | |
| **O6** | O6,1,2,3, 4,5 | O6,1,4,5 | O6,1,4,5 | |
| | | **Iteration 2** | | |
| **O1** | O1,5,6 | O1,5,6 | O1,5,6 | 2nd |
| **O5** | O5,1,6 | O5,6 | O5,6 | 3rd |
| **O6** | O6,1,5 | O6,1,5 | O6,1,5 | 2nd |

**Table 7. RM into levels for global opportunities.**

The model (Figure 4) shows that all the opportunities are interlinked (relationships indicated with the arrow directions). The model was structured on three levels. At the base of the structure, O5: 'involving citizens for upcycling initiatives/events' will need to be prioritised at the start before moving up to level 2 (O1: 'improved material provision' and O6: 'awareness-raising activities') and then level 1 (O2: 'targeting high-opportunity product categories', O3: 'suitable technologies, techniques, and innovation in production', O4: 'varied stakeholder involvement').

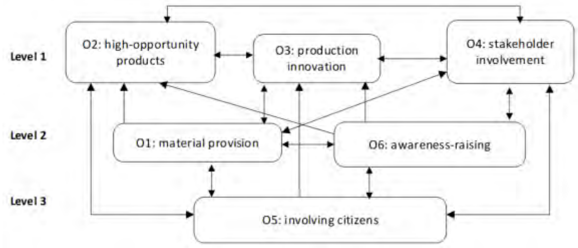

**Figure 4. ISM model for global opportunities.**

## Discussion and conclusions

The results showed that all key global challenges and opportunities are interlinked (within the category) and that key opportunities reflect key challenges. For example, the most important opportunity was 'involving citizens in upcycling initiatives/events' (Level 3 in Figure 4) when the most important challenge appeared to be 'consumers' low awareness of upcycling' (Level 4 in Figure 2). Although, this is still a preliminary analysis result based on the contributions by the nine international experts within the AHRC-funded International Upcycling Research Network. We are organising the third ISM workshop in person during the PLATE (Product Lifetimes And The Environment) Conference 2023. The third workshop involving other global experts in sustainable production and consumption (outside the network project) will validate these findings. As a limitation of this study, we are aware that the approach we used (bundling all data) does not necessarily reflect different contexts. Our approach also does not allow comparative analysis between different countries or continents. But the main point of this study is to identify the key global challenges and opportunities regardless of contextual differences.

Assuming that these results are more or less correct, the following practical implications could be derived. As both ISM models showed (Figures 2 and 4), the first priority action as an intervention for scaling up global upcycling businesses should be 'involving citizens in upcycling initiatives and events for awareness raising including campaign, communication, training and education' (Levels 2 and 3 in ISM model for global opportunities) in order to address 'consumers' low awareness of upcycling' and 'consumers' negative perception of upcycled products' (Levels 2 and 4 in ISM model for global challenges). The second priority interventions could be 'improving material provision' (Level 2 in Figure 4) and addressing 'time-consuming processes' (Level 3 in Figure 2) by 'suitable technologies, techniques, and innovation in production' (Level 1 in Figure 4).

## Acknowledgements

This work was supported by the AHRC Research Networking grant for International Upcycling Research Network [grant number AH/W007134/1] and the generous staff innovation allowance from De Montfort University (DMU). The DMU Faculty (Arts, Design and Humanities) Enhancing Research Culture fund also partially supported the conference attendance. We thank Guy Bingham, Stuart Lawson, Kelley Wilder, Kate Cheyne, Siobhan Keenan, Deborah Cartmell and Heather McLaughlin for supporting this research at DMU.

# Fostering product lifetime extension practices among young consumers: Implications for policymakers from a consumer behavior perspective

**Laura Ackermann**[a, b], **Dominik Walcher**[b], **Sybille Salbrechter**[b]
a) Centre for Sustainability Management, Leuphana University Lüneburg, Lüneburg, Germany
b) Design & Produktmanagement, Fachhochschule Salzburg GmbH, Puch/Urstein, Austria

**Keywords**: Repair; Maintenance; Interventions; Policymakers; Consumer behavior.

**Abstract**: Product care describes all activities conducted by consumers that extend product lifetimes and includes maintenance and repair practices as well as preventive measures. By now, instruments for policymakers to foster product care often do not consider the consumer perspective and are based on theoretical considerations. We explore product care among young consumers to get a deeper insight into consumers' current care behavior and to propose consumer-oriented interventions for policymakers based on these insights. An online survey with 771 participants was conducted in Austria. Our data reveals two distinct clusters of young consumers: Expressive Caregivers and Reserved Caresavers. Both groups do not only differ on their product care behavior but also on different values and behaviors related to the environment. In addition, we show that family members framing product care as something that should be plays an important role for young consumers. We propose interventions for policymakers that consider the two consumer clusters as well as further insights on the determinants of product care. By doing so, we expand the body of knowledge on policy interventions for product care by considering the consumer perspective on this issue.

## Introduction

Product care describes all consumer activities extending product lifetimes, including maintenance and repair practices as well as preventive measures (Ackermann et al., 2018). Product care keeps the product in a usable and appealing state for a longer time, thereby postponing its replacement by new products (van den Berge et al., 2021). Thus, product care supports the concept of the Circular Economy (Hobson et al., 2021).

Previous studies have investigated how consumers' willingness and ability to take care of products can be fostered. These approaches often addressed the design of products (e.g., Bocken et al., 2016; van Nes & Cramer, 2005), thereby focusing mainly on manufacturers' responsibility to offer products that consumers can easily take care of. Instruments for policymakers to extend the lifetimes of consumer durables include for example extended liability periods and consumer protection laws (see, e.g., Svensson-Hoglund et al., 2021). However, these approaches often do not consider the consumer perspective on product care and are based on theoretical considerations (see also Maitre-Ekern & Dalhammer, 2019). We argue that a deeper understanding of the mechanisms underlying current consumer behavior is necessary to develop appropriate policy instruments that do not only address manufacturers and suppliers but also consumers. Therefore, this study aimed to explore factors influencing product care among consumers to get a deeper insight into consumers' current care behavior and to propose consumer-oriented interventions for policymakers based on these insights.

Prior research has shown that opinion leadership plays is important for sustainable consumption (Jansson et al., 2017). Opinion leadership describes influencing "the opinions, attitudes, beliefs, motivations, and behaviors of others." (Valente & Pumpuang, 2007). An *opinion leader* is someone who is particularly interested in a specific field and frequently exchanges information about it with others (Lazarsfeld et al., 1944). Opinion leaders can act as role models for behavior change and should be addressed by specific

communication measures (Petruch & Walcher, 2021). We also
explored additional social aspects, such as the influence of family members and education, as well as other measures of sustainable consumption to derive a meaningful data base for our interventions.

## Study

An online survey with panel members of an international market research company was conducted and analyzed. The items from the original scales presented in the following section were translated into German for our survey. The sample consisted of 771 18- to 35-year-old people (μ = 26.8 years; σ = 5.1 years) living in Austria and was representative for Austria regarding gender (50% female, 49% male, 1% X), federal state, and educational background.

### *Method*

We selected coffee machines and bicycles as products of investigation because product care (e.g., decalcifying the coffee machine, lubricating the bike chain) does not require specific skills or knowledge and should thus be doable for everyone. To get a more general picture on product care, we combined the evaluations of both products. Since not all surveyed participants possess a coffee machine (73% possession), respectively a bicycle (83% possession), the number of usable answers decreased from 771 to 477.

Product care for coffee machine (Cronbach's α = 0.939) and product care for bicycle ( α = 0.935) were thus combined into one common factor *product care*. If not stated otherwise, all rating scales ranged from 1 = very low to 7 = very high or 1 = I totally disagree to 7 = I totally agree.

Product care was assessed based on the product care tendency scale (Ackermann et al., 2021; [product] was replaced by «coffee machine» or «bicycle», respectively):

- It is important for me to take care of my [product].
- I look after my [product].
- I try to prevent my [product] from damage.
- I clean my [product].
- I have the necessary equipment for care activities on my [product].
- I am experienced in looking after my [product].
- I can look after my [product] well.
- In general, looking after my [product] is a positive experience.
- Taking care of my [product] gives me a good feeling.
- It makes me proud that I am able to take care of my [product].

Specific reasons for taking care and for not taking care of products were assessed by asking "How important are the following reasons for you to (not) take care of your products (e.g., bicycle, coffee machine etc.)?", answers ranging from 1 = very important to 7 = not important at all. Possible answers for taking care were "because it is fun", "extending the lifetime of my products", "saving money for new products", "positive effect on the environment", "because I was educated that way". Given reasons for not taking care were "costs of spare parts and care products", "lack of time", "lack of motivation", "no relevance", "missing trust in myself to manage and complete this task", and "no equipment". We explored *green consumption values* (α = 0.911) using the six items of the GREEN scale (Haws et al., 2014), such as "It is important to me that the products I use do not harm the environment.". We used four items such as "I know how to behave sustainably." to assess *perceived environmental knowledge* (Rausch & Kopplin, 2021, α = 0.908). For *environmental concern* (Meyerding et al., 2019, α = 0.878), we used such items: "It bothers me that some people are so little interested in the environment.". *Direct environmental behaviors* was assessed with four items (Kilbourne & Pickett, 2008; α = 0.837; e.g., "I reduce household waste whenever possible."). We added four items about *indirect environmental behaviors* (Kilbourne & Pickett, 2008; α = 0.882). One item of this scale is "I am a member of an environmental organization.".

Several other drivers of product care were assessed with single-item questions. While multi-item measurements are often recommended (Churchill, 1979), single-item questions are a valid approach for concrete objects of interest (Bergkvist & Rossiter, 2007).

We thus assessed *perceived own competence* with the item "How would you rate your competence to maintain and repair your products (e.g., bicycle, coffee machine) yourself?", and *family behavior* by "My parents and family members maintain and repair their products (e.g., bicycle, coffee machine) themselves". Likewise, the *self-image* of Austria was assessed as a possible driver of product care using "People in Austria basically maintain and repair their products (e.g., bicycle, coffee machine etc.) themselves.". Finally, *opinion leadership* (α = 0.852) was captured with three items based on Childers (1986): "I often talk to friends and acquaintances about the topics of repair, maintenance, and care of products.", "When it comes to the topics of repair, maintenance, and care of products, I am often asked by friends and acquaintances for my opinion and advice." and "In discussions about repair, maintenance, and care of products, I can tell others more than they can tell me."

## *Findings*

First, we analyzed whether the respondents can be grouped into distinct segments according to their product care behavior. For this purpose, a two-step cluster analysis with product care as the first clustering dimension was executed. In analogy to Petruch and Walcher (2021), opinion leadership regarding product care was chosen as the second factor. Generally, a two-step cluster analysis aims to identify homogenous subgroups in the study population. This analysis is frequently used in market segmentation, where an inconsistent total market is subdivided into segments maximizing the in-group homogeneity and between-group heterogeneity (Hair et al., 2016).

Our two-step cluster analysis incorporating product care and opinion leadership as continuous variables using Log-Likelihood distance measurement and Schwarz's Bayesian Criterion revealed a two-cluster solution (see Fig. 1) showing the best model fit and cluster quality concerning silhouette measure for cohesion and separation (Georgii, 2009). A value of nearly 0.5 was obtained, representing good cluster quality (Kaufman & Rousseeuw, 2005). All 477 cases could be assigned to one of the two clusters. Based on the expression of their characteristics, these clusters were named *Expressive Caregivers* (*n* = 224; 46.9%) and *Reserved Caresavers* (*n* = 253; 53.1%). Expressive Caregivers show significantly increased product care behavior and communication about repair, maintenance and care compared to Reserved Caresavers.

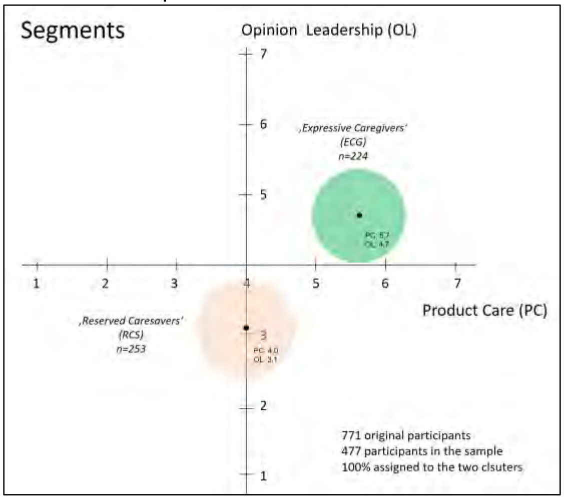

**Figure 1. Identified clusters.**

The Expressive Caregiver segment is significantly determined by male participants (62 %), whereas the proportion of women is higher in the Reserved Caresaver segment (55 %). There is no significant difference related to age. Moreover, Expressive Caregivers have significantly higher values for all possible drivers of product care than Reserved Caresavers, including self-image and family behavior (Table 1).

| | **Expressive Caregivers μ/σ** | **Reserved Caresavers μ/σ** | **Mean Comparison (t-test)** |
|---|---|---|---|
| *n* | 224 | 253 | |
| age | 27.2 / 4.8 | 26.9 / 5.3 | ns. |
| gender | 62 % male | 55 % female | $p^1 < .001$*** |
| product care | 5.7 / 0.6 | 4.0 / 0.8 | $p < 0.001$*** |
| opinion leadership | 4.7 / 1.1 | 3.1 / 1.3 | $p < 0.001$*** |
| green consumption values | 5.1 / 1.2 | 4.6 / 1.3 | $p < 0.001$*** |
| perceived environmental knowledge | 5.4 / 1.1 | 4.9 / 1.2 | $p < 0.001$*** |
| environmental concern | 5.1 / 1.2 | 4.7 / 1.4 | $p < 0.01$** |
| direct environmental behaviors | 5.3 / 1.2 | 4.7 /1.3 | $p < 0.001$*** |
| indirect environmental behaviors | 3.6 / 1.8 | 2.7 /1.5 | $p < 0.001$*** |
| competence | 5.5 / 1.4 | 4.3 / 1.7 | $p < 0.001$*** |
| family behavior | 4.8 / 1.6 | 4.5 / 1.5 | $p < 0.05$* |
| self-image | 4.1 / 1.6 | 3.7 / 1.3 | $p < 0.01$** |

**Table 1. Mean differences of demographic data and different variables ([1]Chi-Square-Test).**

Caretaking reasons of Expressive Caregivers are significantly stronger than those of Reserved Caresavers (Table 2). In contrast, Reserved Caresavers lead the ratings of non-caretaking reasons on a significant ($p < 0.05$*) or a highly significant ($p < 0.001$***) level.

| | Expressive Caregivers μ/σ | Reserved Caresavers μ/σ | Mean Difference (t-test) |
|---|---|---|---|
| *n* | 224 | 253 | |
| **Caretaking reasons** | | | |
| fun | 4.3 / 1.6 | 3.9 / 1.4 | $p < 0.01$** |
| extending life | 4.7 / 2.0 | 4.2 / 1.8 | $p < 0.01$** |
| saving money | 4.6 / 1.9 | 4.3 / 1.7 | n.s. |
| environment | 4.4 / 1.8 | 4.0 / 1.5 | $p < 0.01$** |
| education | 4.3 / 1.8 | 4.0 / 1.4 | n.s. |
| **Non-Caretaking reasons** | | | |
| costs | 3.1 / 1.6 | 3.4 / 1.4 | $p < 0.05$* |
| no time | 3.2 / 1.6 | 3.6 / 1.4 | $p < 0.01$** |
| no motivation | 3.2 / 1.6 | 4.1 / 1.4 | $p < 0.001$*** |
| I don't care | 2.4 / 1.5 | 2.8 / 1.3 | $p < 0.01$** |
| missing trust | 2.8 / 1.5 | 3.2 / 1.4 | $p < 0.05$* |
| no equipment | 3.1 / 1.4 | 3.5 / 1.6 | $p < 0.01$** |

**Table 2. Mean differences of reasons to (not) take care of products.**

An ordinary least square regression with a stepwise procedure was conducted to identify drivers of product care. *Product care* served as the dependent variable. As independent variables, green consumption values, perceived environmental knowledge, environmental concern, direct environmental behaviors and indirect environmental behaviors, as well as the three single-items perceived own competence, family behavior and self-image were used, complemented by the five caretaking reasons (+) fun, extending lifetime, saving money, environment and education as well as the six non-caretaking reasons (-) costs, no time, no motivation, no relevance, missing trust in myself and no equipment – altogether 19 independent variables.

The final model contains eight calculation steps, whereby the corrected explained variance (corr. $R^2$) continuously improved from 0.165 to 0.381 (Durbin Watson = 1.4; $F(476) = 37.7$; $p < 0.001$***). Ten variables were excluded, resulting in the identification of eight relevant drivers of product care behavior (Table 3).

| Independent variables | Stand. B | Significance |
|---|---|---|
| perceived own competence | 0.306 | 0.000 |
| indirect environmental behaviors | 0.250 | 0.000 |
| no motivation (-) | -0.209 | 0.000 |
| no relevance (-) | -0.183 | 0.000 |
| extending lifetime (+) | 0.106 | 0.005 |
| fun (+) | 0.100 | 0,008 |
| green consumption values | 0.088 | 0.025 |
| education (+) | 0.079 | 0.033 |

**Table 3. Relevant drivers of product care behavior.**

In summary, we identified two clusters of young consumers who differ not only on product care but on all determinants such as green consumption values, environmental concern and family behavior (see Table 1). In addition, most reasons for (not) taking care of products also differed between these two groups (see Table 2). We found eight drivers of product care across both groups (see Table 3). These findings allow us to suggest implications for policymakers.

## Implications

We used the Behaviour Change Wheel by Michie et al. (2011) to derive reasonable policy interventions from our findings. Its underlying COM-B model defines capability, motivation, and opportunity as relevant determinants of behavior. These factors have been shown to be crucial for product care in previous research (e.g., Ackermann et al., 2018). Also, in this study, we identified low capability and lack of motivation as barriers to product care. Consequently, we suggest the following interventions and policies:

Providing **information** about product care should not only be done by manufacturers but also via mass media campaigns to increase knowledge and understanding. Although Expressive Caregivers already feel more competent than Reserved Caresavers, **education** can increase capability and motivation for both groups and should ideally be part of curricula at schools. As fun has already been shown to be a relevant driver of product care, stimulating positive feelings through communication or marketing might be a valid approach related to **persuasion**. **Incentivization**, for example, by organizing prize draws or other challenges for good product care behavior, can also be used. This approach might be especially relevant for Expressive Caregivers who already enjoy telling others about taking care, but also for Reserved Caresavers who are given an easy way to demonstrate their care activities. **Coercion** and **restrictions** through legislation could be a too harsh approach for consumers and should better be applied for manufacturers, as it is done by the Right to Repair (European Parliament, 2022). More relevant interventions addressing consumers include **enablement**, which could be realized by organizing and supporting local repair communities and repair cafés, thereby enhancing consumers' product care skills. Further support could be given through **training** at these local initiatives or on a website provided by policymakers. **Modelling** seems to be one of the most relevant possible interventions: As our data shows that product care behavior of family members plays an important role, we encourage policymakers to proactively widen this factor: Role models cannot only be found within the family, but could also be other opinion leaders such as public figures.

Communication campaigns that promote product care as an activity that saves money and protects the environment – some of the primary reasons for taking care – as well as a behavior that corresponds with social norms might be the most promising approach to foster product care among young consumers.

## Conclusions

This study aimed to explore factors influencing product care among young consumers to get a deeper insight into their current care behavior and to propose consumer-oriented interventions for policymakers based on these insights. We identified two distinct clusters of young consumers, and we developed interventions for policymakers that consider these clusters as well as further insights into the determinants of product care. While our suggestions are based on empirical data, we highly encourage the practical implementation of such interventions and a scientific evaluation to ensure their efficiency.

# Sustainable Business Models for the Second Use of Electric Vehicles Lithium ion Batteries in an Ecosystem Context: A Review

**Saad Ahmed [(a)], Elli Verhulst[(a)], Casper Boks[(a)]**
a) Norwegian University of Science and Technology, Trondheim, Norway

**Keywords**: Sustainable business models; Ecosystems; Electric vehicles; Battery second use; Circular economy.

**Abstract**: Repurposing electric vehicle lithium-ion batteries (EV LiBs) for second use can potentially prolong the life of the batteries, partially close the value chain loop and contribute towards circularity. Rapid adoption of EVs has paved way for new business models incorporating sustainability for the EV LiB second use industry. This study is conducted through a literature review to provide a better understanding of current sustainable business models (SBMs) for second use EV LiBs and their position in the related ecosystem. The initial insights suggest that SBMs can play an important role in adaption for the EV LiB second use. However, the EV LiB ecosystem is complex consisting of multiple stakeholders and interconnected activities. These stakeholders include but are not limited to automotive original manufacturers, batteries collectors, system integrators, users, and repurposers etc. Their BMs can be interdependent, affecting one another positively, negatively, or symbiotically and influencing the overall value of LiB second use. This paper synthesizes three research fields: SBM, Ecosystems, and Second use EV LiBs and provides insights that support the need for considering SBMs in an ecosystem context for second use. It also presents SBM types for various stakeholders in existing second use ecosystems. Furthermore, it provides the basis for further research into SBM interactions and SBM innovations in the EV LiB ecosystem.

## Introduction

The continuous increase in the sale of electric vehicles (EV) has increased the number of lithium ion batteries( LiBs) being produced (IEA, 2022; Winslow et al., 2018; Wrålsen et al., 2021). It is not ideal to use these batteries in the EVs once their capacity drops below 80% and hence should be either recycled or repurposed for second use. The materials present in LiBs are hazardous and if treated irresponsibly, can result in adverse environmental impacts at their end of life (EOL) ((Jiao & Evans, 2018a; Kim et al., 2021). According to estimates, by 2030 more than 200,000 metric tons of LiBs will have to be recycled in EU alone, which is expected to double by 2035 (*Building a Circular Battery Economy in Norway*, 2021). Moreover, the recycling processes are not yet efficient enough (Heelan et al., 2016) and it is therefore pertinent to prolong the use phase of these batteries.

Repurposing EV LiBs in less demanding energy storage systems (ESS) can potentially prolong the use phase and partially close the value chain loop while reducing the environmental impacts and increasing the economic benefits (Chen et al., 2019; Montes et al., 2022). However, there are numerous barriers that need to be addressed to make repurposing economically, environmentally, and socially viable. A potential way to achieve this is by innovating business models and integrating sustainability initiatives into the core business activities of the stakeholders. This can be a challenge as the EV LiB value chain is complex and consists of multiple stakeholders across different industries. Understanding the value chain in a circular context and mapping the ecosystem can contribute to understanding how these stakeholders and their business models interact and innovate (N. Bocken et al., 2016; Cheng et al., 2022; Wrålsen et al., 2021; Zulkarnain et al., 2014).

The business models having sustainability at their core, considering economic, environmental, and social aspects, are known as sustainable business models (SBM) while circular business models (CBM) are a type of SBMs that can close, slow, narrow, intensify, and dematerialize loops to promote sustainability (Geissdoerfer et al., 2018). Although CBMs do not address the social dimension (Murray et al., 2017) the literature of SBMs and CBMs is partially overlapping, and hence both are considered in this paper.

Initial investigation reveals an emerging field in the literature on SBM perspectives (Evans et al., 2017; Geissdoerfer et al., 2017; Lüdeke-Freund, 2020; Wrålsen et al., 2021). However, to date there is scarcity in the literature about the interrelation between SBM perspectives in an ecosystem context for the EV LiB second use market. Addressing this gap, this paper investigates the state of the art on SBMs for the second use of LiBs focusing on repurposing in an ecosystem context.

## Methodology

The study applied a literature review covering three main themes: Sustainable business models, ecosystems, and second use EV lithium-ion batteries. The literature search consisted of journal articles, conference papers, research reports and to some extent grey literature like news, press releases and company websites. A database search through Scopus and Google Scholar was conducted followed by snowballing, while Google search was used to search for grey literature. A combination of keywords such as *sustainable business models, circular business models, EV lithium-ion batteries, second life or second use of EV lithium ion batteries, Value chain EV lithium-ion batteries, EV Lithium ion batteries ecosystems, circular ecosystems, reusing and repurposing* was used for the search. Purely techno-economic studies analyzing the technical efficiency of recycling or the life cycle cost effectiveness of the batteries while neglecting the value proposition, stakeholder perspectives, and environmental and social aspects of the business models were not considered. After screening, a total of 28 core articles were selected for review while additional articles were selected through snowballing.

## Results

A funnel approach is used to present the interrelationship between the three selected research themes. At first, general concepts related to SBMs and second use EV LiBs are presented, and then these concepts are analyzed in the context of ecosystems.

### *Sustainable Business Models (SBMs)*

The main purpose of a business model is to identify how value is created, delivered, and captured by a business (Johnson et al., 2008; Osterwalder et al., 2010). Until recent times, businesses mostly focused on the economic value, but now sustainability has become an important factor on how they deliver their services (Miller, 2020; Osterwalder & Pigneur, 2010). A BM where sustainability is integrated in the core business activities, and includes pro-active stakeholder engagement is called a sustainable business model (SBM) (Geissdoerfer et al., 2018). SBMs can be viewed from both systems and firm-level perspective while also considering environment and society as stakeholders (N. Bocken, 2021; Boons & Lüdeke-Freund, 2013; Stubbs & Cocklin, 2008). They offer tools that can deliver social and environmental sustainability (Lüdeke-Freund, 2010), and provide sustainable value to stakeholders that are affected by the business (Nosratabadi et al., 2019).

Some of the emerging topics within this field are related to tools and methods such as BM experimentation and SBM archetype strategies that businesses can use to transform their BMs. Other fields include assessment of the impacts of such BMs on the firms, their rebound effects, and extending product lives through BM innovations (N. Bocken et al., 2013; N. Bocken, 2023). For businesses, it is considered essential that new sources of sustainable value are created to attain competitive advantage (Jiao & Evans, 2016a).

### *Second use of the EV LiBs*

An EV LiB consists of multiple modules comprising of battery cells. These modules consist of a specific chemistry, battery management system (BMS), and thermal management system catered to the kind of application they are used for (Saw et al., 2016). When the LiBs reach 70%-80% of their capacity, they are no longer used in EVs. However, multiple studies suggest that these batteries can still be repurposed in less demanding applications for second use (Reinhardt et al., 2019). Ideally, repurposing the batteries to be used in energy storage systems (ESS) is the most sustainable way to prolong the battery life and mitigate environmental negative effects (Bobba et al., 2018; Chirumalla et al., 2022; Islam & Iyer-Raniga, 2022; Jiao & Evans, 2016b; Schulz-Mönninghoff & Evans, 2023). This also delays the recycling phase which is considered inefficient and unsustainable (Golmohammadzadeh et al., 2022). These batteries are mostly used in grid stabilization, residential backup power, load levelling and backup storage systems for the electricity generation grids (Wrålsen & Faessler, 2022).

The spent EV LiBs have to go through disassembly, testing, necessary reparations, battery management system adjustments, reassembly of module and pack, and repackaging for second use application (Reinhardt et al., 2019). The kind of second use application they are used for depends on factors such as state of health (SOH), market conditions, chemistry etc, which are assessed by the battery handler (Ahmadi et al., 2017; Shahjalal et al., 2022; Wrålsen et al., 2021). Monitoring the battery condition and effective data traceability can potentially help in better control of the second use market (Antônio Rufino Júnior et al., 2022).

### *SBMs in the second use of EV LiBs*

Extending product life can contribute towards circularity, and SBMs can play a fundamental role as an enabler (Boons & Lüdeke-Freund, 2013). With an ever increasing market for EVs, the second use LiB market is naturally growing and new business models are emerging (Jiao & Evans, 2016b). Several SBM archetypes have been proposed in the literature based on the environmental, social, and economic aspects (N. Bocken et al., 2014). These archetypes are further used in the context of second use of LiBs that provides an overview of how SBMs are developed in the second use industry (Reinhardt et al., 2020). Three fundamental actors for the EV LiB second use market are proposed in the literature: Automotive original equipment manufacturers (OEMS), intermediaries, and customers, where an intermediary collects, repurposes and sells the second use batteries (Klör et al., 2015), while Bräuer et al (2020) have explored how transactions take place in a second use complex system, as an EV LiB can be traded as it is, or disassembled into components, repurposed and integrated into another system, or its BMS can be reconfigured to be used in another application.

Relatedly, Jiao and Evans (2018b) and Rufino Júnior et al (2023) have proposed three types of SBMs related to EV LiBs: standard, collaborative, and integrated business models. The business model of selling used batteries by the OEMs directly to the battery repurposers is considered as a standard business model, while in a collaborative business model, the OEMs and the battery repurposers collaborate to reach a final solution. This collaboration could be 1) assistive collaboration where OEMs assist battery repurposers, 2) OEMs codevelop the final solution with repurposers, and 3) Repurposers provide solution to the OEMs. While in an integrated business model the ownership is retained by the OEM. Other studies have proposed two types of second use BMs: refurbishing, where the second use batteries are again used in an EV but in another market where short range and low capacity are not a concern and repackaging, where the spent batteries are used in another application (Albertsen et al., 2021; Wrålsen et al., 2021)

The current research points out to several barriers that exist for the EV LiB SBMs. These include but are not limited to financial, technological, market, social, and legislative barriers (Wrålsen et al., 2021). These barriers are further categorized in the table 1:

| Category | Barriers | Source |
|---|---|---|
| Technological | 1. Variable battery design, chemistry, and management system<br>2. High optimization for first life leads to mismatch for second life.<br>3. Limited data sharing between OEMs and Repurposers<br>4. Unclear state of health | (Balasingam et al., 2020; Börner et al., 2022; Montes et al., 2022; Reinhardt et al., 2019) |
| Market | 1. Raw materials supply considerations<br>2. Price reduction of the new batteries<br>3. Battery availability (economies of scale)<br>4. Disassembly and repackaging costs.<br>5. Unclear value proposition<br>6. Transportation costs | (Albertsen et al., 2021; Hu et al., 2021; Kumar et al., 2021; Malinauskaite et al., 2021; Rajaeifar et al., 2022) |
| Social | 1. Safety and reliability uncertainty<br>2. Lack of awareness and information<br>3. Unclear user incentives | (Börner et al., 2022; Sopha et al., 2022; Wrålsen et al., 2021) |
| Legislative | 1. Policy incentives unclear<br>2. Lack of legislation | (Lee et al., 2021; Wrålsen et al., 2021; Yang et al., 2021) |

**Table 1. SBM barriers for second use EV Libs.**

### *EV LiB SBMs in the context of eco-systems*

Most of the BM literature is focused on a single firm view around the notion of value generation from a value chain perspective (Kanda et al., 2021). However, this perspective can be limiting as it only considers stakeholders that directly contribute to the production, use, reuse and recycling of the EV LiBs without necessarily taking into account other stakeholders that can directly or indirectly affect this value chain. An ecosystem perspective, on the other hand, provides a much broader systemic perspective considering actors beyond the value chain (Barquete et al., 2022; N. Bocken et al., 2013; Hellström & Wrålsen, 2020; Kapoor, 2018). It is defined as a diverse set of stakeholders interconnected in a complex structure in which both competition and cooperation may exist (Peltoniemi & Vuori, 2008), collectively generating a common output or value proposition (Adner, 2017).

An ecosystem can provide a systemic view of different stakeholders and their interlinked business models interacting with each other to create common value (Fobbe & Hilletofth, 2021; Schiavone et al., 2021; Tsujimoto et al., 2018; Zulkarnain et al., 2014). Mapping the ecosystem can illustrate these interactions and dependencies between the existing stakeholders and their BMs leading to development of new BM designs (N. Bocken et al., 2018; Weiller & Neely, 2013).

Similarly, in the EV LiB ecosystem, several other stakeholders are also considered which are otherwise neglected in a value chain perspective. Hellström and Wrålsen (2020) provide a list of actors in a typical EV LiB repurposing ecosystem. These are shown in the figure 1:

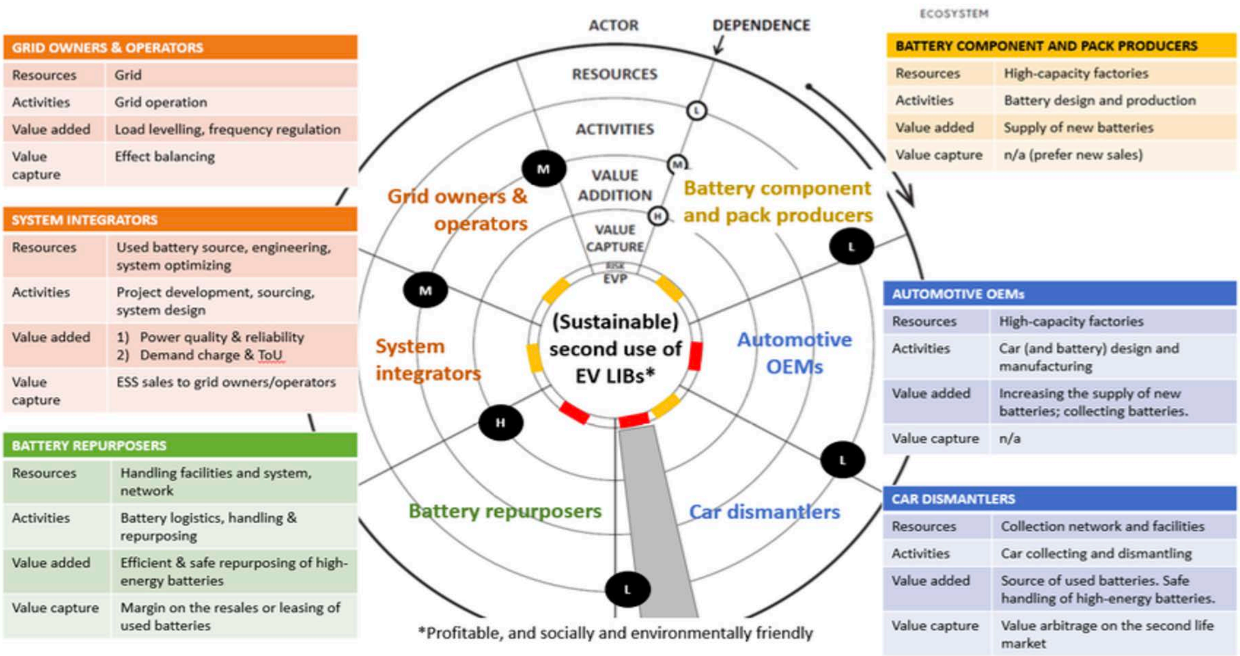

**Figure 1. BATMAN IFE Report 2020 Hellström and Wrålsen (2020).**

## *Examples of SBMs in the second use EV LiB ecosystem*

A review of grey literature provides an overview of actors and their SBMs currently organized in existing ecosystems, with an emphasis on the European context. This is shown in table 2, and by no means represents all the actors within an ecosystem but only provides examples. These SBM types have been categorized based on the business activities, partnerships, and value being delivered by the actors and are based on the study conducted by Jiao and Evans (2018b). These types can be further categorized into different sub-types of SBMs but it is beyond the scope of this study. Furthermore, in an ecosystem, these SBMs can be interdependent on each other.

| Name | Actor | Collaboration Examples | SBM Type | Region | Second Use | Source |
|---|---|---|---|---|---|---|
| Nissan | Automotive OEM | Ecostor + Agder energi + Morrow Batteries + NorskGjenvenning | Collaborative Business Model | Norway | Energy storage system | (*Ecostor*, 2021) |
| BMW | Automotive OEM | Offgrid Energy | Collaborative Business Model | UK | Mobile Power units / Fast charging | (*BMW Group UK Second-Life Battery Solution in Partnership with Off Grid Energy.*, 2020) |
| Volkswagen | Automotive OEM | Mostly internal but also some cooperative projects | Integrated Business Model | Germany /Global | Energy Storage System | (*Second life for used batteries*, 2019) |
| Renault | Automotive OEM | Connected Energy | Collaborative Business Model | UK | Energy Storage system | (*A Second Life for Batteries*, 2020) |
| Mercedes | Automotive OEM | Batteryloop | Collaborative Business Model | Sweden | Energy Storage System | (Randall, 2022) |
| 4R Energy Corp | Automotive OEM | Joint venture by Nissan and Sumitomo corp | Integrated Business Model | Japan | Energy Storage / Fast Charging | (*Nissan Gives EV Batteries a Second Life*, 2021) |
| Grønvold's Bil Demontering AS | Car Dismantler | Partnership with insurance companies | Standard Business Model | Norway | Sell to Repurposers | ("Gbd.No," n.d.) |
| Betteries | Repurposer | Example: Partnership with Mobilize | Collaborative /standard Business Model | Germany | Modular solutions for energy storage | (Hoenig, 2021) |
| Statnett | Grid Owner/ Operator | Norwegian State owned | Standard Business Model | Norway | - | (*statnett*, 2023) |

**Table 2. SBM types in 2nd use EV LiB ecosystem.**

## Discussion and Conclusions

Extending the lifetime of products is one of the fundamental requirements to build circularity (N. M. P. Bocken et al., 2016; *The Circularity Gap Report*, 2022). This is also considered an important step towards a more sustainable electrification of the transport sector. Extending life span of the LiBs after their life in the EVs has thus become an emerging research topic. Several studies suggest that repurposing EV LiBs into second use in less demanding energy storage applications can extract the residual value of the spent batteries and provide economic, environmental, and social benefits (Reinhardt et al., 2019; Wrålsen et al., 2021). SBMs and business model innovations are considered to play a pivotal role in making repurposing of EV LiBs viable. However, until now, the prospects of adaption of second use batteries have not been optimistic because of the various SBM barriers mentioned in the literature including technical, market, legislative, and social barriers.

SBM perspective in the second use of EV LiBs has only recently started to gain attention from the researchers and industry (Jiao & Evans, 2018b). Several authors have proposed different business model typologies and archetypes which can be used in the second use of EV LiBs (Jiao & Evans, 2016a) but the experimentation of these BMs in real life has been limited. An interesting point for discussion is whether the existing knowledge of SBMs and the associated use cases in the research can be applied to the second use EV LiB industry or if the second use EV LiB is fundamentally different from other cases.

Several circular economy studies indicate that companies cannot be seen as isolated entities, and there is a need to understand the value networks which they are a part of in larger ecosystems (Barquete et al., 2022). There has also been a growing interest in the BM literature to have a more systemic view (N. Bocken et al., 2013). However, the research so far has mostly focused on the value chain perspectives of the LiB second use, neglecting the broader ecosystem of which the EV LiB value chain is a part of. Mainly, the discussion about policy makers, competitors, users and indirect stakeholders (non-governmental organizations etc), and their influence on the stakeholders' BMs in an ecosystem context has been missing. These stakeholders can positively, negatively, or symbiotically affect business models in the value chain of the EV LiB. For example, the business model of a second-life batteries storage facility can be affected if the business model of an OEM changes. Moreover, both businesses may have to innovate their business models if there is a shift in the policy of the local government where they operate.

However, how can multiple stakeholders within this ecosystem innovate their BMs to become more sustainable is yet to be explored. Therefore, this study aims to contribute to an established field of circular economy research by synergizing SBM, Ecosystems, and Second use EV LiB literature. Further research in this area and a comprehensive analysis of the second use EV LiB ecosystem can contribute to understanding the BM innovations taking place because of the BM interactions between the stakeholders and pave way for adaption of second use EV LiBs.

**Keywords**: Sustainable fashion; Consumer behavior experiment; Subscription service; Access-based economy; Consumer perception.

**Abstract**: Fashion rentals of casual to office wears present a particularly interesting business model for sustainability through mitigating personal clothing consumption. While environmental impact mitigation is theoretically possible, past studies have shown that several consumer behavior conditions exist to capture the environmental benefit. Among the conditions, changes in consumer behavior and perception using fashion rental services are found to be the critical factors. To examine the changes in consumer behavior brought by the fashion rental services and deduce their environmental implication, we performed a consumer behavior experiment where 22 participants used a fashion rental subscription service for three months in Japan. The experiment data were analyzed qualitatively and quantitatively for the changes in absolute volume of consumptions (i.e., clothing purchases) and garment wear intensity (i.e., weartime per garment). The results suggested that absolute reduction of garment consumption was limited quantitatively, but we found garments may be purchased more selectively through interviews. The intensifying use was observed for skirts and dresses, implying rentals may be effective for a specific category of garments.

## Introduction

Today, fashion has become an infamous example of a global environmental problem, where mass production, mass consumption, and mass disposal continue to persist. One estimates that clothing production volume has doubled in the past twenty years while the lifetime wears have halved (Ellen MacArthur Foundation, 2017).

To reduce the environmental impact led by the current consumption patterns of garments, fashion rental services have been attracting attention. Rental services offer a consumption pattern alternative to purchasing of goods, which could reduce the material demand in the society while meeting consumer needs. Among them, fashion rentals of casual to office wears present a particularly interesting business model for sustainability (Amasawa et al., 2023; Piontek et al., 2020; Zamani et al., 2017). Unlike occasion wear rentals that are rented for a short-term, most casual wear fashion rentals adopt a subscription model, where customers access a specific number of garments in a month. Additionally, while the garment rented in occasion wear rentals are generally worn only once during its rental period, the nature of casual wears provides an extended opportunity to wear the rented clothing, which could increase the lifetime wear and reduce clothing purchases. As a result, fashion rental services of casual wears could reduce the environmental impact through mitigating personal clothing consumptions.

While the environmental impact mitigation is theoretically possible, past studies have shown that several consumer behavior conditions exist to capture the environmental benefit. For example, Piontek et al. (2020) stated that clothing rentals need to avoid consumption of new infrequently worn garments through their life cycle assessment study on fashion rental services in Germany and Japan. Johnson and Plepys (2021) also showed a resembling conclusion that rentals need to increase the wear time and consumers need to use rentals to substitute their purchasing. In other words, the environmental implication of fashion rental services is decisively influenced by the consumer behavior in fashion rentals. Consumers of fashion rental services have been investigated for their motivations for the service use (Camacho-Otero et al., 2019) but the changes in consumer behavior and perception using fashion rental services are yet to be understood.

To examine the changes in consumer behavior brought by the fashion rental services and deduce their environmental implication, we conducted a consumer behavior experiment. The experiment asked participants to use a fashion rental subscription service for three months in Japan. This paper presents the overview of the experiment and the results obtained up to today.

## Method

This research collected qualitative and quantitative data on clothing consumptions through an experimental use of clothing rentals. The collected data were analyzed for consumer behavior conditions that directly relate to the environmental impact.

### *Social experiment overview*

The consumer behavior experiment recruited 22 female participants in Japan by word-of-mouth method. The participants were asked to use a fashion rental subscription service that rents casual to office attires for three months. The fashion rental service allows subscribers to borrow three garment pieces selected by stylists each month. The garments were always rented out as a set of three types: tops, bottoms (skirts or pants), and dresses. The subscribers must return the set of three pieces to exchange for the new garments. We used a subscription membership with unlimited exchanges, which allows participants to freely exchange garments. The experiment took place in October 2022 to mid-January 2023.

The experimental design applied One Group Pre-Test-Post-Test from Pre-Experimental method (Malhotra, 2007). The data collection process contains in-depth interviews performed before and after the experiment, and a monthly survey. The in-depth interviews aimed to understand the consumer attitudes and perceptions on their clothing consumption. The monthly survey asks for the number of garments they rented, the number of wears for each garment, the level of satisfaction on the rented garment, and garment purchases during the experiment period.

### *Analysis method*

The environmental impact from clothing consumptions were implicitly analyzed by examining the following two aspects:

a) *Absolute reduction of consumption*: whether the clothing rental replaced purchasing to reduce the overall clothing purchases.
b) *Intensifying use*: whether the clothing rental increased the lifetime wear of the garment relative to when owning the garment

The survey data was first analyzed quantitatively for the two aspects. The qualitative data was then used to understand the consumer motivations and factors influencing the quantitative results.

## Results and Discussions

### *Participants' basic information*

The participants' age ranged between 20s to 50s, where 60% of them were 20s and 30s. All participants except one were all employed. Among them, 30% have considered using a fashion rental service, and half of them were unaware of their existence. Table 1 shows the consumer characteristics of the participants based on a categorization from a literature (Johnson & Plepys, 2021). From the study by Johnson and Plepys (2021), consumers categorized in *Stand-out* and *Eco-friendly* were likely to replace dress rentals with a purchase, which would satisfy the aspect a) absolute reduction. Our participants largely fell into *Influencer* or *Avoid* category, which suggested that environmental benefit from using clothing rentals may be limited.

| **Consumer type** (Johnson & Plepys, 2021) | **Characteristics** | **Number of participants** |
|---|---|---|
| Stand-out | Buys unique clothing | 2 |
| Bargain | Buys cheaper alternatives | 4 |
| Influencer | Buys latest styles | 7 |
| Avoid | Buys only when needed | 9 |
| Eco-friendly | Buys sustainable alternatives | 0 |
| Fitting-in | Buys similar styles to friends | 0 |

**Table 1 Consumer type of the participants.**

*Clothing consumption trends*

We found that 80% of the rentals were returned within 14 days, and 25% of the rentals were returned within less than 4 days, which indicates that some rentals had a short rental cycle with a limited opportunity to be worn. When we analyzed the number of garment pieces rented by each participant, the average was 6 pieces per month, which equates to 2 rentals. We also found that only 60% of the rented garments were actually worn; thus, whether the rented garments match the user's style preference decisively influence the environmental impact on personal clothing consumption.

When the garment purchase behavior was analyzed, participating in the rental service appeared to have limited influence. The total number of garment purchases by the participants ranged between 20 to 33 pieces whereas the monthly average prior to the experiment was around 37 pieces. One reason for the consistent garment purchasing behavior is the seasonality. January has new year sales, which stimulates purchase motivation. Another interesting find was some participants purchased the rented garments. Several participants also noted that they wanted to buy the rented garment, but the price was considered expensive, so they purchased an alternative with a similar style. Thus, clothing rentals have encouraged users to purchase garments to certain extent.

Additionally, when the weartime of the rented garments was analyzed and compared against the average weartime for purchased garments from our past study (Amasawa et al., 2022), the weartime increase from purchased to rentals was only observed with skirts and dresses. In other words, skirts and dresses were able to intensify its use through rentals, but pants and tops were not. Because skirts and dresses are garment category which of its design is likely to be more influenced by trends, which may have led to increase in weartime when rented.

*Consumer voices*

Table 2 shows excerpts of the Post-experiment interview results categorized by the factors influencing the two aspects for environmental impact reduction. Based on the results, clothing rentals may be effective in reducing clothing purchases through satisfying the consumer wants for "a new piece." Another interesting consequence of clothing rentals was gaining a deeper understanding in the personal styles. Through the opportunity to try out diverse garment styles, many participants noted that they were able to define their personal styles better than before. As a result, the participants became more selective when purchasing garments, which consequentially would help to prolong the garment lifetime and increase weartime of the garments.

| | Positive influence | Negative influence |
|---|---|---|
| a) Absolute reduction | - Less impulsive shopping<br>- Better understanding in my personal style | - Encouraged shopping because rented garments were unsatisfactory |
| b) Intensi-fying use | - Learned the importance of trying out before the purchase<br>- Began wearing clothes that were not worn frequently | - Short rental periods to try out many styles<br>- Returned the rentals quickly because the rental garments were unsatisfactory |

**Table 2 Consumer voices related to clothing consumption.**

## Conclusions

Our social experiment on clothing rentals suggested that absolute reduction of garment consumption was limited quantitatively, but we found that participants may have become a more selective shopper through interviews. The intensifying use was observed for skirts and dresses, implying rentals may be effective for a specific category of garments. Further analysis, especially on qualitative data, is needed to understand the motivation of consumer behavior.

# Secondhand shell jackets are better than users think: A comparison of perceived, assessed and measured functionality throughout lifespans

**Hampus André*[(a)], Louisa Swenne*[(b)]**
a) KTH Royal Institute of Technology, Stockholm, Sweden
b) Mid Sweden University, Östersund, Sweden

*Both authors contributed equally to this work

**Keywords**: Circular economy; Obsolescence; Functionality; Performance; User perception.

**Abstract**: Knowledge about obsolescence and its possible causes is instrumental to extend product lifespans. Product obsolescence may be caused by both subjective perceptions as well as objective and measurable deterioration of functionality. In order to extend lifetimes by avoiding and reversing obsolescence, this study addresses the current knowledge gap on how functionality of products develops over time, using a case study on shell jackets for outdoor recreational activities. Functionality over time is compared in terms of user perceptions, ocular assessments, laboratory measurements and, in addition, price. Data were collected at beginning of use, secondhand resale and end-of-life. In addition to ocular assessments and laboratory measurements, a survey was used to collect data from users on e.g. perceived functionality, price and duration of use span. Linear representations of perceived functionality and price decline more rapidly (5-6% per year) than assessed and measured functionality (both around 3% per year). This could be explained by properties such as appearance, which are included and seemingly important to user perceptions and price, but which are not assessed nor measured. The perception of such properties as low seems to be a more relevant cause of obsolescence than inadequate performance. This points to, for instance, timeless design to avoid obsolescence. The finding that measured functionality remains relatively high over time is important since concern about performance is a key barrier to secondhand sales. Information policy, such as performance-labelling, could thus contribute to reversing obsolescence. Future research could test the robustness of these findings as well as their generalizability to other products.

## Introduction and aim

The circular economy is largely a vision of how environmental impacts of consumption can be reduced by avoiding or reversing obsolescence to extend product lifespans. The term obsolescence is used here to describe a state at which one use span of a product ends (Proske & Finkbeiner, 2019), after which it either:

- gets discarded (reaching its end-of-life)
- has its obsolescence reversed through circular economy measures such as reuse or repair to be used for an additional use span.

There are a variety of reasons why products become obsolete to a user: e.g. emotional, psychological, functional and economic (Cooper, 2004). These reasons can be understood as a mismatch between user requirements and states of product properties (André and Björklund, forthcoming; Van Nes, 2016). For instance, functional obsolescence arises when the state of the performance of a product does not fulfil the user's performance requirements. This can happen either because the user's requirements have increased or because the state of the product's performance has declined since the user obtained the product. In the literature, this is often described as a distinction between objective and subjective obsolescence (Cooper 2004; Proske and Finkbeiner, 2019).

In addition to subjective and objective reasons, obsolescence can occur because of mismatches with respect to any given product property. As a result, for any given product there are numerous reasons for obsolescence.

Knowledge about the reasons for obsolescence, both with respect to product states and user requirements in terms of the relevant product properties, is instrumental to reversing obsolescence through circular economy measures (Van Nes, 2016). Such knowledge can be used, on one hand, to inform design in order to avoid obsolescence in the first place (Van Nes, 2016) and, on the other, to match-make between states of obsolete products and requirements of potential secondhand users. As yet, such knowledge is very limited (Cooper and Claxton, 2022).

In the EU Circular Economy Action Plan, textile is identified as one of the prioritized sectors due to its high environmental impact and potential for increased circularity (European Commission, 2020). Shell jackets for outdoor recreation are interesting textile products in the context of obsolescence and circularity since both subjective and objective reasons for obsolescence are highly relevant. They are technical garments on which users typically have high requirements on measurable performance-related product properties such as water penetration resistance and repellency, breathability and air permeability. At the same time, many users have high requirements on less objectively measurable properties such as appearance (André and Björklund, 2022).

In previous research, it has been found that reluctance to buying shell jackets secondhand is often rooted in lack of knowledge about the states of performance and quality since these properties may have declined during the first use span (André and Björklund, forthcoming). The same concerns are relevant for other, non-technical, clothing (Laitala and Klepp, 2018; Gullstrand Edbring et al, 2016). For such reasons, it has been discussed that increasing circularity of clothing could benefit from making information about functionality and expected longevity available to potential users (Cooper and Claxton, 2022) through e.g. digital product passports. Users typically expect price to be indicative of such properties but the strength of this relationship has been questioned (Rao, 2005; Cooper and Claxton, 2022) and, to our knowledge, not been investigated in the context of secondhand products.

Motivated by the interest in extending lifespans of textile products, this research aims to provide knowledge that can help inform strategy and policy to avoid and reverse obsolescence. To do so, the study investigates and compares the functionality of shell jackets over time in terms of user perceptions, ocular assessments performed by researchers, laboratory measurements and, in addition, price.

## Material, methods and assumptions

In this section the material, methods and assumptions for perceived, assessed and measured functionality are described.

### *Perceived functionality and price*

The data for perceived functionality were obtained through surveys targeting users from three secondhand and five conventional outdoor stores for clothing and equipment. The users who either sold or bought jackets at the secondhand stores rated the condition of the jackets according to the scale “New-Excellent-Good-Decent-Poor" at the time of secondhand resale. They also reported on original and secondhand sales price. Buyers reported on expected use span and expected condition at end-of-life. In the conventional stores, users reported on price, expected lifespan and expected condition at end-of-life. (André and Björklund, forthcoming)

The surveys were distributed both in the physical secondhand and conventional stores via QR-codes and through the communication channels of the secondhand stores. In total, the surveys had 71 respondents, 51 from the secondhand stores and 20 from the conventional stores. (André and Björklund, forthcoming)

### *Assessed and measured functionality*

To gather data for assessed and measured functionality, 16 secondhand shell jackets and 10 end-of-life shell jackets were bought from the same three outdoor secondhand stores as the surveys were distributed in. The end-of-life jackets were received from friends and colleagues who no longer used them due to their poor condition. The end-of-life jackets were perceived to have no monetary value.

An ocular inspection protocol was established to enable a structured assessment of the secondhand and end-of-life jackets. The protocol focussed on 14 main shell jacket components: zippers (front, ventilation, outer and inner pockets), arm end hook and loop tapes, bottom and hood cords, hood cap, hanger loop, fabrics (outside, inside, arm end, bottom), and sealed seams. By using the inspection protocol, a researcher rated all components according to the same scale that was used in the user survey: “New-Excellent-Good-Decent-Poor".

Measured functionality comprises four performance-related properties related to the fabric: water penetration resistance and repellency, breathability and air permeability. To evaluate the measured functionality of the secondhand and end-of-life shell jackets, six samples in total were cut from each jacket: from the hood, shoulders and back. Water repellency and air permeability were tested on all six samples while water penetration resistance and breathability were tested on two samples each.

All test methods used were based on ISO (International Organization for Standardization) standards, except for air permeability which was tested with an Akustron air permeability tester (Rycobel, 2023). The water repellency and breathability test methods were based on ISO 4920:2012 (ISO, 2012) and ISO 15496:2018 (ISO, 2018). The test methods were not fully compliant with the ISO standards since the temperature (20.0±2.0°C) and relative humidity (65.0±4.0%) requirements of ISO 139 (ISO, 2005) were not met. Nevertheless, during the tests the used lab had a constant temperature of 23°C and relative humidity of 28%. The water penetration test method based on ISO 811:2018 (ISO, 2018) was performed in a conditioned textile lab. However, the test method was not fully compliant since the test endpoint of the method included not only three drops but also full surface perspiration and leakage due to broken fabric. (Swenne, forthcoming)

### *Assumptions and calculations*

To plot functionality over time, data on perceived, assessed and measured functionality, expressed on a scale 0-1, were combined with data on use span and lifespan (or age as a proxy). To calculate measured functionality, the average values of the tested samples were used together with the following assumptions regarding the original performance of the jackets. New jackets resist 20000mm$H_2O$, breathe 17857g/m²/24h and are fully windproof (0mm/s) and water repellent (ISO 5). The breathability results of three jackets were removed due to unreasonably high results e.g. broken fabric. Similarly, the water penetration resistance result of one jacket was removed due to test failure. To plot perceived and assessed functionality, the following rating was used: New=1; Excellent=0.8; Good=0.6; Decent=0.4; Poor=0.2. In addition, since price may be perceived as an indicator of functionality (Rao, 2005; Cooper and Claxton, 2022), price over time was compared to the (other) functionality indicators. In order to do so, price data were normalized to the average original sales price (3942SEK). The components and properties of measured and assessed functionality were weighted equally.

In the few cases of missing age data for secondhand and end-of-life jackets, they were replaced by average values of each jacket group. In the case of price data, data was missing for too many of the jackets in the user survey to be replaced by an average value. These jackets were instead excluded from the analysis of price over time.

## Results

In this section, linear representations and data points of perceived, assessed and measured functionality as well as price over time are presented. First, the focus is on the three main indicators of functionality, then on the properties comprising measured functionality (water penetration resistance, water repellency, breathability and air permeability), and lastly, the comparison is broadened to also include price.

Figure 1 presents perceived, assessed and measured functionality over time. Perceived functionality decreases most rapidly over time

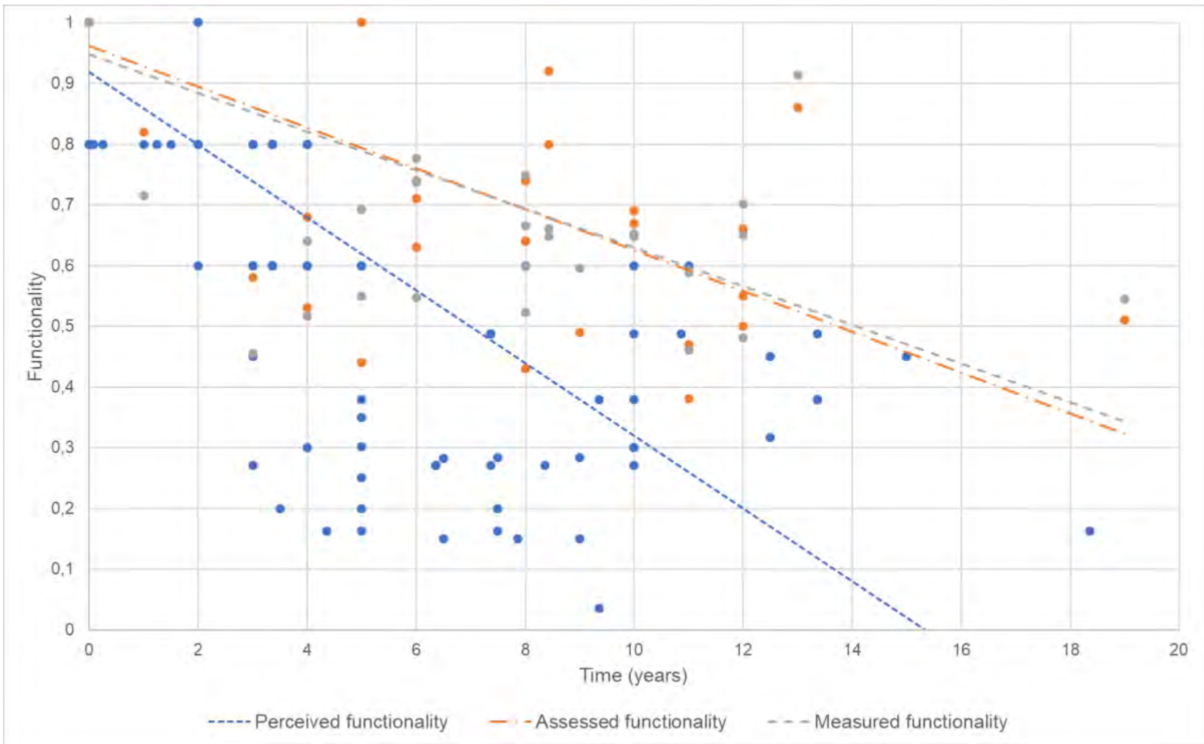

**Figure 1. Perceived, assessed and measured functionality over time.**

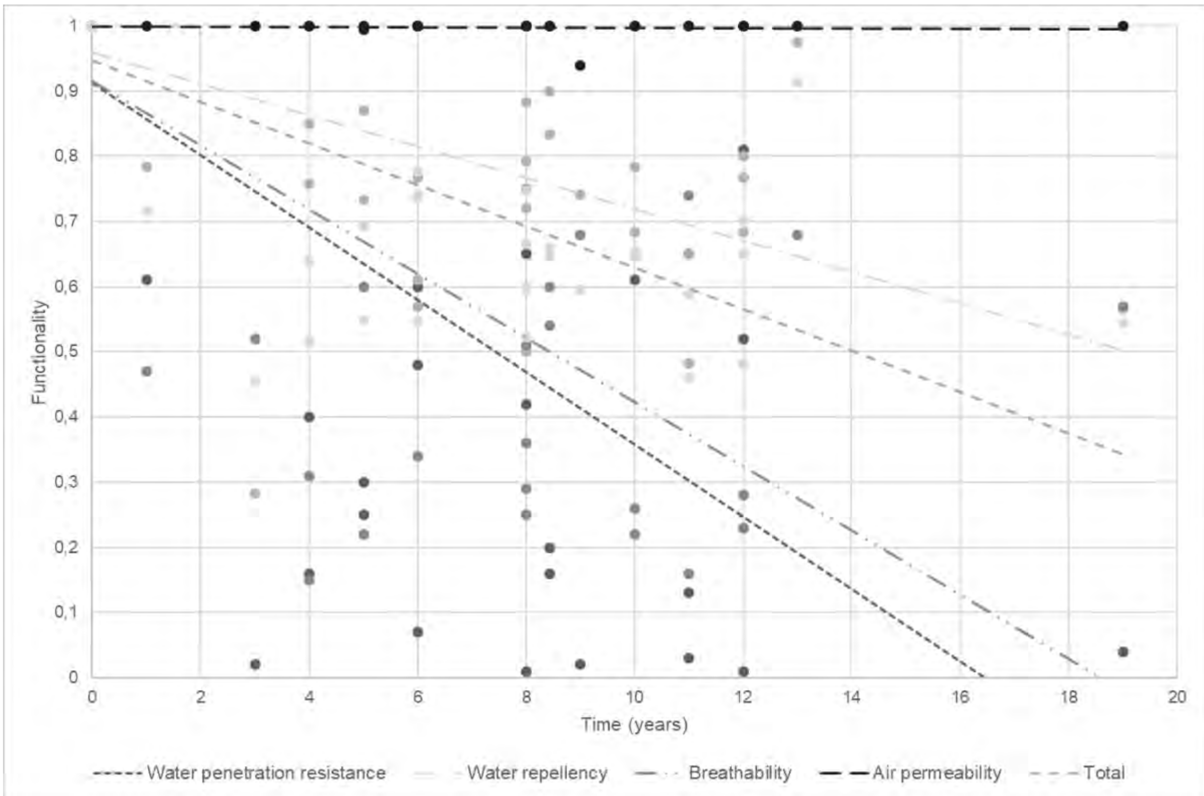

**Figure 2. Measured functionality and the four fabric properties it comprises over time.**

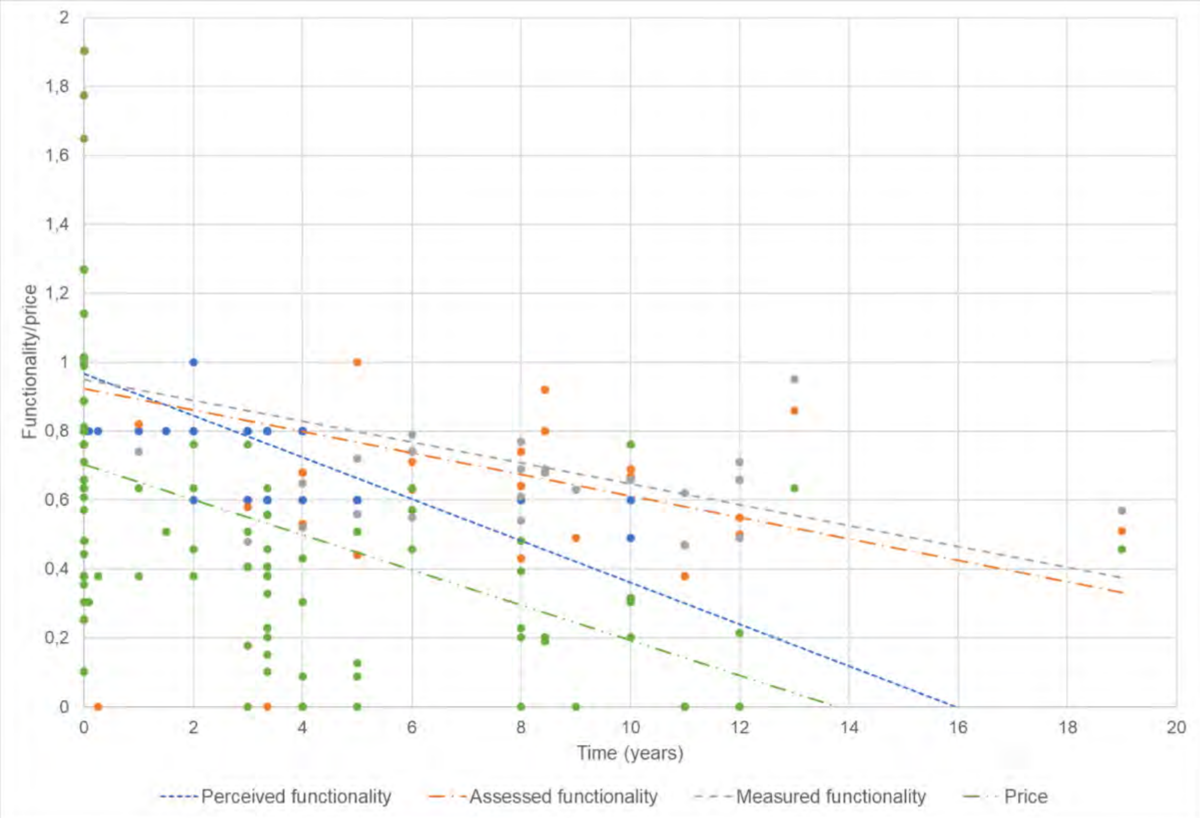

**Figure 3. Perceived, assessed and measured functionality as well as price over time.**

(6% per year) compared to assessed and measured functionality, which correlate and decrease less rapidly over time (around 3% per year).

Figure 2 presents total measured functionality over time, together with the four fabric properties it comprises: water penetration resistance, water repellency, breathability and air permeability. Air permeability does not decrease significantly over time while water repellency decreases around 2.5% per year. Breathability and water penetration resistance decrease most rapidly over time (around 5% per year).

In figure 3, perceived, assessed and measured functionality over time is presented together with price. Price decreases more rapidly over time (around 5% per year) compared to assessed and measured functionality but less rapidly compared to perceived functionality.

## Discussion

Due to the limited sample size of jackets and survey respondents, in turn limited by the total number of shell jackets in the studied secondhand stores, the results of this study are only indicative. The overall pattern of the results, that perceived functionality and price decrease more rapidly than assessed and measured functionality, is however deemed reliable. A larger sample size is expected to increase the robustness of this overall pattern. The choice to use linear representations was made to facilitate comparison between the functionality indicators and thus demonstrate the overall pattern, not to describe data points with high accuracy. Thus, they are not necessarily accurate but nonetheless purposive.

Perceived, assessed and measured functionality of shell jackets are compared in this study even if these functionality indicators do not include the same components and properties of the jackets. Perceived functionality includes all shell jacket components and properties including appearance while assessed functionality includes 14 shell jacket components and measured functionality only includes the fabric. Even if the fabric's original performance is normally stated in the product specification, information could not be found for all jackets. Assumptions were therefore used for original water penetration resistance and breathability. The original breathability assumption of 17857g/m²/24h was based on the average of the available data. The assumption for original water penetration resistance was limited by the test equipment capacity of 20000mm$H_2O$ and the average (25000mm$H_2O$) could therefore not be used. However, the use of 25000mm$H_2O$ as original water penetration resistance would only change measured functionality slightly, decreasing 3.1% instead of 3.2% per year (assuming all test samples that reached the test equipment limit of 20000mm$H_2O$ would reach 25000mm$H_2O$).

The shell jacket components and fabric properties included in assessed and measured functionality were weighted equally. For assessed functionality, it could be argued that the functionality of the front zipper and fabric are more important than e.g. the inner pocket zipper. Since the components related to the fabric were assessed and rated low compared to the other shell jacket components, such a weighting would imply a more rapid deterioration of assessed functionality. Similarly, for measured functionality, it could be argued that water penetration resistance is more important to the overall functionality than breathability. Since water penetration resistance decreases most rapidly over time of the four fabric properties, such a weighting would imply a more rapid deterioration of measured functionality. For perceived functionality, this kind of weighting may be done unconsciously by the user.

The overall pattern of the results, that perceived functionality and price decrease more rapidly than assessed and measured functionality, could partly be explained by the discussed difference in terms of what properties are included in the respective indicators. It is reasonable to conclude that properties included in perceived functionality and price, but excluded in assessed and measured functionality, such as appearance, are influential to this pattern. By extension, user perceptions of such properties as relatively low is probably a relevant motivation for deciding to sell their shell jackets, i.e. a relevant reason for obsolescence. Data collected in the user surveys about the users' motivations to sell their shell jackets reinforce this interpretation (André and Björklund, forthcoming). This points to the potential of producers to adopt design strategies such as timeless design and design for attachment (Van Nes, 2016) to increase the willingness of users to use shell jackets for longer periods of time and thus avoid obsolescence.

Regarding the potential user expectation of price being an indicator of functionality (Rao, 2005; Cooper and Claxton, 2022) the study indicates a closer relationship to perceived, than to assessed and measured functionality. Further, the finding that measured functionality of performance-related properties decreases rather slowly, combined with previous research (Gullstrand Edbring et al., 2016) and survey responses (André and Björklund, forthcoming) indicating that users' concerns about performance are a key barrier to secondhand sales, suggest that providing better information about shell jackets' performance could be effective as a means to increase secondhand sales and thus reverse obsolescence of shell jackets. Future research could investigate the feasibility and effectiveness of implementing a performance-label based on measured or assessed functionality to overcome this barrier and increase secondhand sales.

In addition, in future research it is also relevant to investigate the generalizability of these results. It is likely that concerns about performance is a relevant barrier to secondhand sales of other technical outdoor products such as tents and backpacks. If so, the discussed performance-label could be a relevant measure to reverse obsolescence of such products. However, perceived functionality of such products is hypothesized to be less influenced by subjective properties such as appearance compared to technical clothing products, such as shell jackets. Hence, design strategies to avoid obsolescence such as timeless design could be less relevant for such products.

## Conclusion

To our knowledge, this study is the first investigation of how functionality, as indicated by perceptions, assessments, measurements and price, changes over the course of product lifespans. Perceived functionality and price decline more rapidly than assessed and measured functionality. In other words, secondhand shell jackets seem to be in better condition than users think. This points to the potential of product design and information policy to, respectively, avoid and reverse obsolescence to extend product lifespans of shell jackets and other products with similar characteristics.

## Acknowledgments

This research is supported by the Mistra Sport and Outdoors research and collaboration program, funded by The Swedish Foundation for Strategic Environmental Research (Mistra). We are grateful to colleagues within Mistra Sport and Outdoors for valuable discussions related to the study and to the secondhand and conventional outdoor stores for their willingness to participate.

# Safe and Circular Design - A design method for dealing with substances of concern in products

**Julieta Bolaños Arriola [a], Vrishali Subramanian [b], Conny Bakker [a], Ruud Balkenende[a]**
a) TU Delft, Delft, The Netherlands
b) Leiden University, Leiden, The Netherlands

**Keywords**: Substances of concern; Hazardous substances; Safe and sustainable design; Design method; Circular product design.

**Abstract**: The transition to a circular economy (CE) is challenged by the presence of hazardous substances, also known as substances of concern (SoC), in products. SoC are used in various applications such as electronics, textiles, and toys, and can cause harmful effects on human health and the environment. The topic of SoC in products has been predominantly studied in the fields of chemical engineering and material sciences to develop alternative chemicals and materials. However, methods to safely deal with SoC from the product design perspective are currently limited. This paper aims to address this issue and presents a first version of a Safe and Circular by Design Method. This method supports designers when (re)developing products containing SoC by mitigating or managing the associated risks, resulting in products that last and are safe for the circular economy. The method is based on the results obtained in a previous study on five historical cases of product-substance combinations (IenW, 2022), which identified and classified design strategies to deal with SoC in products. The method involves guiding designers through a comprehensive analysis of the product-SoC combination and its context, considering all stages of the lifecycle(s). The results of the analysis help designers identify action points, informing their decision when selecting and developing mitigation strategies. The method also recommends a list of possible strategies to deal with the SoC. The selected strategies can be qualitatively assessed by the designer to identify their benefits, drawbacks, and tradeoffs.

## Introduction

Any product that potentially harms health or the environment throughout its lifecycle, including multiple use cycles and end-of-life treatments, does not meet the circular economy (CE) principles. To increase the useful life of products, it is imperative that they can be used and reused safely (Alaranta & Turunen, 2021; Bodar et al., 2018).

SoC are present in a variety of consumer products, often without designers and users being aware. Although some SoC are currently regulated to avoid or reduce their presence in specific applications, many others remain in use due to the characteristics or functionality they provide to products. A common example of SoC in products is the use of PFAS (per- and polyfluoroalkyl substances) in food packaging and textiles for their water and oil repellency properties (Holmquist et al., 2016; Schaider et al., 2017). PFAS are ubiquitous and persistent contaminants with a variety of exposure paths, which accumulate in body tissues of humans and animals causing long-term exposure (Krafft & Riess, 2015; OECD, 2013). Some of their known health effects include liver damage, reproductive damage, and thyroid disease (Dickman & Aga, 2022; OECD, 2013). Nevertheless, PFAS continue to be in use in many applications, where safer alternatives do not yet meet similar repellency requirements (Cousins et al., 2019; Hill et al., 2017; Schellenberger et al., 2019). Another example is the use of fluorinated gases as refrigerants and foam blowing agents in cooling equipment (Koronaki et al., 2012; Vuppaladadiyam et al., 2022). Although no significant human health risks are expected from exposure to these gases (except for accidental overexposure), some types of fluorinated gases have ozone depleting properties or may have a high global warming potential (Graziosi et al., 2017; Tsai, 2005; Velders et al., 2015; Vuppaladadiyam et al., 2022). These gases may be released into the environment throughout the lifecycle of refrigerators, generating concerning emissions during the use or during inappropriate treatment and disposal (Ardente et al., 2015; Keri, 2019; McCulloch, 2009).

An informed and better management of SoC in the early stages of the product development process can reduce the hazards and risks posed by SoC. However, awareness, information, and methods for designers to safely deal with SoC in products are currently limited. Our research found that scientific publications concerning safety in a circular economy and the use of SoC in products, predominantly focus on risk management and the development of non-toxic chemicals and material alternatives (E.g., Bodar et al., 2018; Dumée, 2022; Keijer et al., 2019); from the chemical engineering and nanomaterials perspective in particular (E.g., Mech et al., 2022; Sánchez Jiménez et al., 2022) . Other scientific publications center on risk assessment and other methods to measure and analyze the effects of exposure and emissions of SoC (E.g., Harder et al., 2015; Subramanian et al., 2023; Undas et al., 2023). Furthermore, a large number of studies describe cases where SoC represent risks to health and the environment or limitations to the CE, such as: contaminants and plastic recycling (E.g., Brandsma et al., 2022; Leslie et al., 2016) or food packaging materials (E.g., Geueke et al., 2018), amongst others. To the best of our knowledge, no scientific studies address the presence of SoC in products from the product design perspective or provide guidelines for product designers. This paper aims to address this issue, describing the development of a method for designers to deal with SoC in products to mitigate or manage health and environmental risks and make them fit the CE. For this paper, we will be using the classification for SoC shown in Table 1.

| |
|---|
| **A) SoC present in the product – intentionally added to their composition** (e.g., additives such as phthalates in flexible PVC) |
| **B) SoC unintentionally generated by the product – byproducts generated throughout the lifecycle** (e.g., microplastics released from synthetic textiles) |
| **C) SoC used or added temporarily to the material or product for additional functions but not intended to be present in the end product** (e.g., formaldehyde added to textiles during manufacturing to reduce creases, which can remain if not washed before wear) |

**Table 1. Classification of SoC in products, from (IenW, 2022).**

## Method

The Safe and Circular Design method was developed based on a previous study (IenW, 2022), which identified design relevant strategies to deal with SoC in products from five historical cases, as well as approaches to deal with SoC from the industry and other fields, such as green chemistry. The five cases were analyzed through a lifecycle approach, using literature research, Risk Assessment (RA), and Life Cycle Assessment (LCA). These steps were translated into a theoretical first version of a method. Table 2 shows the approach for each of the elements that constitute the Safe and Circular Design Method.

| Safe and Circular by Design Method elements | Approach |
|---|---|
| 1. Analysis of the product-substance combination and emission-exposure scenarios. | The SoC were analyzed through a literature review (including grey literature) to identify their hazards and characteristics and describe where in the lifecycle of the product emissions and exposure occur. |
| 2. Prioritization of emission-exposure scenarios | A qualitative assessment based on the findings of the literature review was done to define emission-exposure scenarios of most concern. Screening RA was used to prioritize the scenarios whenever data was available. |
| 3. Strategy selection – List of possible design strategies | Design relevant strategies were investigated for each case using literature review. The identified strategies were classified into three categories:<br>**Avoid / Eliminate** - Any action that avoids the use of the SoC.<br>**Reduce** – Any action that results in the reduction of the content of the SoC or a reduction of its emissions.<br>**Control / Prevent** – Any action that prevents or controls exposure and emissions of the SoC. |
| 4. Assessment of strategies | The identified strategies were qualitatively assessed by listing benefits, drawbacks, and potential tradeoffs found in literature. Screening RA and LCA were used to assess the effects of the strategies if data was available. |

**Table 2. Approach and development of the elements of the method.**

## Results: The Safe and Circular Design Method

The Safe and Circular Design Method supports designers in dealing with SoC in products; its scope considers the mitigation of SoC through design solutions in the product, as well as related services, or systems. We recommend adopting an iterative approach, until a useful level of detail is obtained (e.g., a feasible strategy to eliminate the substance is identified, or a strategy to reduce emissions is proved effective). The results obtained from the method can be used to steer the development process and facilitate the communication of designers with experts and suppliers. The method is displayed in the form of fillable templates that guide designers through the process and facilitate the collection, analysis, and visualization of information (Figures 2 to 8). Additionally, the method suggests potential sources for the requested information on all the steps of the process. Figure 1 gives an overview of the steps of the method. First, the designer identifies and analyzes SoC and their hazards (Step 1). The designer then identifies where in lifecycle of the product emissions and exposure occur, and which of these scenarios are most concerning (Step 2). The results of this analysis inform the designer's decision when selecting or generating strategies that mitigate the effects of the SoC (Step 3). Finally, the designer assesses alternative strategies, guided by a set of recommendations to qualitatively measure their effects and performance (Step 4).

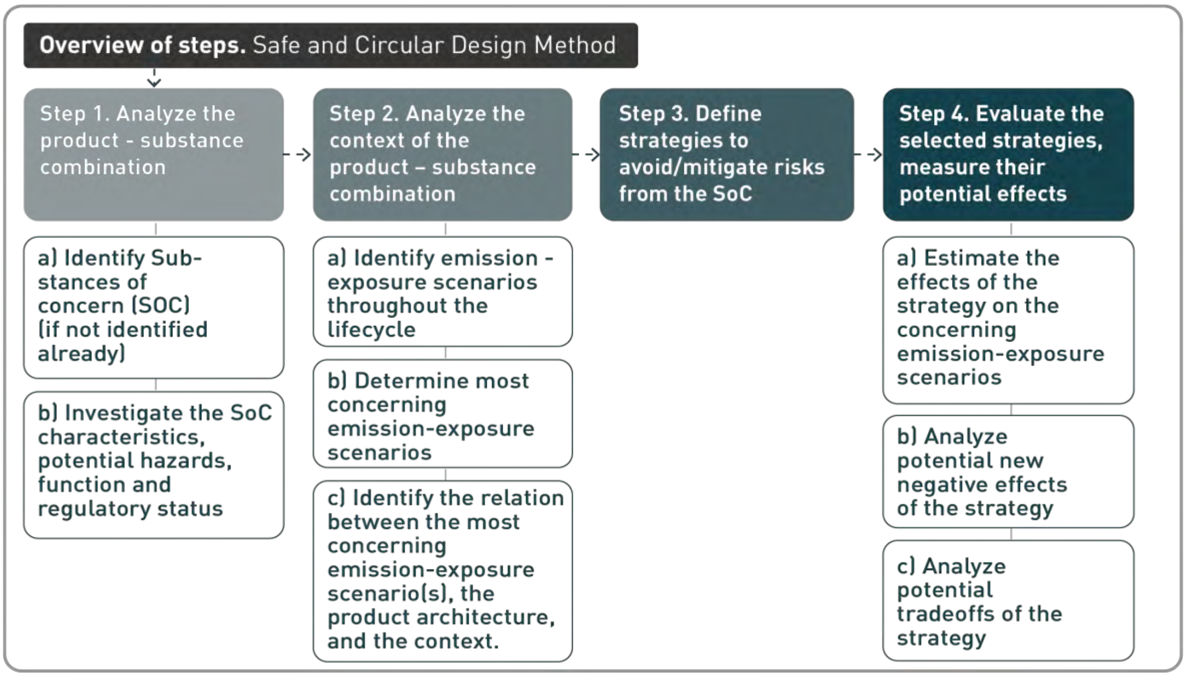

**Figure 1. Overview of steps - Safe and Circular Design Method.**

### *Step 1 - Analysis of the product-substance combination*

a) In cases where the presence of SoC in a product is unknown, the method provides guidance to the designer to identify them. Figure 2 shows the template for this step. The method considers the classification of SoC proposed in Table 1.
b) Once identified, the designer investigates the nature, characteristics, potential hazards, intended function, and regulatory status of each SoC. The method provides a set of questions the designer can follow in the investigation. Figure 3 shows the template for this step with example answers of a case, DEHP (a phthalate-based plasticizer) in vinyl flooring (for illustration purposes).

Step 1. Analyze the product - substance combination

**Step 1a** **Identify SoC (if not identified already)**

Analyze your product for each type of SoC following the recommended actions

| **Typeof SoC** | **Present in the product – intentionally added** | **Generated by the product – byproducts generated throughout their Use/EoL** | **Used or added temporarily to the product for additional functions but not intended to be present in the end- product** |
|---|---|---|---|
| **Recommended actions** | - Obtain a full material declaration of the product and consider all material compositions. | - Briefly reflect on the lifecycle stages of the product. List any substances or bybproducts the product might generate or release that were not intentionally added to its composition. | - Reflect about the production and manufacturing processes of the product. Identify and list any substances that may be added or used during this processes but are not intended to remain in its composition. |
| | - Screen the list and search if the materials and substances are marked as SoC in: ECHA information about chemicals and materials [1], SIN list [2], Material Wise [3], or other resources. | | |

**Figure 2. Step 1a - Identify SoC. [1](European Chemicals Agency, n.d.), [2](ChemSec, n.d.), [3](Chem Forward, n.d.)**

Step 1. Analyze the product - substance combination

**Step 1b** **Investigate the SoC**

Fill in the information to each question on the table, use literature research and the recommendations for possible sources.

| **Question** | **Possible sources** | **Answers** |
|---|---|---|
| 1. What is the SoC? Name(s), type of substance? | ECHA information about chemicals [1], SIN List [2], Material Wise [3] | DEHP or di(2- ethylhexyl) phthalate is a plasticizer. Plasticizers are additives used in plastics to make them flexible. |
| 2. What is the function of the substance in the product? | ECHA Guidance on Information Requirements and Chemical Safety Assessment, Chapter R.12, descriptor list for chemical products category and technical functions [4] | DEHP is used in vinyl flooring to increase, flexibility, dimensional stability, wear resistance, stain resistance, acoustic dampening, and comfort. |
| 3. What kind of hazards does it have on health and the environment? | ECHA information about chemicals [1], SIN List [2], Material Wise [3], scientific studies on health and environmental hazards of the substance | Eendocrine disruption, deformities in the reproductive system, increased risk of premature birth, and cancer. Bioaccumulative and ubiquitous environmental contaminants. |
| 4. How is the substance currently regulated/banned? | ECHA information about chemicals [1], SIN List [2], Material Wise [3] | Banned in the EU since 2021 by the REACH regulation. |
| 5. How much substance is in the product? (If possible and available) | Material declarations from suppliers. Books and manuals on common material compositions. | Varies on the composition of the product depending on the flexibility requirements. |

**Figure 3. Step 1b - Investigate the SoC. Example answers of the case of DEHP in vinyl flooring. [1](European Chemicals Agency, n.d.), [2](ChemSec, n.d.), [3](Chem Forward, n.d.), [4](European Chemicals Agency, 2014)**

*Step 2 – Analysis of the context of the product-substance combination*

a) The designer identifies emission and exposure scenarios for each stage of the lifecycle. In this step the choice of lifecycle stages includes three different end of life pathways (recycling, landfill, and incineration), circular strategies (reuse, recycling, repair, refurbishing, etc.), transportation, collection, and separate production phases, one for materials/chemicals and one for the product manufacturing/assembly. This allows the illustration of a variety of cases. Figure 4 shows the template for this step with example information for the case of DEHP in vinyl flooring (for illustration purposes).

b) The designer qualitatively analyzes the emission-exposure scenarios to prioritize those with concerning emission levels and important environmental and health risks. This is done based on the results of Step 2a, or on additional data obtained from further literature research. The severity of the scenario can be indicated for each of the stages of the lifecycle. Uncertainty can be indicated for those stages where information was unavailable or inconclusive. This is relevant to mark and communicate knowledge gaps. Figure 5 shows the template for this step, with the most concerning emissions-exposure scenarios of the case of DEHP in vinyl flooring.

c) The designer analyzes the relationship between the most concerning emission and exposure scenarios, the architecture of the product, and the context of the product-substance combination. This step is meant to support the designer in identifying design opportunities to eliminate/mitigate the effects of the SoC. Figure 6 shows the template for this step with example information of a case, DEHP in vinyl flooring.

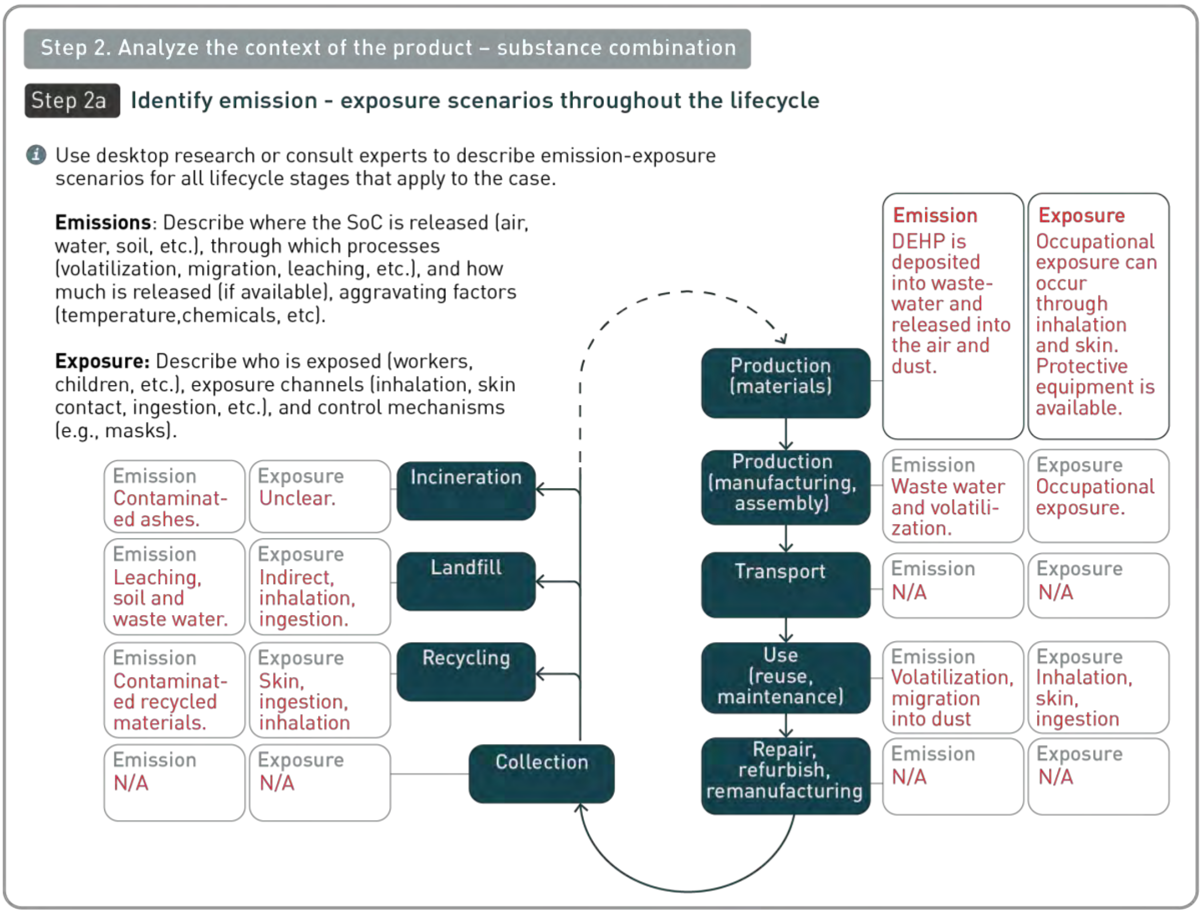

**Figure 4. Step 2a – Identify emission-exposure scenarios per lifecycle stage. Example answers for the case of DEHP in vinyl flooring.**

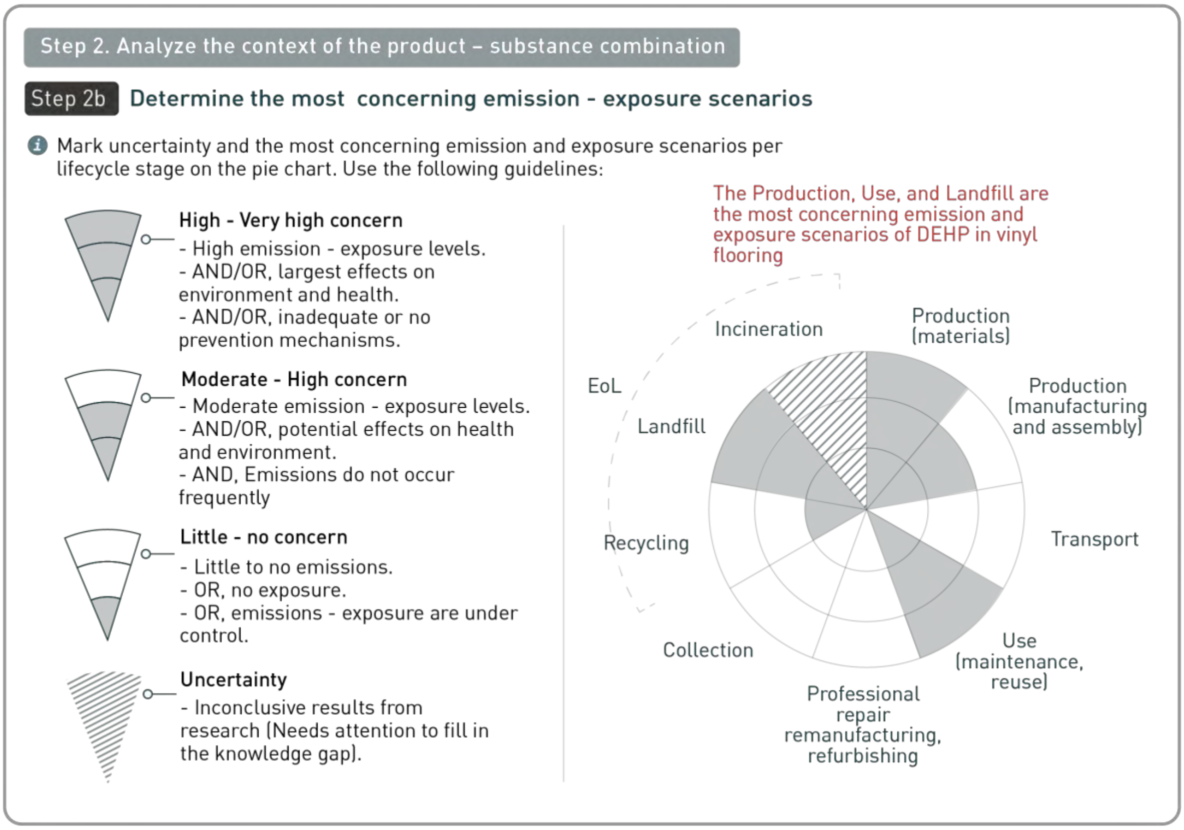

**Figure 5. Step 2b, Prioritize emission and exposure scenarios. Example answer of the case of DEHP in vinyl flooring.**

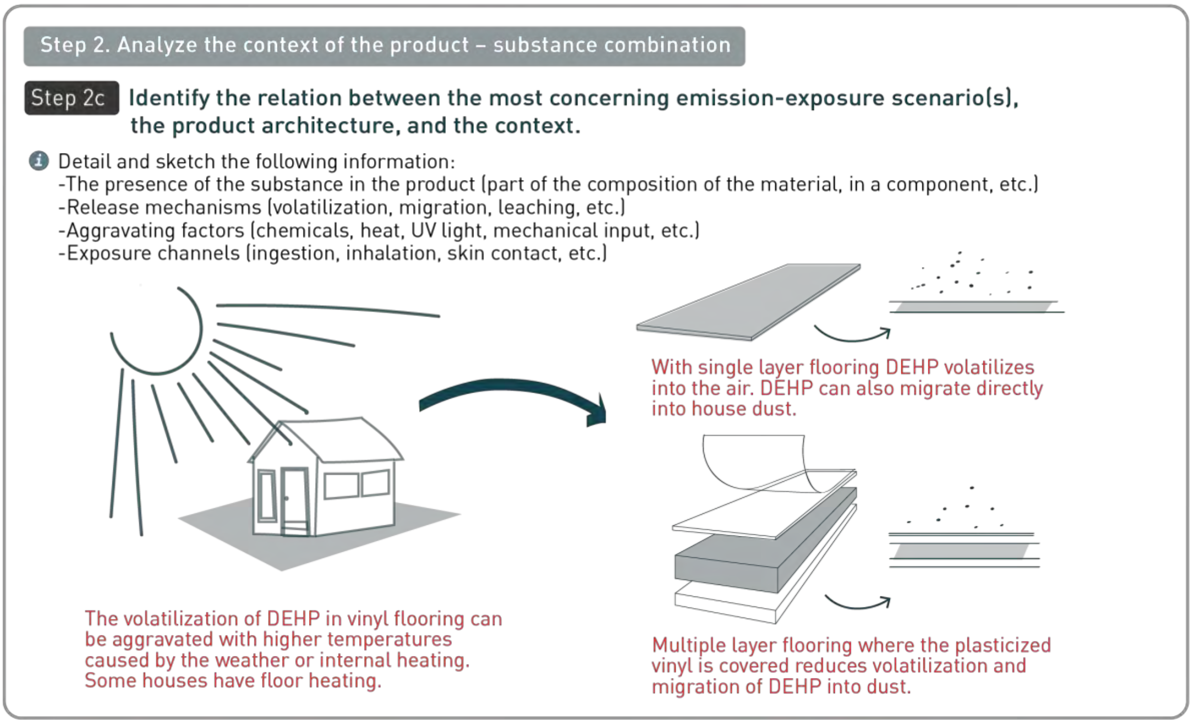

**Figure 6. Step 2c, Identify the relation between concerning emission exposure scenarios, the product architecture, and the context. Example answer of the case of DEHP in vinyl flooring.**

*Step 3 - Selection of strategies*

The method provides a list of possible design strategies for the designer to consider. The method prioritizes strategies to Avoid/Eliminate the use of the substance over Reduce or Prevent/Control strategies (Figure 7).

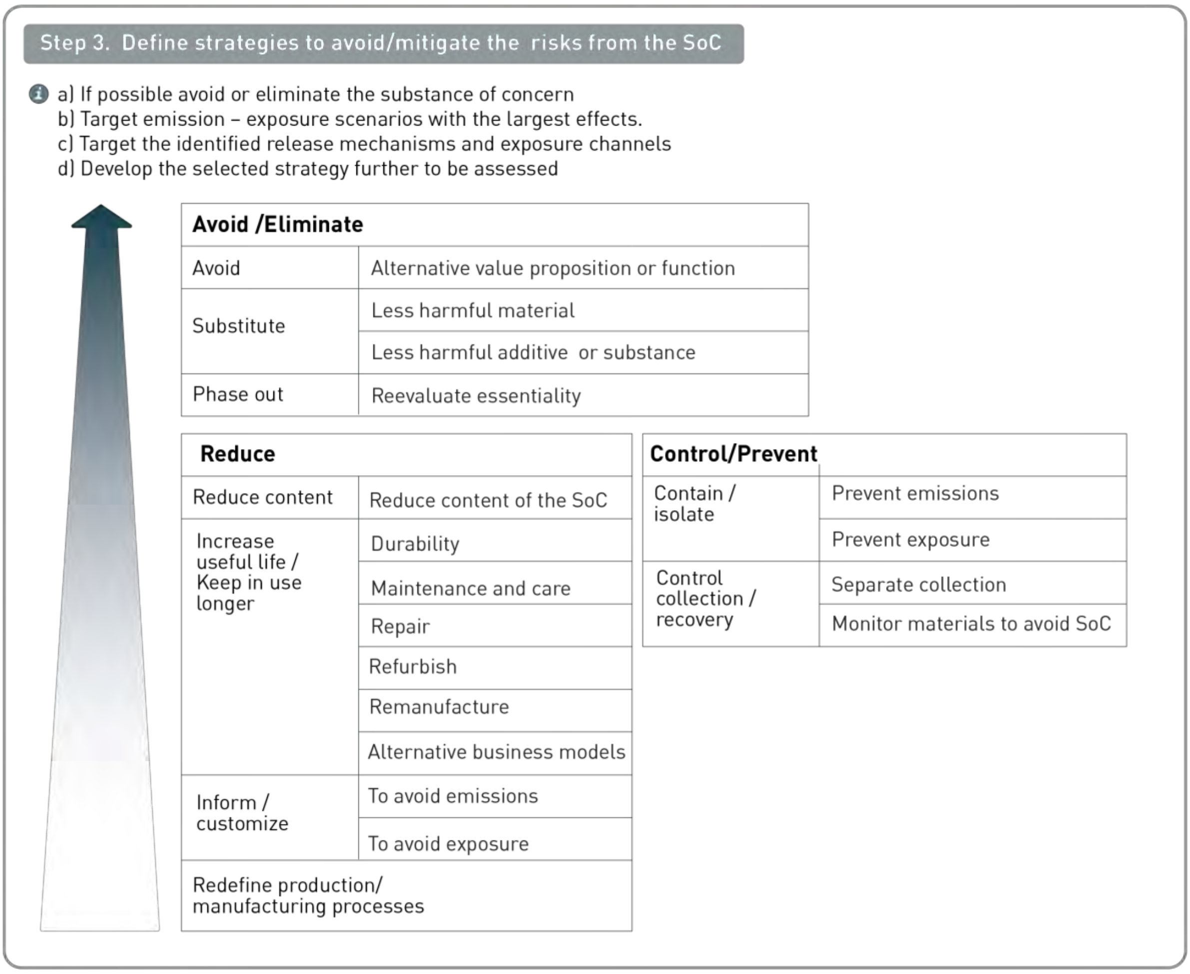

**Figure 7. Step 3, List of possible design strategies to deal with SoC in products.**

*Step 4 - Evaluate the selected strategies*

a) The designer qualitatively estimates if the selected strategy(ies) reduces, maintains, or increases the level of concern of the identified concerning emission-exposure scenarios. This way the designer can observe improvements and further attention points.

b) The designer reflects on the potential negative effects the strategy may have across the lifecycle(s) of the product (e.g., new or increased environmental impacts, new or increased risks).

c) The designer reflects on the potential trade-offs of the strategy, which can include reduced performance, and increased manufacturing costs amongst other.

Figure 8 shows the template for Step 4 with example information of the evaluation of a strategy to reduce emissions of DEHP from vinyl flooring.

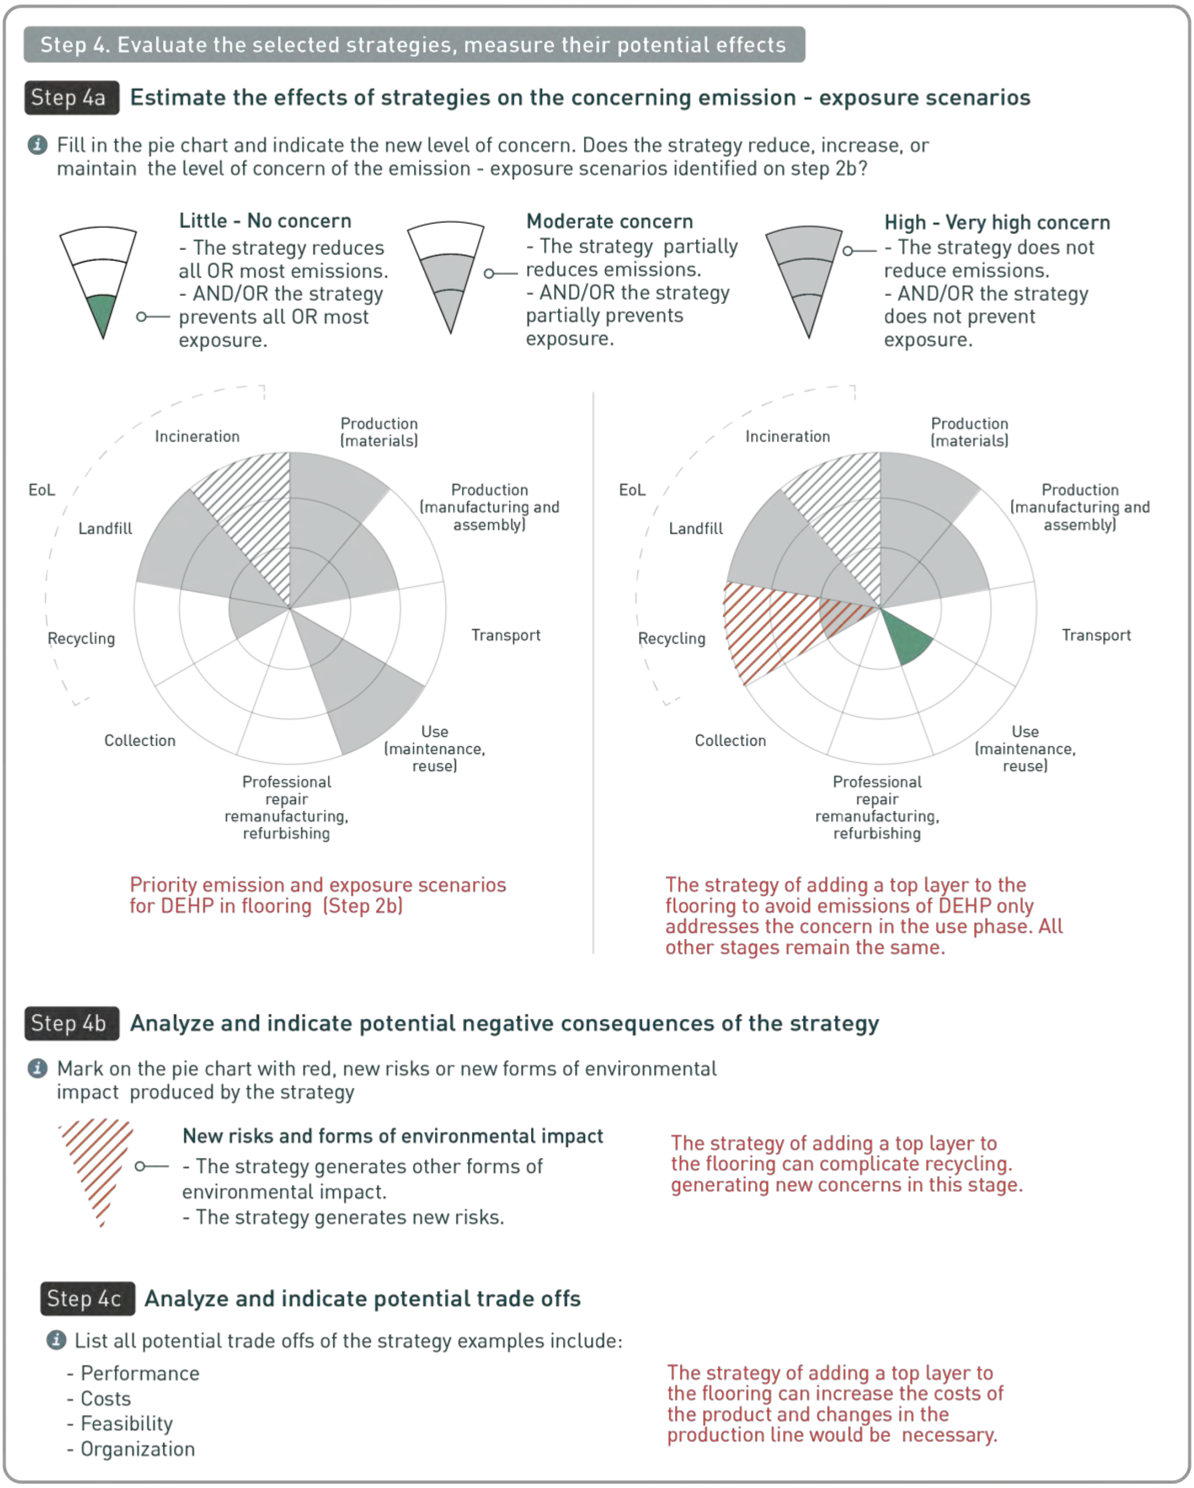

**Figure 8. Step 4, Evaluation of selected design strategies. Example answer of the case of DEHP in vinyl flooring.**

## Discussion and Conclusion

This study aimed to develop a method to address the presence of SoC in products from the product design perspective. The result is a first iteration of the Safe and Circular Design Method, which was developed based on the analysis of five historical cases of product-substance combinations where design-relevant strategies to mitigate the effects of SoC were identified (IenW, 2022).

Currently, the presence of SoC in products is mainly addressed from a chemicals and materials perspective, by both the industry and regulatory bodies. Due to this, strategies are often limited to substitution, which may cause unintended, often unknown consequences, such as: similar or new risks, new forms of environmental impact, or tradeoffs, including performance loss or increased costs. Furthermore, in some cases, alternatives that meet equal functional requirements do not yet exist or are technically impossible, which causes the hazardous substance to remain in use. By approaching SoC in this manner, potential negative effects throughout the lifecycle(s) of products can be overlooked, and alternative strategies become limited.

Although possible design strategies were derived from the investigation of the case studies, we have no indication that these were carried out by manufacturers intentionally through a design perspective. Additionally, we found a few successful examples where the importance of following a systemic (holistic) approach is evident, such as the case of refrigerants in cooling equipment, where substitution with less harmful gases has been combined with hermetic systems in the product, collection systems, and recycling processes that prevent emissions. We have therefore developed a process through which designers can partake in the mitigation of risks caused by SoC through a systemic approach which makes possible tradeoffs and unintended side effects visible. By using this method, designers can consider multiple layers (product-substance combination, its context, users, lifecycle), and a larger variety of strategies.

Since the current version of the method was derived theoretically from the investigation of the five cases, it will need to be tested by design practitioners to evaluate its usability, workflow, and performance. We have identified several aspects to be considered in next iterations of the method. First, we observed challenges when collecting the necessary data for the analysis of the product-substance combination, its emission and exposure scenarios, and effects of potential strategies. Following iterations of the method will have to provide further insights on data sourcing and dealing with uncertainty. Additionally, the method is currently largely based on qualitative analysis, which can lead to uncertainty in establishing priority emission and exposure scenarios and determining the effects of alternative strategies. While qualitative analysis provides a first estimation, the integration of quantitative methods such as Risk Assessment and Life Cycle Assessment will deliver more accurate results. However, these require large amounts of data and may not be a part of the skills of a designer, highlighting the importance of collaboration with environmental scientists. Furthermore, future developments should explicitly address how to deal with tradeoffs, newfound risks, and environmental impacts of new strategies. Similarly, ethical considerations, such as balancing performance losses with safety concerns and environmental impacts, need to be specifically addressed. Finally, the method was originally intended to be applied in early stages of the development process. However, it now appears to be more suitable for redesign assignments. Therefore, the integration of this method as part of the development process of new products needs to be further considered.

# Consumers' concern about chemicals in clothing – Environment, skin contact, and the materiality of colour

**Minna Autio**[a,b], **Janne Poikolainen**[a], **Sanna Sekki**[a], **Lotta Ruippo**[a], **Riikka Räisänen**[a,b]
a) The Department of Education, Helsinki, University of Helsinki. Finland
b) Helsinki Institute of Sustainability Science HELSUS, University of Helsinki, Finland

**Keywords**: Colour; Consumer; Clothing; Materiality; Sustainability.

**Abstract**: When studying the meanings of colours, prior consumer research has focused mainly on the visual perspective, typically ignoring the material side of colour (i.e. colour as a physical and chemical substance). This has also led to frequent ignorance of health, safety, and environment (HSE) issues related to the production and use of colours. Our study focuses on consumers' perceptions of the HSE aspects of colours in clothes, with an emphasis on both synthetic and bio-based colourants. The data of the study consists of semi-structured thematic interviews with Finnish consumers (n=27). Using data-driven qualitative analysis, we examine how consumers view the difference between synthetic and bio-based colours (i.e. colourants) in relation to ecological sustainability. In addition, we study how they perceive colour-related health and safety aspects in clothing. Our findings suggest that consumers picture natural colourants as ecological, whereas synthetic dyes are perceived to be ecologically unsustainable. Consumers typically encounter the material aspect of colours when the colour behaves in an unexpected way during use or maintenance. This may also make them aware of potential health issues related to dyes. Interestingly, this concern was brought out in the context of both naturally and synthetically coloured products.

## Introduction

Colours shape the everyday experiences and practices of consumers in various ways. They guide what we eat, what kind of clothes we wear, and how we decorate our homes (Yusuf et al., 2017). So far, the meanings of colours in the everyday lives of consumers have mainly been studied from a visual perspective and in relation to specific products and brand images (e.g. Aslam, 2006; Bobrie, 2018). Meanwhile, the discourses of consumer studies have mostly ignored the discussion on the material dimension of colours (i.e. colour as physical and chemical substance). This has resulted in the inability of these discourses to recognise and address the issues of health, safety, and environment (HSE) in relation to the production and consumption of colours. In this paper, we will make these issues the focus of our discussion, approaching them from the perspective of consumers and investigating their perceptions of the HSE aspects of colourants in clothing.

The current production of clothes is characterised by the over-consumption of natural resources and complex environmental impacts. The textile industry – which includes clothing production – is the second most polluting industrial sector in the world, topped only by the oil industry (Chen et al., 2021). As Carvalho and Santos (2015) note, the spinning, weaving, and industrial production of textiles are associated with the use of non-renewable energy and production of waste. Furthermore, related finishing processes, such as dyeing, consume remarkable amounts of water and chemicals. The use of colourants in textile and clothing production also harms waterways (Al-Tohamy et al., 2022) – in fact, dyeing in textile processing is now considered one of the major aquatic polluters (Mehra et al., 2021). In addition to the environmental burden, the textile and clothing industry is often associated with poor working conditions (Carvalho & Santos, 2015) and health problems (e.g. respiratory issues) among workers (Manzoor & Sharma, 2020).

Previous research has indicated that consumers are increasingly interested in HSE aspects of consumption (e.g. Sax & Doran 2016; Sajinčič et al., 2021). The main concerns among Europeans (EU-28) are air and water pollution, waste generation, and the impact of chemicals on health (Luca et al., 2018). According to Hartmann and Klaschka (2017), consumers are concerned about unhealthy chemicals in consumer products, particularly in relation to products that make direct contact with the human body (e.g. textiles). However, consumers' perception of colours (i.e. colourants) as a potential cause of health problems and ecological harm is still a largely unmapped area of study (however, see Geissler, 2009; Yli-Heikkilä et al., 2020; Kamboj & Mahajan, 2017). In this paper, we aim to bridge this knowledge gap by studying Finnish consumers' perceptions of HSE aspects of colours in the context of the production and consumption of clothes. The subject is approached particularly from the point of view of the perceived differences between synthetic and bio-based colourants.

## Synthetic and natural colourants in clothing – Towards the perspective of the consumer

Current colour production within the clothing industry is built on synthetic colour culture, mainly using synthetic colourants produced from non-renewable materials. More eco-friendly natural dyes, with plant, animal, or mineral origins (Kumar Gupta, 2020), are still not commonly in use within the industry, as the commercial business has offered only small-scale niches for naturally dyed garments (Geissler, 2009). This is partly due to certain limitations, such as the less versatile colour palette, limited fastness, and less competitive production costs of bio-based colourants (Geissler, 2009; Jihad, 2014; Kumar Gupta, 2020). However, as Yusuf et al. (2017) have noted, natural dyeing is gradually making its way into the global market, thus helping to reduce the environmental load caused by synthetic dyes (see also Haji & Naebe, 2020; Kumar Gupta, 2020).

Consumers value products made from bio-based resources (e.g. Morone et al., 2021), and the term 'bio-based' is largely associated with positive environmental aspects, such as 'naturalness' and 'environmental friendliness' (Sijtsema et al., 2016). The importance of the sustainability perspective also becomes manifest in consumer interest in, and valuation of, organic products – for example, textiles made of organic cotton (Hustvedt & Dickson, 2009). Similar interests have been identified in consumer perceptions of the colourants used in apparel. For example, consumers may wonder whether the dyes used in textiles are harmful to the environment and human health (Yli-Heikkilä et al., 2020).

Although the topic is still mostly unstudied, consumers' views of bio-based dyes in clothing have gained some prior scholarly interest. According to Geissler (2009) and Kamboj and Mahajan (2017), natural dyes represent responsible and ecological choices for consumers. Geissler's (2009) study showed that consumers view naturally dyed textiles as something special and exclusive. They also associate natural dyes with the natural environment, ecological awareness, responsibility, and fairness. On the other hand, consumers are concerned about the fastness of natural colours. Geissler's findings indicate that consumers believe that plant-derived colourants are less stable, making textiles lose colour during use and washing. The same study also touched on the health-related aspects of colourants, indicating that some consumers are worried about possible allergic reactions caused by natural dyes.

In a more recent study, Kamboj and Mahajan (2017) stated that consumers perceive naturally dyed products as renewable and safe for human skin. In this sense, their results were partly in contrast to the health concerns identified by Geissler (2009). Moreover, the study of Kamboj and Mahajan revealed a belief that wearing naturally dyed clothes provides the wearer with an image of being a green and conscious consumer. These results were later supported by the studies of Landim Neves et al. (2019) and Yli-Heikkilä et al. (2020). The former shows that consumers associate naturally dyed products with safety and high quality, whereas the latter indicates that consumers link synthetic colourants with the chemical industry, harmfulness, toxicity, and artificiality.

## Data and methods

Our study is based on semi-structured thematic interviews (Gaskell, 2000) of Finnish consumers conducted in 2020 and 2021. The interviewees (n=27) were recruited using the snowball method – that is, by asking the initial interviewees to name other potential interviewees from their own social networks

(Creswell 2013). The interviewees were informed about the purpose of the study and the focal themes of the interviews during the recruitment process. Written informed consent was obtained from all participants before the interviews.

The ages of the interviewees ranged from 24 to 73 years. Seven of them were men, and twenty were women. Six interviewees had prior knowledge about and/or experience with textile colourants and dyeing with natural colourants. The interviewees were interviewed either individually or in small groups. The interviews took from 21 to 61 minutes and were transcribed later. The main themes of the interviews included the consumption of clothes, sustainability aspects related to clothing, and clothing maintenance. The interviewees' views on the origin of colourants, as well as their thoughts about naturally dyed textiles, were also discussed. The data was analysed by using data-driven qualitative content analysis.

## Consumers' perceptions of colourants in clothing: environmental aspects

Prior colour research (e.g. Bobrie, 2018; Yusuf et al., 2017) suggests that consumers' interest in garments is guided primarily by the appearance of the products, whereas the origin of the colourant is typically a criterion of much smaller importance – if considered at all. Our data suggests that this ignorance may be partly due to the unawareness about the HSE aspects of colourants, as in here:

> I guess the [public] discussion has focused more on fibres and human rights. On the aspects that have to do with the material. I haven't really thought about the colours that much. But I guess there are many problems involved with them, too, of which the consumer should be more aware. (Female, 31 years)

The discourse represented by the quote implies that consumers perceive colours primarily from a visual point of view without necessarily recognising their material dimension related to the use of colourants. This may also explain the general tendency to not consider colours as something with potential HSE impacts. On the other hand, the interviews imply that consumers are able to critically discuss and reflect on the origin of colours after becoming aware of the questions related to the subject. This competence was supported by prior knowledge of environmental and ethical issues concerning clothing production, with this understanding providing a framework for the discussion of colour production as well.

As argued above, bio-based products are often associated with positive HSE aspects (see also Sax & Doran, 2016). This also became evident in our study: when consumers were encouraged to discuss the origin of colourants, or synthetic and natural colours, their associations were juxtaposed, as consumers discussed 'bad' (synthetic) and 'good' (bio-based) colour properties:

> I have a strong feeling that [synthetic colourants] are somehow intense and artificial. Harmful. (Female, 25 years)

> A plant is a more natural or kind of a safer product, or however you should phrase that. (Female, 28 years)

Overall, the interviewees' thinking was characterised by divided perceptions of ecologically sustainable natural colourants and unsustainable artificial dyes, reflecting consumer appreciation of ecological materials and products (see also Geissler, 2009; Sijtsema et al., 2016).

## The skin contact of colours: The perspectives of safety and personal health

Products with either external or internal direct contact with the human body are apt to raise health concerns in consumers (e.g. Hartmann & Klaschka, 2017; Sax & Doran, 2016). Such concerns are also evident in our data, manifesting in the interviewees' pondering of the potential health effects of the colours they wear. Their concern was primarily connected to the personal safety of the consumer, whereas the related health and safety risks within the production process (e.g. dyers' exposure to harmful chemicals) were not discussed, at least not explicitly.

In scholarly discourse, it is common to depict bio-based dyes as non-toxic, non-allergenic, and non-hazardous alternatives to more harmful synthetic colourants (e.g. Jihad, 2014; Kumar Gupta, 2020). However, our data implies that even though consumers also often view natural dyes as the safer option, they do not necessarily consider naturally dyed clothes free from negative health impacts (see also Geissler, 2009). A 67-year-old craft enthusiast, for example, referred to both natural and synthetic colourants as potential causes of allergic reactions:

> Well, those [natural dyes] are no better; they can truly be allergenic. Yes, I have learnt to watch out for both [natural and synthetic dyes]. (Female, 67 years)

A typical situation in which consumers encounter the material aspect of colourants in their everyday lives is when colours do not behave as expected – for example, during maintenance. This may also raise questions about the possible health effects of colourants. The interviewee found herself in such a situation after her (synthetically dyed) training jacket emitted colour during the wash:

> It does not bother me that much if the colour changes or fades. What troubles me is that colour bleeding occurs even after many washes. And if it's, for example, raining outside, and you hang the laundry out to dry, there will soon be a pink puddle. So, [I'm pondering] the safety aspect; the jacket releases colour while jogging, and the colour gets on the skin. (Female, 24 years)

Overall, the safety of the colours in clothing appeared in the interviews as a relevant question for consumers – at least after the interviewees became aware of the issue. What made this aspect particularly noteworthy from the consumer's point of view was the direct skin contact with the cloth and the potential risks related to it:

> I think skin contact plays a pretty big role when it comes to clothes. If it can be assured that there are no chemicals that can dissolve into the body, it's a positive thing. (Male, 40 years)

References to the cruciality of skin contact were made in several different contexts during the interviews. Textile finishing agents, and the risk of allergic reactions caused by them, was one such occasion. Moreover, health concerns were considered particularly relevant regarding children and their health, as an interviewee explained: 'Well, these days, you can't put any clothes on small children without washing them first' (Female, 62 years). In such situations, an attractive garment may turn, at least partially, into a health and safety risk.

## Conclusions

Consumer research has approached the meanings and properties of colours mostly from a visual perspective (e.g. Aslam, 2006; Bobrie, 2018). Less attention has been given to the material aspects of colour or to consumers' perceptions of them. This also includes the health, safety, and environmental (HSE) impacts of colour production and coloured products. The current colour palette of clothes is produced primarily with synthetic dyes, which harm human health and the environment. Previous research has shown that consumers are concerned about the (un)healthiness of chemicals in consumer products, especially when the products come into direct contact with the human body (e.g. Hartmann & Klaschka, 2017). Prior findings also show that consumers value bio-based and ecological products (e.g. Sijtsema et al., 2016). However, these attitudes and valuations have only rarely been discussed in relation to colours in consumer products.

Our study focused on consumers' perceptions of HSE aspects of colours in the context of clothing. The subject was approached particularly from the perspective of perceived differences between synthetically and naturally dyed clothes. During the interviews, consumers associated natural dyes with naturalness and ecological sustainability, whereas synthetic dyes were connected with artificiality and environmental burden. On the level of health and safety, the distinction appeared less clear and obvious. While the interviewees associated synthetic dyes more directly with health risks, concerns about natural dyes as a potential cause of allergic reactions were also pointed out.

On the other hand, our study indicates that in order for consumers to reflect critically on the

HSE aspects of colours, they first have to be made aware of the materiality of colours. To some degree, this awareness may arise as a result of everyday situations in which colours do not behave as expected – for example, when a garment bleeds colour. Such situations force consumers to confront the physical and chemical side of colours, potentially raising concerns about the colourants' safety. However, from the point of view of sustainability, it is important to make HSE issues a topic of a more comprehensive interest – an interest that also extends beyond the sphere of the personal and takes ecological and ethical issues related to production into account. This requires an active effort to make the materiality of colour a subject of public discussion.

# Circular economy in critical value chains: the case of hydrogen electrolysers and fuel cells

**Marie Axt[(a)], Brian Baldassarre[(a, b)], Julian Kirchherr[(a)], Jakob Vestergaard[(a)]**
a) Roskilde University, Roskilde, Denmark
b) Joint Research Centre of the European Commission, Seville, Spain

**Keywords**: Critical raw materials; circular economy; value chain analysis; strategic autonomy; recycling; renewable energy.

**Abstract**: Green hydrogen is likely to play a central role in the European Union's (EU) energy transition due to its potential as a low-emission energy source and storage medium. To achieve a meaningful role for hydrogen in the European economy, a large scale-up of the relevant technology is required. Due to the technology's high dependency of critical raw materials, this poses a risk of future supply chain bottlenecks that EU policymakers seeks to address. The circular economy (CE) aims to promote sustainable economic growth by reducing resource use and waste. With its focus on the principles of reuse, reduce and recycle, it is well positioned to help solve for the challenge of critical raw materials. This research aims to provide clarity on specific CE strategies applicable to fuel cell and hydrogen (FCH) technology supply chains and what drives or hinders their adoption. Using a mixed methods approach of literature and practice review and qualitative expert interviews, we define four exemplary drivers and barriers along de Jesus and Mendonca's (2018) framework of CE drivers and barriers. In doing so, this study contributes to the better understanding of circularity strategies and their determinants in general, as well as provide practical insights for policymakers and businesses on matters of future relevance for FCH technologies specifically. Our research is ongoing to further refine and extend our results.

## Research Background and objective

To limit global warming, societies must rapidly transition to a carbon-neutral energy system. Hydrogen is a chemical element that can be used as an alternative energy carrier and storage medium, and widely considered a key solution to decarbonise the economy (European Commission (EC), 2021). 'Green' hydrogen is generated from renewable electricity through electrolysis. As fuel, it can be used for on-demand direct electrification in carbon-intensive sectors, such as energy-heavy industry, residential heating, or long-range transport (Hydrogen Council, 2017). To produce and use hydrogen in such a way, two key technologies are required: fuel cells and electrolysers. Electrolysers generate hydrogen from water using electricity, while fuel cells reverse the process and provide electricity from hydrogen. Their production is therefore essential for the European energy transition.

Different types of electrolysers/fuel cells exist. They are in different stages of maturity and require diverse material inputs. Some of these materials, such as platinum group metals (PGM), titanium, and nickel are considered 'critical' by the EU since there have high supply risks due to import dependencies, significant economic importance and a lack of viable substitutes (EC, 2020a; IEA, 2020). For example, South Africa and Russia account for 90% (70% and 20% respectively) of PGM production, making this a highly concentrated market with limited substitution potential (CRM Alliance, 2023). While considering different FCH technologies during our research, our results focus on proton membrane exchange (PEM) electrolysers and fuel cells because the critical raw material challenge is most pronounced for this type.

As the EU seeks to reduce its dependencies for key strategic assets and therefore strengthen its strategic autonomy [1], it aims to make

[1] Strategic autonomy describes "the ability to set one's own priorities and make one's own decisions in matters of foreign policy and security, together with the institutional, political and material wherewithal to carry these through"

hydrogen technology supply chains more resilient. This paper seeks to explore the potential contribution circular

economy strategies can have to this end. The circular economy is “an economic system that replaces the ‘end-of-life’ concept with reducing, alternatively reusing, recycling, and recovering materials in production/distribution and consumption processes” (Kirchherr et al., 2017, p. 229) and can be applied to supply chains through reducing material inputs, reusing components and products, and recycling materials (EC 2020b). A CE approach therefore might be well positioned to enhance the EU’s strategic autonomy while at the same time also contribute to sustainable practices in the sector. As both circularity and strategic autonomy are simultaneous aims of EU industrial policy, meeting both ends through one strategy would be highly attractive for policymaking.

The CE literature is increasingly focusing on studying the implementation of CE strategies, or the lack thereof (Lieder and Rashid, 2016). In that context, de Jesus and Mendonca (2018) developed a framework to categorise relevant drivers and barriers along economic, technical, cultural, and regulatory dimensions. Such studies have been conducted for various supply chains (e.g. Kumar et al, 2021; Baldassarre et al, 2022) and for the European economy in general (Kirchherr et al, 2018), but not yet for fuel cell and hydrogen (FCH) technologies. A small body of academic literature and multiple reports on hydrogen have assessed the circularity potential for such supply chains (e.g. Bareiß et al., 2019; EC, 2020a; IRENA, 2020; Lotric et al, 2020; Kiemel et al, 2021; IEA, 2022, World Bank and Hydrogen Council, 2022). They reach the conclusion that current research efforts focus on the reduction of primary material inputs, especially for platinum group metals (PGM) as they are expensive and critical (Bareiß et al, 2019; IEA, 2022). Recycling and reuse strategies are featured less prominently, through are considered feasible. Different sub-components of FCH products have different lifetimes and can therefore be reused or repaired/recoated to extend product lifetimes (Lotric et al, 2020; de Nora, 2023). For recycling, multiple chemical and mechanical processes can be applied to recover materials (Valente et al, 2018). Though they are not yet applied widely, recovery rates of 50-75% for PGMs and higher for other materials are possible (Lotric et al, 2020). Studies modelling the future demand of critical raw materials and potential supply bottlenecks assume substantial recycling rates for FCH products but also highlight their dependencies on other factors, such as material prices and advances in material efficiency (Rasmussen et al, 2019; IRENA, 2020).

While initial work has been conducted on the circular strategies relevant for the FCH technology value chain, the knowledge is often highly technical and fragmented. Furthermore, its implementation faces numerous challenges, especially reusing and recycling of products (Quilez et al, 2017). A holistic consideration of applicable strategies along the value chain as well as what drives or hinders their implementation is currently lacking. Our research aims to shed light on this matter by mapping the FCH technology value chain and applicable CE strategies, and defining drivers and barriers to their adoption.

In doing so, we contribute to the generation of theoretical knowledge on CE implementation, potentially inform business practices, and provide guidance for policymakers regarding the required support for the sustainable and resilient governance of those supply chains. Our work furthermore contributes to the literature body on EU industrial policy and mission-oriented innovation policy.

The remainder of this paper describes the methodological approach of our research; the results of the value chain mapping with four exemplary drivers and barriers; and a conclusion.

## Method

The objective of this paper is to address the knowledge gap on circularity in the European hydrogen technology value chain and define the relevant drivers and barriers to their adoption. The two central results are a visual representation of the value chain and identified circularity potentials, and the description of

(Lippert et al., 2019, p.5). The concept has been adapted by the EU as ‘open strategic autonomy’ to also signal its commitment to free trade (European Parliament, 2022).

exemplary drivers and barriers to their adoption. The method to address the research objective followed several steps along three phases (figure 1):

(1) data collection using publicly available materials;
(2) data collection through expert and stakeholder interviews; and
(3) data analysis and coding of results.

This paper is based on the results of the initial phase of data sampling and will be further developed over the next months as our collected data substantiates.

For the supply chain mapping, we collected the available information from publicly available studies, reports, and company websites to develop an initial visualisation of the FCH technology value chain in Europe. The reports were all published in the past five years by reputable institutions such as the European Commission, the International Energy Agency, the World Bank, the Hydrogen Council or EU funded projects such as HyTechCycling. Based on these sources, we also curated an initial list of applicable circularity strategies.

In the second phase we conducted semi-structured interviews with experts from policymaking, academia, and industry to validate the supply chain mapping, discuss circularity potentials and identify drivers and barriers. The interview guide was developed based on the identified open questions from phase 1 and iteratively tested with some of the experts interviewed. The interviewees were identified and pre-selected based on their professional affiliation. We aim to cover a broad range of backgrounds/employers to include multiple perspectives from various stakeholders. We furthermore ask each interview partner whether they can recommend further experts to us based on a snowball sampling approach (Handcock & Gile, 2011). This allows us to further contact individuals we did not identify during the first pre-selection step. So far, a total of 8 interviews were conducted, representing private and public stakeholders (see table 1). Written notes were taken during the interviews.

During the third phase, interview notes were synthesised, systematised, and analysed according to an axial coding framework. Statements were clustered and synthesised according to main themes and attributed to the relevant stages of the value chain. By following this approach, both inductive and deductive reasoning are used to reach our results (Miles et al., 2013). The mapping was further refined with the obtained insights. The identified drivers and barriers are then attributed to the four categories defined by de Jesus and Mendonca (2018) (cultural, regulatory, economic, and technical drivers and barriers) and discussed.

## Results

*Value chain description*

Figure 2 visualises the value chain of PEM electrolysers and fuel cells in a simplified version. As the value chain is fragmented and complex, a simplification is required to allow for generalised insights and use the visualisation in discussions with stakeholders. Through different colours, the different circularity potentials (reduce, reuse, repair and recycle) are indicated, though some currently visualise more the hypothetical potential than actual practices. Along the value chain, several CE strategies are applicable: material efficiency enhancements reduce the requirements for material inputs; individual components and stacks can be repaired or replaced without exchanging entire products (depending on product design) and at the end of life, materials can be recovered through recycling. Some strategies are more firmly anchored in the hydrogen sector today than others.

Starting from raw and processed materials, chemical companies and other specialised producers process those into key components such as membranes, catalysts, electrodes, and all other components. The components are assembled into cells and stacks by FCH OEMs. In some instances, OEMs are also the producers of all or some sub-components. As the market is fragmented and many FCH OEMs are small companies or start-ups, chemical companies and raw material traders hold substantial market power.

The complete electrolyser/fuel cell is then sold to energy companies or other customers for deployment for the production and use of hydrogen. Several OEMs offer guarantees and after-services, mending products as required [D, H]. However, due to the small market, this is not yet firmly established and professionalised [D]. Some companies also offer repair services for sub-components, e.g. de Nora offer recoating of membranes to extend their lifetime (de Nora, 2023).

Towards the end of life of the overall product, the individual components have the potential to be dismantled, in parts reused, in other parts recycled, or end up as waste. For PEM FCH products, the PGM content makes recycling and recovery of materials economically attractive. However, due to the small market size, it is not yet widely practised, and scale is required to systematise end-of-life strategies. Further clarity is also required on the quality of recycled (secondary) raw materials and possibility to utilise other secondary material sources such as PGMs or titanium from recycled cars (Quilez ez al, 2017; IRENA, 2020).

*Drivers and barriers to CE*

In our stakeholder interviews it became apparent that with the current level of maturity of the sector, the clear priority of FCH OEMs lies in scaling and cost reduction. Therefore, substantial R&D spending is dedicated to reducing platinum loads for catalysts [A, B, D, E, G]. Costs of input materials are therefore a prominent and well-understood driver of the adoption of CE principles, though usually not labelled as such.

Our research has further identified drivers and barriers across all four categories described by de Jesus and Mendonca (2018). Figure 1 also shows four exemplary drivers and barriers and where in the value chain they are relevant. Further research through interviews with more stakeholders is required to further populate the visual and understand all the main underlying dynamics for the adoption of CE principles.

A technical barrier to the adoption of recycling and reuse strategies is the *lifetime uncertainty of FCH products limiting transparency on and expectations about end-of-life phase (1)* for most FCH products. As products are tested in laboratory conditions using accelerated stress testing protocols, current lifetime figures are estimates [A]. Potentially lifetime-influencing factors such as weather and temperature conditions or frequent powering on/off are not yet known to the full extent [A, D]. Without a clear view on component and product lifetimes, product design choices for component replacement are difficult to take and retirement decisions for devices inconclusive, not aiding reuse or recycling activities [A, D, C, G].

A cultural barrier to the adoption of further circularity strategies is the *short-term focus of businesses limiting foresight planning for future supply risks (2)*. Currently, most companies in the hydrogen sector are focused primarily on scaling their production and ensuring sufficient future demand for their products [D, E, H]. While

material shortages or sustainability ambitions feature in discussions and might even be a concern for market participants, R&D budgets are attributed to short-term problems in such a nascent industry [E, H]. This barrier also explains why reducing material intensity for PGMs is most advanced in private sector research as it has a short-term benefit for FCH products' costs (deployment CapEx) [C, D, E].
As the above-mentioned reports and studies have modelled, future supply risks for key FCH technology materials exist. Such *future raw material shortages increase input prices for key components (3)* and can act as an economic driver for the adoption of further circularity strategies, especially for recycling materials at the end-of-life of products in addition to the reduction of inputs [A, D, E]. Once OEMs have scaled their production processes, they will need to manage such risks and implement the technical processes already existent today.

Lastly, upcoming policies addressing the critical raw material issue are a regulatory driver. The *European Union is issuing reduction targets for the PGM content of PEM electrolysers (4)* in line with the Clean Hydrogen Joint Undertaking's recommendations and defined KPIs [A, F, H]. The target to reduce PGM intensity by a factor of ten by 2030 is ambitious, though it provides clarity and clear guidance for businesses. Furthermore, such targets are accompanied with budget and research support, making their achievement more likely.

## Conclusions

Our research is still ongoing as we are still engaging with stakeholders in the hydrogen sector to understand what drives or hinders the adoption of circular strategies. Hydrogen is going to play a central role in Europe's energy transition, so scaling the required technology for production and utilisation is key. As some of the required materials are considered critical, stakeholders in the EU are well-advised to consider and mitigate potential bottlenecks early to enhance its resilience and overall EU strategic autonomy. Furthermore, circular economy principles aid the EU's sustainability ambitions and can therefore link those two aims of its industrial policy. This research collects the different applicable CE strategies for FCH technologies and maps them to the value chain. For the best usability of this knowledge, it is crucial to aggregate the technical aspects to clear messages. Based on the technical feasibility, we then identified four drivers and barriers across four categories to generate a first understanding of what drives and hinders their adoption. This may help businesses and policymakers to address the challenges described and develop actionable measures.

From a theoretical perspective, this research contributes to the growing literature on drivers and barriers of the circular economy by furthering our understanding of what its determinants are. By describing the drivers and barriers for individual value chains, generalised patterns and observations can be distilled (see Kirchherr et al, 2018; Kennedy and Linnenluecke, 2022). To this end, further research into more sectors is needed. For businesses, an overview of the relevant circularity strategies can help with their business strategies as well as communicating their support needs to regulators. By creating transparency, expectation management becomes feasible. For policymakers, the drivers and barriers can inform clear policy actions that can be taken to promote the sustainable and resilient set-up of an important value chain in Europe. This research therefore supports the EU's Green Deal as well as its industrial policy ambition (EC 2019, 2021).

# Rebound effects of circular business models on the consumer level: a review

**Michał Bączyk, Vivian S.C. Tunn, Blanca Corona, Ernst Worrell**
Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, the Netherlands

**Keywords**: Circular economy, Sustainable consumption, Circular behaviour, Consumer behaviour.

**Abstract**: This paper addresses consumer behaviour in circular economy (CE), specifically by examining consumer-level rebound effects in response to circular business models (CBMs). Despite the centrality of consumer behaviour in CE, there is a limited understanding of how consumers engage with CBMs and to what extent the environmental benefits of circular strategies may be offset by their behaviour. To this end, we conducted a systematic literature review to assess the evidence from real-life case studies of CBMs. We identified consumer behaviours leading both to rebound effects, and to reduction of environmental costs of consumption. We also showed that consumer behaviour was influenced by contextual factors and by the characteristics of the CBMs. This suggests that CBMs may only enable sustainable consumption in specific contexts.

## Introduction

Circular business models (CBM) are practical and financially viable operationalizations of circular economy (CE) strategies of closing, slowing and narrowing of resource loops (Bocken et al., 2016; Geissdoerfer et al., 2017, 2020; Nußholz, 2017; Pigneur & Osterwalder, 2010).

However, deployment of CE strategies may lead to unintended systemic responses resulting in lower-than-expected economic, social, or environmental benefits, due to so-called rebound effects (Castro et al., 2022; Metic & Pigosso, 2022). CBMs bring new products and services to the markets or lead to the creation of new markets, thus we consider them to be innovations acting as potential rebound triggers. Further, we consider consumer behaviour to be a potential rebound driver because the magnitude of rebound depends on changes in consumption behaviour due to implementation of CBMs. In this context, we understand consumer behaviour as acts and processes of acquisition and/or use of goods and services (Poças Ribeiro et al., 2019). The realisation of the maximal environmental benefits of CBMs depends thus on consumer behaviour because it requires consumers to engage in a series of anticipated, circular behaviours (Camacho-Otero et al., 2020).

Despite the central role of consumer behaviour in CE, this topic has only recently been recognized (Castro et al., 2022; Ferasso et al., 2020; Metic & Pigosso, 2022; van Loon et al., 2021). There is a limited understanding of how consumers behave when engaging with CBMs, and real-life accounts are missing. To date, only one published study systematically reviewed rebound effects on the consumer level (Reimers et al., 2021). Nonetheless, it focused only on indirect rebound and did not address the context of CE. Furthermore, insights from energy efficiency economics cannot be directly translated into the context of CE (Castro et al., 2022; Hertwich, 2005). Thus, rebound effects on the consumer level triggered by CBMs, necessitate further investigation.

This study contributes to filling this research gap by answering: “How do consumers behave toward CBMs?”. This is accomplished with a systematic literature review focusing on empirical accounts of CBM implementations.

## Methodology

We conducted a systematic literature review (Smart et al., 2017), following the Tranfield et al. (2003) protocol.

### *Operationalization*
Against the theoretical background, we determined two outcomes of consumer behaviour toward CBMs. First, *conservation* being consumption behaviour in line with the anticipated benefits of CBMs, leading to lower environmental burdens compared to satisfying a need with an equivalent linear product or service. Second, *rebound* being consumption behaviour leading to offsetting of the potential environmental gains. To distinguish rebound mechanisms, we follow the typology proposed by Metic and Pigosso (2022), Table 1.

| Level | Direct effects | Indirect effects |
|---|---|---|
| Micro | Price<br>Income<br>Time<br>Motivational | Re-spending<br>Substitution<br>Motivational<br>Consumption accumulation |
| Meso | Sufficiency | N/A |

**Table 1. Circular economy rebound types and mechanisms on the consumer level.**

Because of divergent CBMs nomenclature (Lüdeke-Freund et al., 2019), we included all business models (BMs) identified in the prominent papers on CBMs (Bocken et al., 2016; Lüdeke-Freund et al., 2019; Nußholz, 2017), to capture the breadth of the most commonly used terms, see Table 2.

### *Inclusion criteria*
Given the focus on consumers, we examined empirical papers on business to consumer (B2C) and consumer to consumer (C2C) BMs CBMs where consumer behaviour is addressed explicitly. In the case of C2C BMs, we focused only on for-profit settings where consumer interactions are facilitated by a firm. We did not apply any selection criteria regarding the industry product types, or temporal scope.

### *Search terms*
We collected data from articles published in peer reviewed journals, written in English, accessible in January 2023 in multidisciplinary academic databases suitable as primary search engines (Gusenbauer & Haddaway, 2020): Web of Science Core Collections and Scopus.

We created search strings by linking key words related to CBMs from Table 2 with *"consumer behaviour OR user behaviour"* using Boolean AND operator.

### *Coding*
In the first coding cycle, we extracted descriptive information about each case and key findings about consumer behaviour. In the second coding cycle, we associated consumer behaviour to rebound and conservation mechanisms, and in the third coding cycle we synthesized contextual and BM related factors influencing consumption.

## Results
We have identified 1053 non-duplicate articles and included 10 in the sample after having applied inclusion criteria to abstracts and full text. Table 3 presents the overview of the selected case studies.

In the sample, we identified four conservation mechanisms related to consumption behaviour and two rebound mechanisms.

### *Conservation mechanisms*
CBMs facilitated *product lifespan extension* through preservation of product functionality by repair and maintenance behaviour. Owners of modular and semi-modular phones were more likely to repair their smartphone, with repair rates of 87% and 85% (Amend et al., 2022), compared to average 25% repair rate of regular smartphones (Jaeger-Erben et al., 2021).

| Strategy | CBMs |
|---|---|
| Slowing | Functional sales, Gap-exploiter, Hiring, Leasing, Lifetime products, Long-lasting products, Next-life sales, Pay-per-use, Product as a service, Product service system (PSS), Product sharing, Product value extension, Re-marketing, Refurbished products, Remanufactured products, Renting, Repairable products, Second hand products, Sharing platform, Upgradeable products, Used products |
| Closing | Circular products, cradle-to-cradle, green products, Products made of recycled and/or recyclable materials |
| Narrowing | Eco-efficient products |

**Table 2. Circularity strategies and CBMs.**

| Description | CBM | Consumption category | Product | Location | Sample | | Key findings |
|---|---|---|---|---|---|---|---|
| | | | | | Survey | Interview | |
| Car sharing (Retamal et al., 2022) | PSS | Mobility | Car | Japan | 998 | 49 | Car sharing used both to substitute and complement private vehicles |
| Bicycle subscription (Niessen et al., 2023) | PSS | Mobility | Bicycle | Germany, The Netherlands, Belgium, UK | 122 | 54 | Bike subscribers cycled more frequently and over larger distances than before |
| Pay-per-use washing machine (Bocken et al., 2018) | PSS | White goods | Washing machine | The Netherlands | 77 | 77 | Domestic pay-per-wash reduced average washing temperature and frequency |
| Clothing library (Johnson & Plepys, 2021) | PSS | Consumer goods | Clothing | Sweden | 57 | - | Clothing rental substituted and complemented purchases of new dresses |
| Shared laundry #1 (Moon et al., 2019) | PSS | White goods | Washing machine | Thailand | 192 | 69 | Laundromat-only users had the lowest number of annual washing cycles, those using both private washing and laundromats had the highest |
| Shared laundry #2 (Moon et al., 2020) | PSS | White goods | Washing machine | Thailand, Japan | 170 + 185 | - | Tokyo: shared machines used generally in addition to domestic laundry; Bangkok: shared machines used generally as a substitute of domestic laundry |
| Shopping on the second- hand platform (Parguel et al., 2017) | Second-hand platform | Consumer goods | Durables and semi-durables | France | 541 | - | Second hand platforms encouraged indulgent consumption |
| Modular smartphones (Amend et al., 2022) | Repairable products | Electronics | Smartphone | Germany | 1720 | - | Smartphone modularity enhanced repair behaviour when paired with repair services |
| Smartphone reuse (Makov & Vivanco, 2018) | Second-hand products | Electronics | Smartphone | USA | 341 | - | Second hand phones substituted nearly half of the demand for new devices |
| Peer-to-peer boat sharing (Warmington-Lundström & Laurenti, 2020) | Product sharing | Leisure | Boat | Finland | 104 + 29 | - | Lessees: boat renting substituted nearly half of new boat purchases, savings re-spend in other consumption categories; lessors: additional income spent on boat maintenance or personal use, and in other consumption categories. |

**Table 3. Overview of the selected case studies.**

Modularity had a positive effect on self-repair and use of repair service. Similarly, in the study of boat sharing, 55% of lessors prolonged life of their boats by investing additional income from renting into maintenance (Warmington-Lundström & Laurenti, 2020).

Circular offerings played a role in *formation of pro-environmental habits*. Lower environmental burden was achieved in laundry and mobility habits. Users of pay-per-use domestic washing machines reduced laundry temperature and frequency over timespan of two to five months (Bocken et al., 2018). Similarly, shared laundry users run fewer wash cycles per year compared to those who washed only at home and those who supplemented domestic laundry with shared laundry, even when accounting for differences in maximum load (Moon et al., 2019, 2020).Regarding mobility habits, bike subscriptions enabled a modal shift away from high-emission means of transport (Niessen et al., 2023). The subscribers intensified cycling: they biked more frequently and travelled longer distances. Even after the subscription expiry nearly two thirds of users, who did not cycle before, continued to cycle.

Availability of car-sharing service (CSS) allowed users to meet their mobility demands with a lower material footprint trough *substitution of ownership with access* to a shared vehicle (Retamal et al., 2022).

Lastly, in some cases, circular offerings were chosen instead of linear ones, leading to *substitution of demand for new products.* Dresses rented from a clothing library substituted 70% of demand for new apparel (Johnson & Plepys, 2021), second-hand phones replaced 58% of new phones that would have been bought otherwise (Makov & Vivanco, 2018), and peer-to-peer boat sharing replaced 43% of the demand for new boats (Warmington-Lundström & Laurenti, 2020).

### Rebound mechanisms

In half of the cases, CBMs supplemented consumption of conventional products and services, leading to *consumption accumulation.* Shared cars were used in addition to already owned vehicles (Retamal et al., 2022), clothing rental was accompanied with purchases of new apparel (Johnson & Plepys, 2021), shared laundry facilities were used on top of domestic laundry and encouraged use of tumble drying instead of natural drying (Moon et al., 2019, 2020). Lastly, users of a second-hand platform made impulsive purchases and acquired excessive numbers of items (Parguel et al., 2017).

*Re-spending* was the focal point of two studies: smartphone reuse (Makov & Vivanco, 2018), and boat sharing (Warmington-Lundström & Laurenti, 2020).Environmental benefits of engagement with CBMs were offset by re-spending when money saved thanks to engaging in circular consumption was directed to purchases of other goods and services. In the case of used phones, re-spending was the main contributor of rebound effect because the savings were spent on consumption with high environmental costs such as food, non-durable goods and transportation. In the case of boat sharing, more than half of lessees of boats redirected their extra income to travelling.

### Consumption and consumer context

Consumption accumulation tended happen when CBMs were enabling conspicuous consumption, as a way to signal *social status* (i.e. driving a sports car or wearing a dress to stand out). Contrarily, conservation was observed when consumers engaged with CBMs a as primary mode of meeting their needs (i.e. doing laundry exclusively at a laundromat).

*Socio-cultural context* influenced consumption accumulation. For example, in Japan owning a washing machine is considered an essential need. Shared laundry thus was generally used in addition to private washing, spurring additional consumption. However, in Thailand, the high share of exclusive shared laundry users was related to the *spatial-infrastructural context*, namely lack of space for a washing machine at home. Similarly, in Japan, the successful substitution of private car ownership with CSS was feasible because an excellent public transportation system made living car-free possible, and high parking costs made it financially attractive. Likewise, in Sweden, low carbon footprint of clothing rental was achievable because most consumers used low-emission public transport to get to the store.

*Change of life circumstances* facilitated more sustainable consumption trough engagement with CBMs. Both bike subscribers and users of shared laundry formed new habits after moving to a new city or country.

Regarding *consumer context*, we saw that consumer characteristics influenced the outcomes of engagement with CBMs, for that behaviour depended on consumer segment. For example, “eco-friendly” clients of the clothing library constituted only a fifth of the customer base. Only a third of shared laundry users in Bangkok did laundry exclusively at shared laundry facility, which had the lowest environmental impact, compared to other consumer segments. This suggests that CBMs enable sustainable consumption among only a fraction of consumers. *User heterogeneity* had thus a significant effect on the magnitude of rebound effects. For instance, 45% of boat sharing users causing rebound were responsible for 47% of rebound effect. Thus, a minority user type wiped out the environmental savings made by other users.

Surprisingly, we saw that pro-environmental *values* played little role in engagement with CBMs. This could be explained by norm deactivation by situational factors. In the of context sustainable consumption, people who generally endorse pro-environmental values might act against them when they must balance and manage multiple, conflicting goals (Steg, 2015).

### *Business model and product characteristics*

The three cases presenting only conservation mechanisms had a common denominator: the CBM was built around sufficiency. The pricing structure of the pay-per-wash encouraged lower laundry temperatures, modular phones were designed to facilitate repair, and the bike subscription enabled a modal shift toward a “zero” emission vehicle in the use phase. Nonetheless, the convenience offered by CBMs contributed to consumption accumulation: the use of additional tumble-drying service substituted natural drying, and large shared washing machines were used to wash items too large to fit a private washing machine. Interestingly, the second-hand platform provided a favourable context for self-licensing behaviour and reduced cognitive dissonance, even among “pro-environmental” consumers.

## Discussion and Conclusion

The results show that consumer behaviour toward CBMs indeed leads to rebound effects through consumption accumulation and re-spending but also to conservation through creation of pro-environmental habits, the substitution of ownership with access, and the substitution of demand for primary products.

Nonetheless, CE rebound through consumption accumulation seems to be one of the most prominent rebound mechanisms, with CBMs being an additional engine of growth (Laurenti et al., 2016). This challenges the preposition that sustainable consumption can be achieved through circularity. Rebounds were only absent in sufficiency-based BMs. However, such BMs were viable in specific socio-cultural, infrastructural consumption contexts. Our findings are in line with recent publications on factors influencing circular consumption systems (Gomes et al., 2022).

We identify three main caveats of the reviewed body of literature. First, only one study performed direct measurement of behaviour. The other studies relied on surveys, which might not be fully representative of actual behaviour because humans do not remember everything they do, make estimation errors, or provide socially desirable answers. Second, survey-based approach allowed describing consumer behaviour; however, it inhibited the authors from putting forward in-depth explanations of the observed behaviour. Third, while some studies provided statistics about user behaviour per consumer segment, many were limited to qualitative accounts. As a result, the magnitude of rebound could not be estimated, given the high user heterogeneity. Thus, future studies should combine rebound quantification with psychological and sociological theory-driven approaches to produce in-depth insights into consumer-related rebound effects (Bögel & Upham, 2018; Evans, 2018; Warde, 2015).

This review study has several limitations. First, the number of identified cases was relatively low, probably due to the low number of empirical peer-reviewed studies on the topic.

Second, the identified cases spanned across a wide range of CBMs, product categories and geographical locations. This heterogeneity combined with a small sample limits the external validity of our synthesis. To overcome these limitations, further cases should be identified through snowballing and a search in grey literature.

To conclude, this study contributes to the burgeoning field of research on unintended consequences of CE by mapping the knowledge on consumer-related rebound effects of CBMs. Future work should focus on developing case studies across different consumption categories and socio-cultural settings.

# Barriers and Enablers for the Implementation of Design for Sustainability in Flemish Design Agencies

**P. Beerten[a,b], F. Ostuzzi[c], L. Brosens[c]**
a) Université Libre De Bruxelles (ULB), Brussels, Belgium
b) Sustenuto, Brussels, Belgium
c) Department of Industrial Systems Engineering and Product Design, Design.Nexus, Ghent University, Kortrijk, Belgium

**Keywords**: Design for Sustainability; Circular Economy; Sustainable Product Design; Design Practitioners; Barriers and Enablers.

**Abstract**: To address today's sustainability challenges a shift is needed in the way products are designed. The behavior of design practitioners plays an important role in this as 80% of a product's environmental impact is determined during the design phase. The Fogg Behavior Model (FBM) shows that three elements (Motivation, Ability and Trigger) are needed for behavioral change. When applying this to Design for Sustainability (D4S), the consideration and harmonization of ecological, economic and social aspects in the design process, which includes Product Lifetime Extension, multiple barriers and enablers that influence FBM, could be identified. This study aims at mapping these in the context of Flemish design agencies. The goal is thus to identify the barriers and enablers designers in Flemish design agencies face when applying D4S and how these affect the behavior of these practitioners. For this, multiple (n=9) semi-structured interviews have been performed and analyzed using an adapted approach, this to challenge the preconceived hypotheses. Results show that multiple aspects influence the designer's behavior. These aspects can be subdivided into four main external categories, Design agency, Client requests and constraints, Government and Non-customized tools. It is unclear what the personal motivation of design practitioners is to apply D4S, but limited knowledge on this subject hinders them in doing so. The researchers hope to contribute to the D4S research field and make its application standard practice.

## Introduction

In order to tackle the current sustainability challenges a radical change is needed in the way we design products (Ceschin & Gaziulusoy, 2020). In fact, up to 80% of a product's environmental impact is already determined during the design phase (European Commission, 2022). McAloone (2009) claims that this lock-in effect already occurs at the conceptual phase of the development process. So, the behavior of design practitioners when designing products plays a crucial role in the sustainability transition.

Despite the urge to tackle these sustainability challenges, and the role that product design can play in the transition, industry has not yet adopted sustainable design as standard practice (Faludi et al., 2020). To understand what factors are restricting the uptake of sustainability in design processes, this research will examine the barriers and enablers of sustainable product design in Flemish Design agencies.

The research scope is focused on product design agencies. Design agencies, in general, carry out projects for a variety of products, sectors and industries. So, unlike industrial companies who normally are specialized in one, or a range of, products, they can detect barriers that occur for different types of products. Previous research focused on the implementation of sustainability, Design for Sustainability (D4S) or specifically circularity in Dutch, Turkish and British design agencies or architecture firms. They discussed the importance of sustainability in design and acknowledged the role of product designers in the sustainability transition (Dokter et al., 2021; Küçüksayraç et al., 2015; Storaker et al., n.d.). None of the researchers looked at the Flemish context or how the barriers and enablers experienced when integrating sustainability holistically, by applying D4S, in product design influence the behavior of design practitioners.

## Design for Sustainability (D4S)

Design for Sustainability can be defined as the consideration and harmonization of ecological, economic and social aspects in the design process (Curtis & Walker, 2001; Mayyas et al., 2012; Spangenberg et al., 2010). To facilitate this, Life Cycle Thinking is applied and considers each life phase stage of the designed solution (Clark et al., 2009; Faludi et al., 2020). Other sustainable design methodologies, approaches, or tools focus on one or two aspects simultaneously e.g. Lifetime Extension focuses on technical aspects and consumer behavior to increase the life-span of a product for lowering the ecological impact (Cooper, 2010; den Hollander et al., 2017). Others like Life Cycle Assessments (LCAs) look at environmental (Finnveden et al., 2009) or social (Russo Garrido et al., 2018) aspects, Ecodesign focuses on the environmental and economical aspect (Karlsson & Luttropp, 2006), but none focus on all aspects simultaneously to fully integrate Sustainability. D4S thus goes beyond philosophies, approaches and tools such as Ecodesign, LCAs, and Product Lifetime Extension (Spangenberg et al., 2010), and can be seen as an overarching term incorporating these various facets.

D4S can be subdivided into five innovation levels (material/component, product, product-service system, spatio-social and socio-technical system), as introduced by Ceschin & Gaziulusoy (2020) (Figure 1), evolving from an insular/technocentric towards a systemic/human-centered focus. When D4S is applied in its totality, the designer needs to simultaneously consider the detailed material level and the broader socio-technical aspects, which in itself can be very complex. This without considering potential external factors that may hinder or enable the implementation of D4S.

Additionally, behavioral change is needed for a Sustainability transition (Schäpke & Rauschmayer, 2014). When translating this to the product designer's context, the design practitioner should adopt altered values, attitudes, habits and behaviors (Frisk & Larson, 2011). Fogg Behavioral Model can help to demonstrate how this can be achieved for D4S.

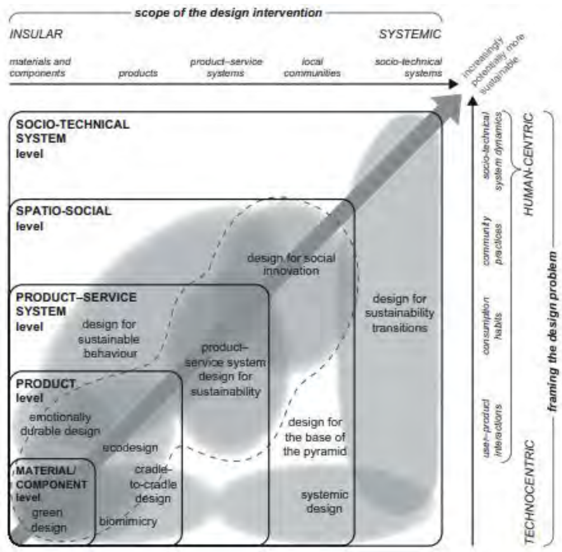

**Figure 1. Innovation level framework with D4S approaches. (Ceschin & Gaziulusoy, 2020)**

## Fogg Behavioral Model

The Fogg Behavioral Model (FBM) shows that behavioral change occurs when its' three main elements (motivation, ability, and triggers) converge at the same time (Fogg, 2009). FBM has been applied to the sustainability transition in various studies, including studies on promoting energy conservation (Geelen et al., 2012), food waste reduction (Akmal & Niwanputri, 2021), and sustainable transportation (Moretti et al., 2021). These studies have shown that interventions designed based on the FBM have resulted in behavior change towards more sustainable practices.
Within the scope of this research, Figure 2 shows the identified barriers preventing the application of D4S. Limited references have been found on the level of knowledge (practical and theoretical) of designers with regards to D4S (or, more generally, sustainability), and life-cycle thinking. A limited knowledge level of these subjects could influence their abilities to design products well towards these principles (Seager, 2008).

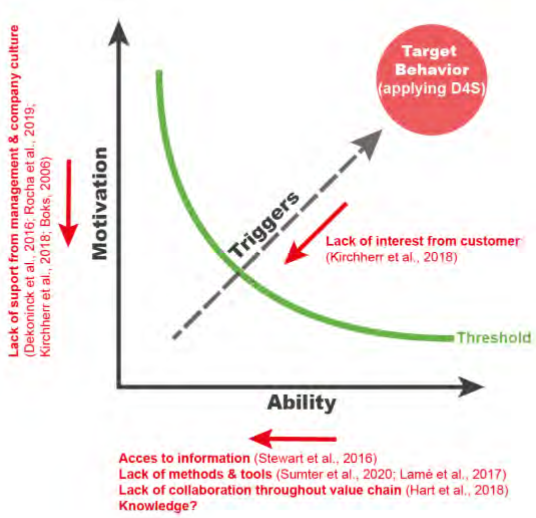

**Figure 2. Identified barriers for D4S applied to the FBM (Dekoninck et al., 2016; Hart et al., 2019; Kirchherr et al., 2018; Rocha et al., 2019; Stewart et al., 2016; Sumter et al., 2020)**

By translating these barriers into the FBM, the following hypotheses are established:

1. Design practitioners have a personal motivation but are not motivated by the company they work for to apply D4S.
2. Insufficient knowledge, inadequate supporting tools (as they are too complex, time consuming and are insufficiently integrated into their design methodology) and lack of time and money are limiting the designer's ability to work on D4S.
3. Designers are more frequently triggered to work on D4S by clients.

## Methodology

*Research Approach*

To verify these hypotheses, this study used semi-quantitative interviews as the research methodology.

Through open-ended questions asked in a semi-structured interview, a richness of data can be gathered on the participant's perceptions, experiences and attitudes, aiding in understanding why people act a particular way (Harvey-Jordan et al., 2001). These questions are drafted in a three step process. First, identifying the topics to be investigated and its boundaries. Second, structuring the categories of the topic, and Third, identify the question stems (McIntosh & Morse, 2015). The outcome of this process, the structure of the questions used in this study, can be found in Figure 3.

*Participants*

When selecting participants for this research, the aim was to include a variety of profiles, this in terms of experience level in design and sustainability, job position, and size of the company. All participants were required to have a product design related educational background.

Table 1 shows an overview of the participants of this study and their employers. This information has been obtained during the interviews supplemented with information from the company's website and their LinkedIn page.

| Company ID | Participant ID | Company size | Offered services | Years of experience | Role in Organization |
|---|---|---|---|---|---|
| 1 | 1 | Small | Product design, Service design, Engineering | 20-30 | Manager, Product designer |
| 2 | 2 | Micro | Product design, Engineering | +30 | Owner, Manager, Product designer |
| 3 | 3 | Medium | Product design, Service design, Business (strategy) design, Engineering | 10-20 | Manager, Strategic designer, former product designer |
| 4 | 4 | Small | Product design, Business design, Engineering | 5-10 | Product designer |
| 5 | 5 | Medium | Product design, Service design, Business (strategy) design, Engineering | 20-30 | Owner, Manager, Product designer (<25%) |
| 6 | 6 | Medium | Product design, Engineering | 0-5 | Product designer |
| | 7 | | | 20-30 | Manager, Product designer |
| 7 | 8 | Large | Product design, Service design, Business (strategy) design, Engineering | 0-5 | Product designer |
| | 9 | | | 20-30 | Manager, Strategic designer, former product designer |

**Table 1. Information on Participants. Company size (employees): micro < 10, small < 30, medium < 50, large > 50**

*Data Collection*

As Table 1 shows, a total of nine individual interviews were conducted at seven design agencies. All design agencies are based in Flanders, some have activities abroad. The interviews were conducted between November 2022 and February 2023, and lasted between 40 and 65 minutes. The majority of interviews were conducted face-to-face (n= 8), only one was performed online (n=1). All interviews were in Dutch. If multiple participants from the same design agency were interviewed, this was done separately and the participants did not have the opportunity to discuss the questions. With permission of the participants, the audio was digitally recorded and afterwards analyzed.

This data can be made available on request. Due to the confidentiality of the topics discussed, all participants, design firms, and projects mentioned, have been anonymized.

### *Data Analysis*

For the data analysis a five step approach was applied adapted from Schmidt (2004), 1. determining analytical categories, 2. development of a guide for coding, 3. coding of the interviews and reevaluating analytical categories, 4. quantifying of results and step 5. interpretation and translation of results.

Figure 3 shows the analytical categories that were identified and linked to the FBM. These categories were used to base the coding guide on.

During the coding of these predefined codes, the following new interesting categories were identified and included in the analysis.

- Structure of the company to work around sustainability (Ability)
- How are decisions made (behavior of participant)

## Results and Discussion

The results have been subdivided in six subsections of which five can be linked to the hypotheses (H) and one gives an overview of all the findings.

### *Personal motivation (H1)*

Participants defined sustainability as "using the natural resources at our disposal as efficiently as possible", "don't mortgage resources now for future generations" and "build something that is future proof". Moreover, four participants indicated to have a personal motivation to work on sustainability of which two indicated that being engaged in sustainability is a fundamental part of their lives. The other two are engaged if it falls within their "area of interest".
As for the relationship between design and sustainability, Figure 4 shows the participant's estimation to what percentage of a product's environmental impact is already determined during the design process.

A conclusion from these results could be that some definitions of participants seem to be very limited (being very vague or only focused on one aspect e.g. eco-efficiency). Furthermore, only a few indicated to be truly personally motivated on sustainability and the majority underestimate the impact they can have. This all can cause the motivation to work on D4S to be low.

| Question category | Question | | Analytical category | FBM aspect |
|---|---|---|---|---|
| Personal background | What is your age? | | | |
| | What have you studied? | | | |
| | Could you describe your previous work experience? | | | |
| | What is your current role in the organisation? | | | |
| | What is the current size of the company? | | | |
| Theoretical knowledge level | How would you define sustainability? | ➡ | Definition of sustainability | Motivation, Ability |
| | How would you define product design? | | | |
| | What is, in your opinion, the relationship between design and sustainability? To what extent, in percentages, does product design influence sustainability? | ➡ | Relationship design and sustainability | Motivation |
| | How would you rate your knowledge level, on a scale from 1 to 10, your knowledge of sustainability, design and design for sustainability and why? | | | |
| Practical knowledge level | Can you describe some projects where you applied D4S? | | | |
| | You listed a series of concepts, strategies and tools related to D4S for example, (read ones they mentioned during previous question).<br>- Could you go more into detail/give practical examples of when did you use them?<br>- At which stage of the design process has this been used, mainly?<br>- Who were the actors involved?<br>- Did you use specific tools, techniques or methodologies?<br>- What were barriers / enablers?<br>- How do you evaluate the outcome? | ➡<br>➡<br>➡ | Applied D4S philosophies, methodologies, approaches or tools<br>Mentioned barriers<br>Mentioned enablers | Ability<br>Motivation, Trigger, Ability<br>Motivation, Trigger, Ability |
| | Could you define:<br>- Ecodesign<br>- Design for circular economy<br>- Emotionally durable design<br>- Design for sustainable behaviour<br>- Cradle to Cradle<br>- Biomimicry<br>- Product service system<br>- Design for the base of the pyramid<br>- Design for social innovation<br>- Systemic design<br>- LCA's<br>- Checklists<br><br>- Have you ever used it in practice?<br>- (if yes, go back to previous question)<br>- (if no) why not? | ➡ | Known D4S philosophies, methodologies, approaches or tools | Ability |
| Specified questions | To what extent are you aware of recent legislations such as the EU circular economy action plan and the EU ecodesign directive? How do you experience these initiatives? | ➡ | Awareness of legislation | Trigger |
| | Have you had projects where sustainability criteria were imposed from the client? | ➡ | Client requests | Trigger |
| | Do you feel you have enough resources to work on design for sustainability? | | | |
| | Have you ever felt you needed extra guidance on sustainability? | | | |
| | What are the strategies internal to your company to work on D4S? | ➡ | Company strategy | Trigger, Ability |
| | Are there any other barriers or enablers, not yet mentioned, preventing you from working on Design for Sustainability? | | | |
| | | | Personal motivation | Motivation |

**Figure 3. Interview Questions and Analytical Categories.**

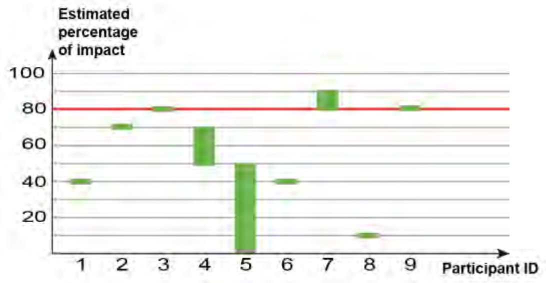

**Table 4. Participants estimated impact of the design process on product's environmental footprint.**

## *Company motivation (H1)*

On company strategy, participant responses show that five (n=5/7) investigated companies are currently looking to, or have already, strategically incorporated sustainability into their service offerings (e.g. "we actually have three pillars prioritized, ..., sustainable environment is actually one of them", "commercially we say that is a track we should go to").

One participant's company has a core team of two persons working on sustainability. At another company they use a chat group to enable this specialization, which according to the participant "turns out to be incredibly widely supported". None of the other participants mentioned any form of structural approach. Concluding from this, design agencies are more frequently incorporating sustainability in the company structure which could trigger or motivate the design practitioner to work on D4S. However, it is still unclear exactly how this will be implemented practically.

## *Triggers (H3)*

Eight out of nine participants have been given sustainability criteria by the client. The other participant mentioned receiving such a request "rarely if ever". Some examples of requirements the participants mentioned are: "that goes from very open opportunities and challenges to this trigger we don't want it out of plastic anymore", "my product should be ecological", "we want ecological packaging, cardboard, just do cardboard" and "we actually want reusable packaging".

Four participants indicated to have absolutely no knowledge on upcoming sustainability legislation (e.g. EU Ecodesign Directive), two indicated to be somewhat aware of these initiatives but don't know what they mean concretely, and three indicated to be aware of this of which one claims to have read it.

It could be concluded that designers are more often triggered by clients to work around D4S but are not sufficiently aware of upcoming legislation. It is also not yet certain whether the client's requests give designers the ability to work on D4S since they seem fairly vague or steering.

## Knowledge level (H2)

On a scale of 1 to 10, participants scored themselves on average a 6.6 (min. 3.5, max. 8) for knowledge of D4S. This while participants scored themselves an average knowledge level of product design of 8.4 (min. 7, max. 9).

Figure 5 shows an overview of the D4S philosophies, approaches and tools the participants indicated during the interview that they knew or applied. Trigger cards, business model canvas for sustainability and life cycle thinking have not been included in this table as it only was mentioned once by a participant that applies it.

(Df) Design for — K Participant indicated to Know
(u.o.) Use of — A Participant indicated to Apply

**Figure 4. Known and Applies D4S methodologies, approaches and tools.**

Some examples of definitions given for Ecodesign are “ecologically responsible design”, “working with recycled materials or with natural materials” and “Ecodesign is a broader concept than Cradle to Cradle”. Systemic design the participants defined as “having insights in the needs of all stakeholders, …, a way of … visualizing a complex situation” and “our waste for who can that be a source”.

One participant indicated to reduce the amount of material because “that costs the customer the most” another one indicated to do this after an environmental impact analysis, the other two did not indicate why they applied it.

For the use of biomaterials, the designer either used wood or cardboard.

Participants that indicated to focus on Lifetime Extension of the product did so by increasing the quality of the product (“that you make the product sturdier”, “weather and wind resistant which makes that super long lasting”, “so it is strong, that no components break off”). It is unclear if this comes from a sustainability focus or customer demand. Two indicated to apply emotional durable design by “not going to design products that look flashy, …, but are outdated within two years”.

Ecolizer is a simplified LCA analysis tool which is no longer available (OVAM, 2023).
As for design for social innovation, the participant indicated to do projects “specifically focused on seniors, … or people being in certain poverty classes”.

Looking at the results, it could be concluded that the participants had limited knowledge of D4S. Their knowledge of design is still higher than their knowledge of D4S. Additionally, some definitions they gave on D4S aspects were fairly vague and applied aspects seem to stem primarily from economic rather than sustainability motivations, are limited to the product and product service system innovation levels and do not appear to have been thoroughly applied (e.g. use of biomaterial is limited to wood and cardboard).

*Mentioned Barriers & Enablers (H1, H2, H3)*
Concluding from Figure 6, the client (see barriers in red) and insufficient tools seem to be the biggest causes of barriers. Tools do not seem to be too complex but rather not customized to the design methodology (being too generic or specified). Company culture seems to be both an enabler (by wanting to focus on sustainability) and a barrier (by not providing enough structure/support). Government seems the biggest enabler for D4S. For example, legislation was mentioned as an important enabler. This is confirmed by Horn et al. (2023), stating that legislation is important for enabling Ecodesign if it is not ‘hard, unpredictable, confusing or contradictory’ and we would like to add, as previously discussed, unknown.

Contrary to what is stated above, personal motivation has been mentioned as an enabler. Yet, their impact might be limited and the definition of sustainability is quite narrow, so we cannot conclude whether the motivation of practitioners is great enough to engage in D4S.

Related to decision making in the design process, four participants mentioned that they either use their gut feeling (e.g. “when it comes to sustainability and ecology, we use more our gut feeling”, “we are quite on autopilot, because we already have so much experience”) or follow the client’s lead (e.g. “that was the idea of *client name*”).

Note that if this gut feeling is based on insufficient knowledge, as previously discussed, it may be counterproductive in making the product more sustainable.

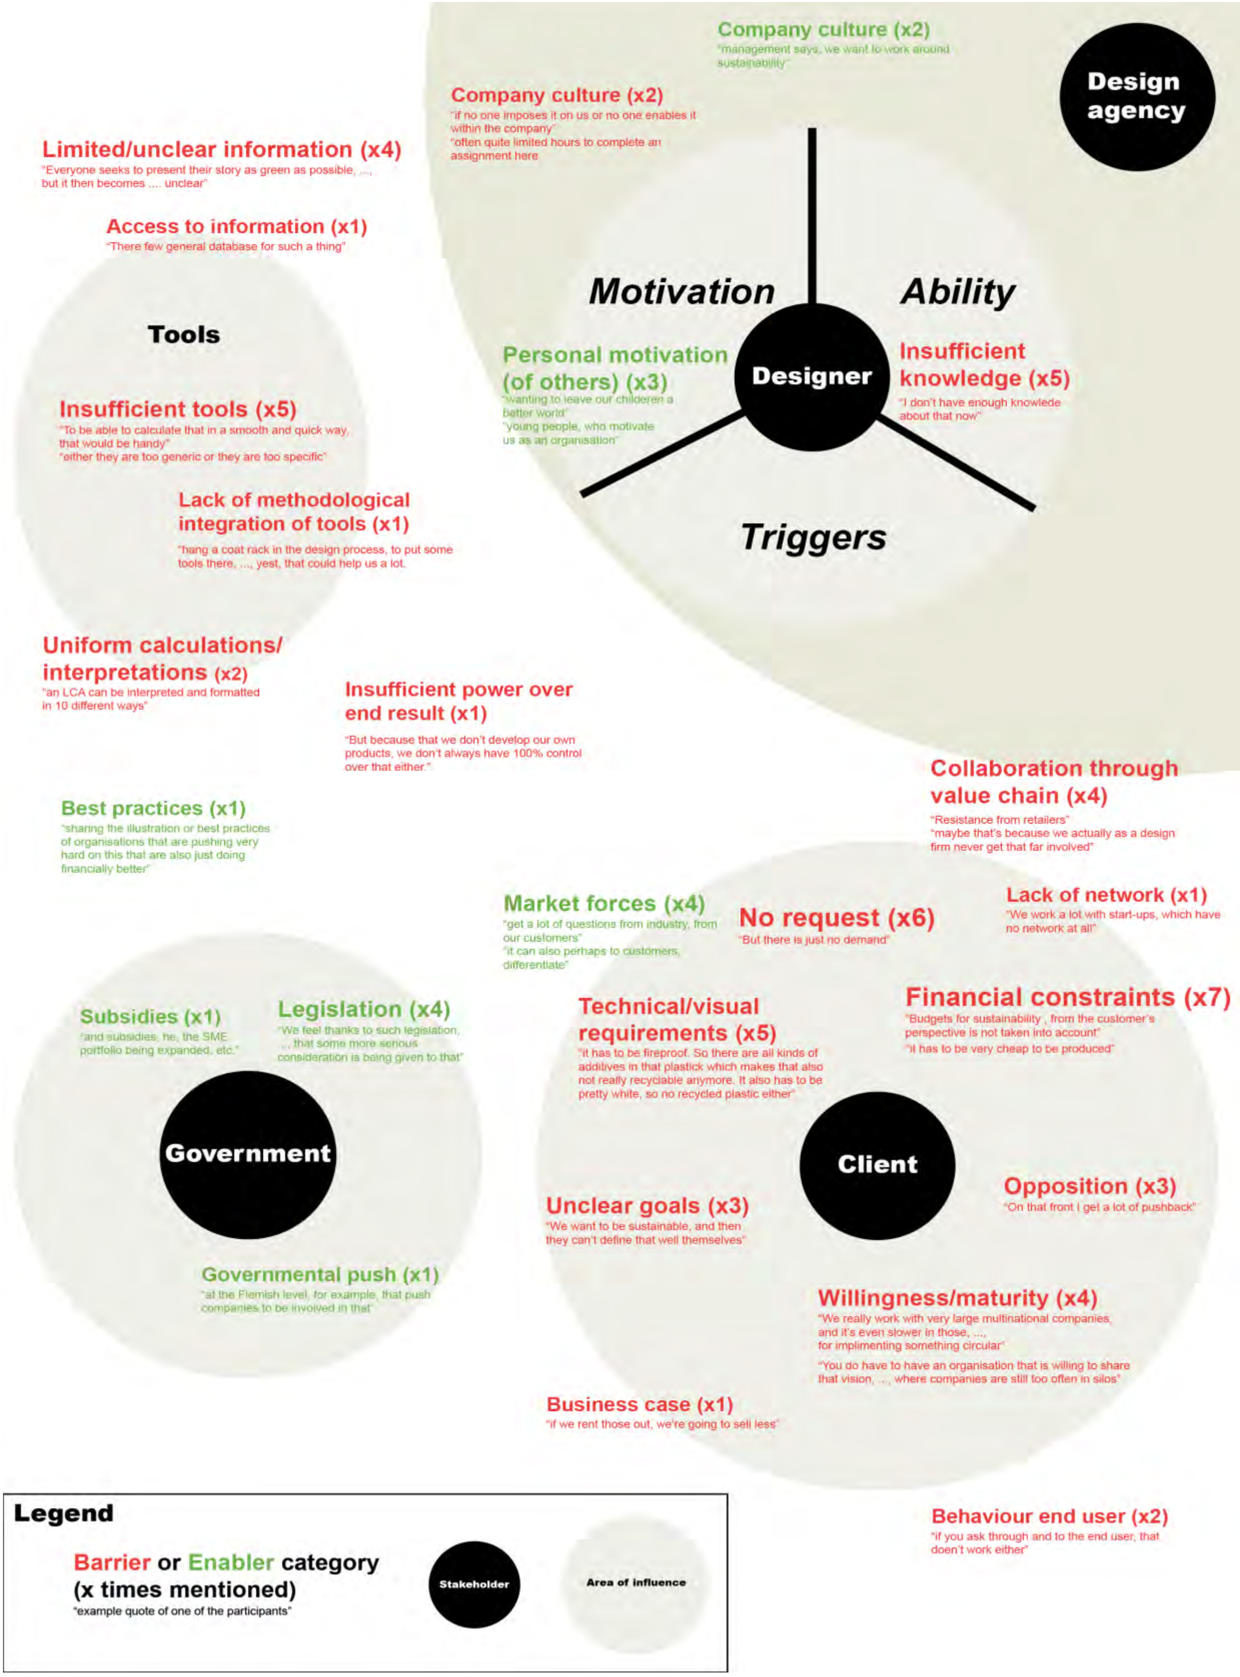

**Figure 6. Mentioned Barriers & Enablers by participants.**

*Motivation, Triggers & Ability (summary)*
Figure 7 shows how the identified barriers (red) and enablers (green) can relate to the FBM aspects of the design practitioner. All aspects of this figure have been previously discussed.

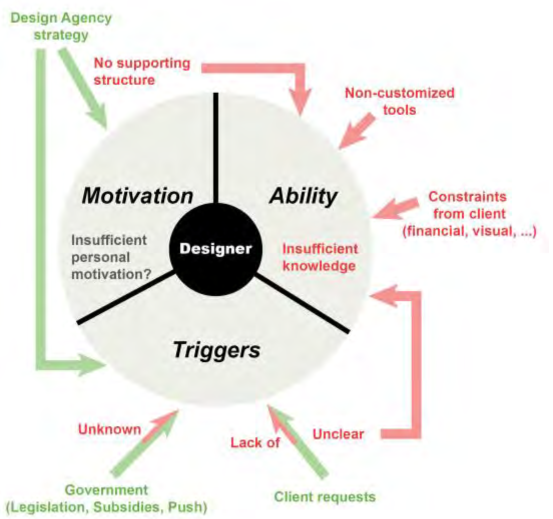

**Figure 7. Overview of Barriers and Enablers.**

## Conclusion
The behavior of design practitioners when designing products plays an important role in the sustainability transition. Therefore, this research focused on the barriers and enablers encountered when applying D4S and their link to the FBM. Nine semi structured interviews at seven Flemish design agencies were performed. From these interviews we conclude that:

1. It is uncertain whether designers have sufficient personal motivation to work on D4S but are more frequently encouraged by the design agency to do so.
2. Insufficient knowledge, non-customized tools, constraints and unclear sustainability requirements from the client are limiting the designer's ability to work on D4S.
3. Designers are more frequently triggered by the design agency, government and possibly clients to apply D4S aspects but have insufficient awareness of upcoming legislation.

Further results show that D4S aspects, such as Lifetime Extension, are not necessarily applied from a sustainability point of view but rather from economic or quality considerations.

By identifying these barriers and enablers, we hope to contribute to the standard implementation of D4S in design processes. Future research could focus on how tools can be best integrated into design methodologies to promote this standard integration.

## Acknowledgments
Special thanks to the participants of the interviews and the two anonymous reviewers of the abstract for their input.

# Digital battery passport information content for end of (first) battery life management support

**Katharina Berger[(a)], Rupert J. Baumgartner[(a)], Martin Weinzerl[(b)], Johann Bachler[(b)], Josef-Peter Schöggl[(a)]**
a) University of Graz, Graz, Austria
b) AVL List GmbH, Graz, Austria

**Keywords**: Sustainable product management; Circular economy; Digital product passport; Qualitative content analysis.

**Abstract**: The transition towards more circular electric vehicle battery (EVB) value chains can be enabled by pursuing value-retaining strategies (e.g., repurposing, recycling). However, to identify and support an appropriate value-retaining strategy, value chain actors located at the end of (first) life require product life cycle data for decision support. In this context, the digital battery passport (DBP) may function as a decision support tool as it has the potential to provide value chain actors with such data. This work explores data needs and requirements of EVB value chain actors affiliated with the end of life (EoL) and battery second use (B2U) in the context of sustainable end of (first) battery life management. Hence, empirical data was gathered by conducting 12 semi-structured expert interviews. The qualitative material was then subjected to a qualitative content analysis. The derived results highlight the relevance of detailed knowledge of battery chemistry compositions and dismantling instructions for supporting EoL processes (i.e., recycling). For B2U support, on the other hand, information about the battery health status, followed by dismantling instructions was perceived as relevant. Regarding current challenges for data inaccessibility, participants stressed the presence of data gatekeepers, lack of data sharing incentives, and lack of standardization (e.g., data formats). The theoretical contribution is given, as this work enhances the stream of literature on digitalization and digital technologies in sustainability research. This work further holds clear practical relevance, as it sheds light on data needs for value-retaining strategy support, thus serving as source of information for industry-driven DBP initiatives.

## Introduction

This paper provides empirical insights on data needs and requirements associated with digital battery passports (DBPs) in the context of end of (first) life battery management.

The research question answered in this paper is as follows:
RQ: What data needs and requirements has a digital battery passport to fulfil to support a sustainable and circular end of (first) battery life management?

The remainder of the paper is structured as follows: First, a brief theoretical background is provided. Subsequently, the applied methods are described, followed by presenting the results. Lastly, the discussion and conclusion are provided.

## Theoretical background

### *Circular and sustainable battery management*

When applying the concept of circular economy to the electric vehicle battery (EVB) value chain the most prominent value-retaining strategies discussed in literature are recycling and repurposing (Albertsen et al., 2021). Those strategies could contribute to reducing an EVB's negative sustainability impacts (i.e., environmental and social) as either the product itself is kept longer in the loop and may support electricity grid flexibility (Canals Casals et al., 2019) or respective secondary raw materials may substitute to some degree primary materials (Windisch-Kern et al., 2022).

However, to enable such strategies, respective value chain actors require access to data to support their processes and potential decision situations. For example, when considering the battery second life, respective actors require control over battery in-use data to identify suitable battery modules (Canals Casals et al., 2019). The recycler, on the other hand, would benefit from data which allows them to derive information about the EVB composition (incl. battery chemistry) (Windisch-Kern et al., 2022). Such data is currently not transferred between life cycle phases. Thus a DBP could enable such transfer whilst establishing smooth information flows along the EVB value chain (Berger et al., 2023).

### *Digital battery passports in sustainable product management support*

Due to upcoming legal requirements, DBPs have gained momentum over the last three years (European Commission, 2020). Consequently, many (mainly industry-led) initiatives (Battery Pass, 2023; Circulor, 2021; Global Battery Alliance, 2023) were launched to drive DBP development. Said initiatives, however, are showing rather limited consideration for a sustainable end-of-life management of batteries as there are either focusing on regulatory requirements (Battery Pass, 2023) or providing superficial (sustainability) information on batteries (Global Battery Alliance, 2023).

From a sustainability research point of view, literature on digital product passports (DPPs) is still rather limited (e.g., Berger et al., 2022, 2023; Ducuing & Reich, 2023; King et al., 2023; Koppelaar et al., 2023; Plociennik et al., 2022). The research focus ranges from theoretical and conceptual pieces (Adisorn et al., 2021; Berger et al., 2022; Koppelaar et al., 2023; Plociennik et al., 2022) to ones which provide first empirical insights into perceived DPP roles and purposes for sustainable product management (SPM) (King et al., 2023), as well as general data needs and requirements for DBPs for EVBs (Berger et al., 2023). The end of life phase of products, however, is currently underrepresented in DPP research.

## Methods

The employed research design comprised three stages which are described in further detail in the following subsections.

### *Stage 1: Semi-structured expert interviews*

Between October and December 2022, 12 semi-structured expert interviews were conducted. The participant recruitment was based on a knowledge resource nomination worksheet (KRNW) approach (Okoli & Pawlowski, 2004). Respective KRNW expert selection criteria were defined as follows: interviewees had to be affiliated with the battery end of life (EoL) and/or the second use (B2U). Furthermore, practical experience in the EoL or B2U field was desirable (e.g., EoL battery management and handling, B2U-related operations). Those connected to the life cycle stages of interest were also included. The profiles of interviewed experts can be found in Table 1 (EoL affiliated experts) and Table 2 (B2U affiliated experts).

| Expert ID | Organization type | Role within organization, expertise, country |
|---|---|---|
| EOL1 | University | Researcher<br>Experience in battery recycling processes<br>Years of experience: 7<br>Country: Austria |
| EOL2 | University | Researcher<br>Experience in battery recycling processes and life cycle assessment<br>Years of experience: 10<br>Country: Austria |
| EOL3 | Recycling center | CEO<br>Experience in battery recycling and second life<br>Years of experience: 5<br>Country: Germany |
| EOL4 | Manufacturer for recycling systems | Team lead R&D<br>Experience in development of battery recycling systems<br>Years of experience: 14<br>Country: Austria |
| EOL5 | Recycling center | CEO<br>Experience in development of battery recycling systems and second life solutions<br>Years of experience: 20<br>Country: Austria |

**Table 1. Profile of EoL experts consulted for the semi-structured interview series. EoL = end of life.**

| Expert ID | Organization type | Role within organization, expertise, country |
|---|---|---|
| B2U1 | University | Researcher<br>Experience in battery second life, energy storage systems, life cycle assessment<br>Years of experience: 7<br>Country: Spain |
| B2U2 | University | Researcher<br>Experience in battery disassembly and battery second life<br>Years of experience: 3<br>Country: Germany |
| B2U3 | Automotive engineering center | Engineer<br>Experience in battery pack design, E-Systems design,<br>Years of experience: 5<br>Country: United Kingdom |
| B2U4 | University | Researcher<br>Experience in policies about critical raw materials, circular business models<br>Years of experience: 10<br>Country: Sweden |
| B2U5 | University | Researcher<br>Experience in battery recycling processes and second life business models<br>Years of experience: 7<br>Country: Austria |
| B2U6 | Automotive engineering center | Engineer<br>Experience in battery systems design<br>Years of experience: 6<br>Country: Austria |
| B2U7 | Automotive engineering center | Engineer<br>Experience in battery state of health assessment<br>Years of experience: 4<br>Country: Austria |

**Table 2. Profile of B2U experts consulted for the semi-structured interview series. B2U = battery second use.**

The interview guideline was designed to gain knowledge about EoL and B2U actors' data needs for sustainable battery management support. Thus, they were presented with 20 pre-defined data points which were derived from a theoretical DBP concept (Berger et al., 2022). The interviewees were asked to classify those data points regarding their perceived importance (i.e., high to no importance) for supporting value-retaining strategies.

Furthermore, interviewees were asked to provide their perspectives on further data-related topics (e.g., perceived data accessibility and needed data granularity). The interviewees were further given the opportunity to provide additional data points (i.e., data points not being in the pre-defined list). It needs to be noted that some experts provided their perspective on both value-retaining strategies as they had respective expertise.

The duration of the interviews ranged from 30 to 120 minutes. For documentation purposes, audio recordings were made.

*Stage 2: Qualitative content analysis*

The audio material was transcribed (software: MAXQDA2022) and then subjected to a qualitative content analysis (Mayring, 2000). The coding system was created by one of the present authors in an iterative abductive coding approach. Thus, the coding system was adapted (i.e., by developing new codes, merging existing codes, deleting codes) based on discussions amongst the authors' research group.

*Stage 3: Synthesis*

The third stage comprised the synthesis of the derived qualitative content analysis results.

## Results

*Data needs and requirements: End of life*

Battery chemistry was identified as the most important data point for recycling support. Interviewees stressed that at least information about active material ratios are needed to support efficient recycling processes (incl. recycling process planning, managing waste streams, recovering battery grade secondary material).

As another data point of importance, "disassembly options and instructions" was identified, as this can help to support efficient battery pack disassembly at the recycler's location.

Furthermore, the data point "circularity performance" was classified with high importance due to legal requirements in the form of disclosure of recycling quotas.

Information about sustainability performances (in particular environmental performances) was classified with no importance for recycling process support. This classification was justified as such information would not influence the recycling process, as other factors (e.g., process efficiency, economic viability, recovery of battery-grade material) were emphasized.

The derived data point classification from an EoL perspective is depicted in Figure 1.

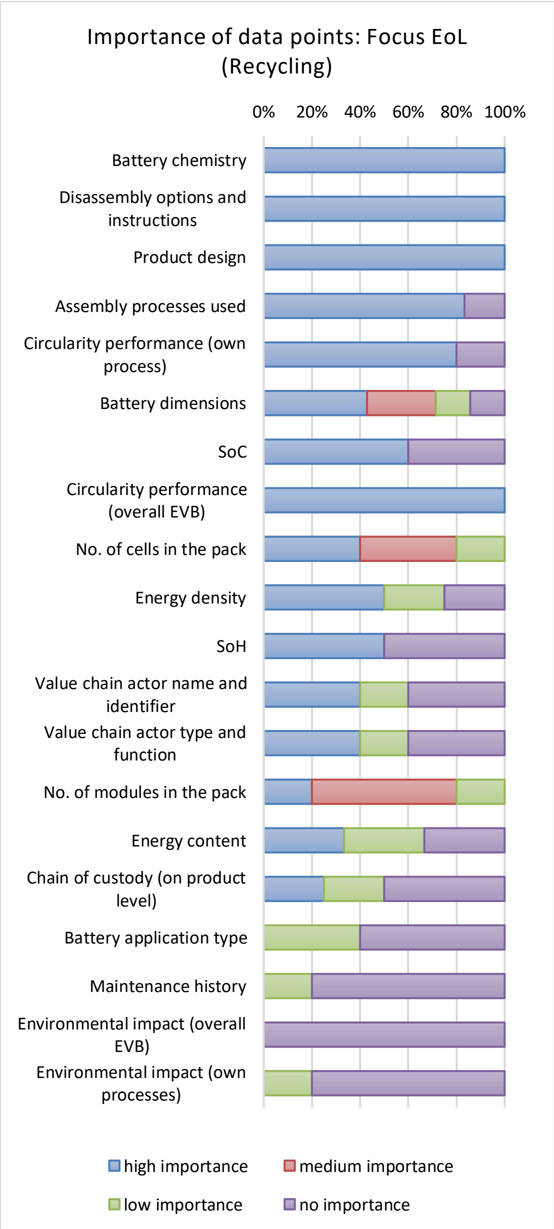

**Figure 1. Data importance classification from an EoL perspective. Source: Own depiction. EoL = end of life.**

*Data needs and requirements: Battery second use*

In a B2U context, participants emphasized the importance of having control over the EVB state of health (SoH) or even battery management system data (i.e., battery in-use data). The SoH was further stressed as the most important indicator to assess whether an EVB (module) qualifies for a B2U.

Furthermore, information about an EVB's maintenance history (i.e., maintenance triggers, maintenance work done) was classified as important as it might serve as additional information to support the identification of suitable EVB modules for a B2U.

Also, information on the "product design", in combination with "disassembly options and instructions" and "assembly processes used", was classified as highly important. However, the data point "disassembly options and instructions" received stronger attention as it may enable an efficient EVB disassembly.

The data point "environmental performance" was classified with low to no importance for B2U support. In this context, similar reasons as for recycling process support (i.e., information does not influence the decision whether a module enters a second life, focus on economically viable and efficient repurposing processes) were given.

The derived data point classification from a B2U perspective is depicted in Figure 2.

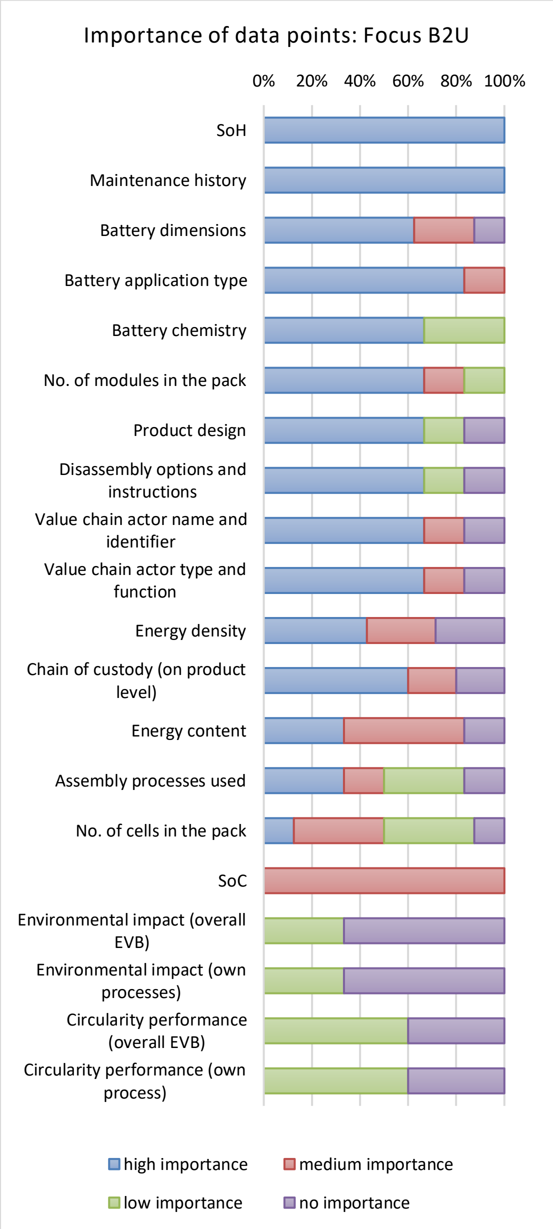

**Figure 2. Data importance classification from an B2U perspective. Source: Own depiction. B2U = battery second use.**

### *Data management challenges*

The qualitative material further allowed to identify perceived data management challenges. This particularly concerned the current inaccessibility of needed data for EoL and B2U support (see Figure 3). Considering prior mentioned data points, most of them were perceived to have a low accessibility. This was generally attributed to data gaps along the EVB value chain (see Figure 4). The most frequently mentioned reason for such data gaps was attributed to value chain actors affiliated with the beginning of life (BoL) acting as data gatekeepers due to the lack of data-sharing incentives.

Another pressing issue was identified in the form of lacking standardization of shared data. For example, the SoH was mentioned as an important indicator to support B2U. However, as of now there is no standardized assessment approach. Thus, SoH values cannot be easily compared to each.

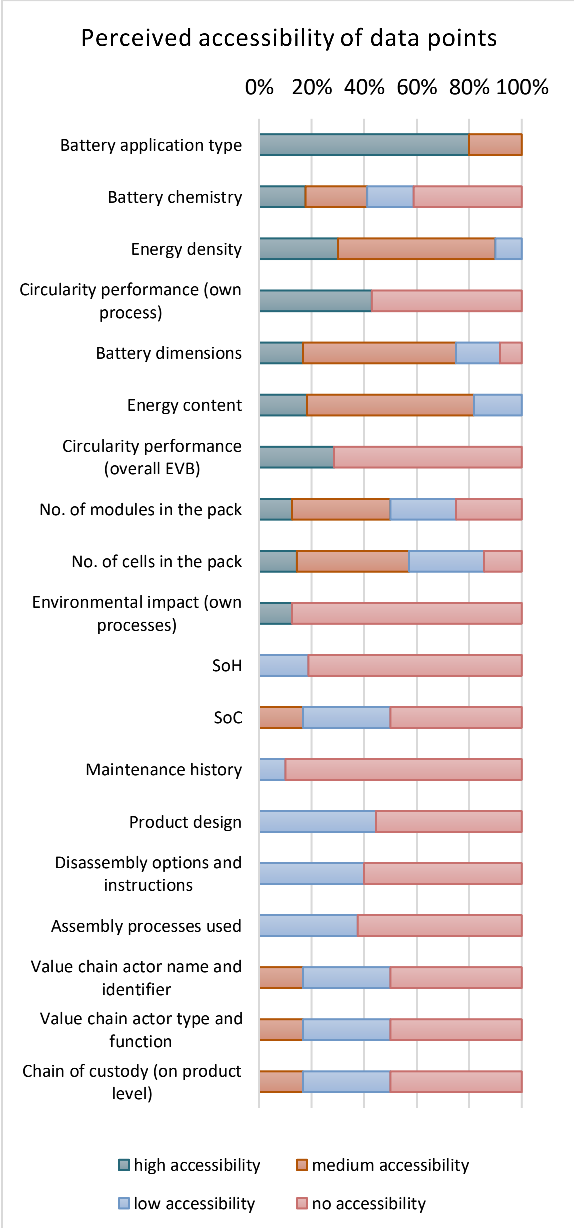

**Figure 3. By interviewees perceived accessibility of data points for EoL and B2U support. Source: Own depiction. EoL = end of life. B2U = battery second use.**

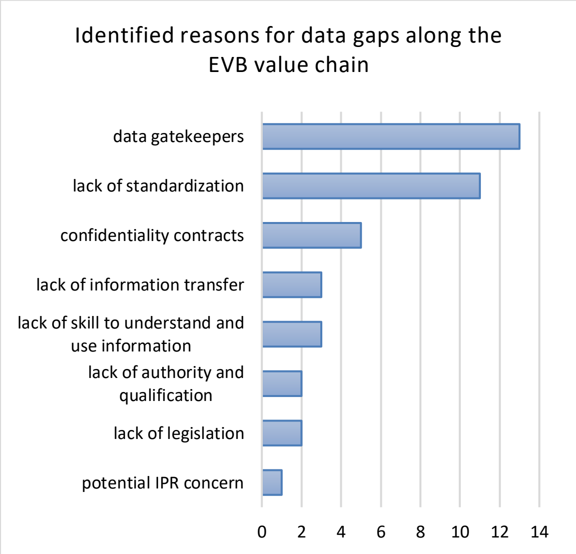

**Figure 4. Frequency of identified reasons for data gaps along the EVB value chain. Source: Own depiction. EVB = electric vehicle battery.**

Regarding data gatekeepers, experts further provided reasonings why, in particular, BoL-affiliated actors are currently acting as such (see Figure 5). In this context, competitive concerns of BoL actors were often voiced as needed data for EoL and B2U support (e.g., battery chemistry, battery in-use data) are linked to the valuable asset "battery". Furthermore, strict confidentiality contracts were brought up as an issue for not sharing data. In addition, two somewhat related themes in the context of (lacking) data sharing were identified: "no good reason to share" and "lacking legal pressure", as participants stated that value chain actors only share the data which they have to share, or perceive benefits (e.g., business case).

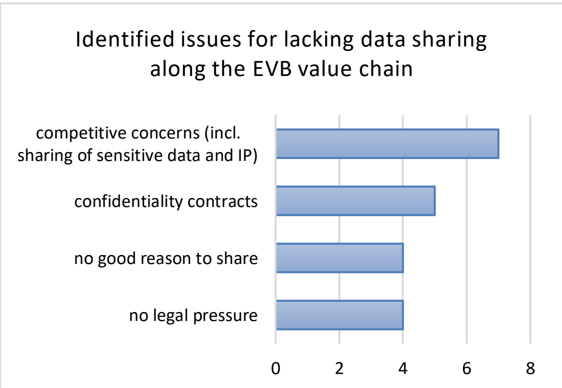

**Figure 5. Frequency of identified reasons for lacking data sharing along the EVB value chain. Source: Own depiction. EVB = electric vehicle battery.**

## Discussion

### *Data needs for sustainable end of (first) battery life support*

When comparing the most important data point for recycling support (i.e., battery chemistry) with the one for B2U support (i.e., SoH), the results highlight the difference in value chain actors' data needs. Those differences are plausible as those value chain actor groups pursue different core tasks. Consequently, it can be argued that a holistic understanding of value chain actors and their roles in the value chain is required when defining the data content of a DBP for circular and sustainable EVB management. Otherwise, one would forfeit a DBP's potential to enable sustainable and circular value chains if data needs of certain value chain actor groups were to be neglected. When considering a DBP as a tool to improve the sustainability performance of the EVB value chain, derived results might question the need for such information on a DBP. Nevertheless, the need for data on sustainability performances (e.g., on the battery itself and recycling and repurposing processes) should not simply be dismissed as the perceived importance can change over time. Firstly, upcoming legal incentives may contribute to such a change. This could be observed for the data point "circularity performance" as, in particular, EoL-affiliated experts stressed legal requirements in the form of recycling quotas. Hence, directions provided by policymakers and legislators may initialize a shift in the perceived need for such information for process support. However, it needs to be stressed that still, a holistic view for sustainability impact assessment is lacking as current legal frameworks incentivize value chain actors to pursue one single indicator only (e.g., carbon footprints). As interviewees emphasized the need for efficient and economically viable processes, potential eco-efficiency gains could be brought to their attention by taking into consideration sustainability performance information. For instance, by considering sustainability data, they could achieve cost reductions through process energy demand optimizations and emission reductions, thereby decreasing carbon tax liabilities. Such incentives could represent the initial step in fostering a mindset shift towards incorporating sustainability considerations into decision-making processes.

*Digital battery passports and the role of data gatekeepers*

The results further highlight which data points were perceived as accessible or rather inaccessible to EoL and B2U-affiliated actors. This concerned, in particular, those data points which were classified as highly important for recycling and repurposing support. The inaccessibility of data points needed was, in general, attributed to the existence of data gatekeepers, thus value chain actors who do currently not actively support the data transfer between life cycle phases (e.g., between BoL and EoL or B2U). Consequently, it can be argued that if a DBP were to be currently deployed, it could not support the transition towards more sustainable and circular value chains due to such data gatekeepers. Regarding possible explanations for BoL actors acting as data gatekeepers, the fear of competitive drawbacks (cf., Berger et al., 2023) as well as “not having a good reason to share data” (e.g., no legal pressure, no business case or other benefit perceived) was oftentimes brought forward. This, in turn, mirrors a rather traditional mindset in which a focal organization is orchestrating a value chain. Considering such a mindset it is plausible to not transfer data to third parties as they could potentially reap benefits (e.g., in the form of business cases) from the combination asset (i.e., battery) and data. However, when aiming to pursue more circular and sustainable value chains, collaboration is a prerequisite (Albertsen et al., 2021). Such collaboration could be facilitated by a DBP if data sharing were to be incentivized by policymakers and regulators. Thus, they have to be aware of (a) data needs of EVB value chain actors as well as (b) data management challenges (e.g., reasons for data sharing reluctance) to provide respective data sharing directions.

## Conclusions

This paper provided empirical insights in data needs and requirements DBPs need to fulfil support a sustainable end of (first) battery life. In particular the inaccessibility of data needed to EoL and B2U affiliated actors revealed in this study is of great concern as the transition towards more circular and sustainable battery value chains is aggravated as a consequence. Thus, further research is encouraged regarding data management challenges and ways to resolve them (in particular with focus on data sharing incentives).

# Chair a Story – What Repurpose-Driven Design can contribute to upcycling more dining room chairs

**Moa Berglund[a], Sofia Bystedt[b], David Eklöf[a], Martijn van den Bosch[a], Renee Wever[a]**
a) Linköping University, Product Realisation division, IEI department, Linköping, Sweden
b) ReTuna Återbruksgalleria och konferens, Eskinstuna, Sweden

**Keywords**: Repurpose-driven design; Material-driven-design; craft; upcycling; circular economy.

**Abstract**: ReTuna Återbruksgalleria is a mall in Eskilstuna, Sweden, entirely dedicated to second-hand products. Goods are being donated continuously. Daily, the different entrepreneurs in the mall get to select products from the new donations. They then sell them as-is, or repair, refurbish, or repurpose the products. Products that are not selected by the entrepreneurs for a week are re-directed to material recycling and/or energy recovery.

Both by numbers and by volume, dining room chairs constitute a substantial part of the flow through ReTuna. Many of these chairs are technically fine, but aesthetically out of fashion or slightly worn. The number of donated chairs is much higher than what the entrepreneurs in the mall can take care of and sell. Hence, a substantial percentage of functioning chairs goes to low-level end-of-life treatment.

In repurposing or upcycling, the previous life of products and materials is treated as a value. Reclaimed materials have a story to share. In the current project, we explore how designerly explorations of the dining room chairs might help to re-direct them to higher-value applications. We use a repurpose-driven design approach, which is an adaptation of material driven design.

The design research approach consists predominantly of two explorations: Returslöjd (ReCraft) which is a workshop (three sessions of three hours each) where 8 skilled participants used craft techniques and reused materials to upcycle worn chairs. The other approach is based on material from disassembled chairs and products made by repurposing the material. Results were shown during an interactive pop-up exhibition at the ReTuna mall. The aim was to solicit opinions and emotional responses of the shoppers at ReTuna mall for two weeks. These insights of both approaches are then translated into findings and potential designs.

## Introduction

The latest Circularity Gap Report indicates that the world economy is only 8.6% circular (Circle Economy, 2022). To increase circularity, we will need the full range of strategies: re-use, re-distribute, refurbish, repair, repurpose, and recycle. Repurpose, certainly at large scales, is the one strategy in this row that is least explored academically (Lepelaar, et al 2022).

In repurposing or upcycling, the previous life of products and materials is treated as a value. Reclaimed materials have a story to share (ibid). In the current project, we explore how designerly explorations of dining room chairs might help to re-direct them to higher-value applications. We use a repurpose-driven design approach (Lepelaar, et al 2022), which is an adaptation of material driven design (Van Bezooyen, 2014, Karana et al 2015, Van Boeijen et al, 2020, p.75).

Our study was executed at ReTuna Återbruksgalleria, which is a second-hand mall in Eskilstuna, connected to a recycling station. ReTuna started in 2015 and has been growing since. The mall houses an array of shops/entrepreneurs (currently 14) that base their business on donated products. At ReTuna, people can donate products they do not need or want anymore and give them a new life. The first stop for all donated products is a place called 'Returen' (Returns). The staff at Returen sort the products and make a first selection of the products that are in good condition to reuse. The entrepreneurs/ shops in the mall then get to choose form those products, to reuse and/or upcycle them in their businesses. Objects that are not selected by the entrepreneurs are diverted on Thursdays to material recycling and energy recovery.

ReTuna is the world's first upcycling mall and is seen as an inspiration and a leading example both internationally and nationally (About us - Retuna, 2021, https://www.retuna.se/om-oss/).

## The ReTuna eco-system

Observations help designers to understand a specific situation and how the people involved are working (van Boeijen et al., 2020; Wiberg-Nilsson et al., 2021). This method was used in the first step of the research phase, to understand the reality at ReTuna. Observations were supplemented with semi-structured interviews with different actors in the ReTuna ecosystem, including multiple entrepreneurs who have their business in the mall.

The observations were done by working together with the employees during five days, but in a role of observing and counting furniture and understanding the flow of products. Notes and information collected during the five days was written down on the back of the template and transcribed to a digital document by the end of each day. In the end of the week, all the notes from the observation were printed out, and analysed together with the filled in templates. All the entrepreneurs who have an enterprise in the mall are welcome to pick furniture in *Returen* everyday between 09.30am and 10.00am.

An important tool in *Returen* is *plocklistor* (the Wish Lists), which is used to help the workers in Returen to understand what type of products the different businesses want to have and what is included in their businesses. The Wish List helps the entrepreneurs and the people working in Returen to sort the products and get them to the right place.

In a previous study at ReTuna Återbruks-galleria, Madelene Svensson (2021), found that 49 percent of the furniture that comes into *Returen* at ReTuna for upcycling and reuse actually goes on to the Recycling centre and thus to material recycling and energy recovery.

## Case Selections: Chairs

Based on the result from the observation, interviews with actors, discussions, and reflections, dining room chairs were selected as the focal product. This is based on the following insights:

- Chairs are the type of furniture that comes in and gets thrown away at the highest volumes.
- It is difficult to store chairs for a longer time and to sell chairs when there are uneven numbers, which is commonly the case.
- Chairs contain materials that can be transformed into something else, namely wood, leather, metal parts, screws, etc.
- The inflow of chairs is bigger than the number of chairs being sold, and therefore a lot of the material in the product goes to incineration or material recycling.
- Since chairs often consist of more than one material, the whole chair often goes to incineration instead of material recycling.

**Figure 1. Typical selection of dining room chairs at *Returen*. Category 1, 2 and 3. (Berglund, 2022).**

Our objective thus became: Find a way of how chairs can be upcycled or repurposed to increase the number of products staying at ReTuna mall instead of going to the recycling station.

One of the most important things while working with reuse of products is the sorting and categorisation of the products. Based on our pre-study we distinguish three categories.

**Category 1:** Old chairs with good quality, but some parts are worn out. One of the chosen products for our study in this category is produced by the company TON Chairs. A set of six similar chairs were coming in to *Returen* and were going to be thrown away. The Company TON aims to produce hand crafted chairs with good quality. The selling price for these chairs is between USD 100 and 300.

**Category 2:** Chairs that were trendy and modern a few years ago, that now are coming in in high volume and are still in good shape, but no one wants to buy them. Again one is selected for our study. This chair is composed of more than one material, wood and fabric, which result in the incineration waste container.

**Category 3**: Broken chairs are included in this category. This includes incomplete chairs (Fig 1), as well as chairs with for instance cracked seats. Even if the chairs are broken, they consist of materials that can be used in new products. There are a lot of different models of chairs in this category. (see Figure 1)

## METHODOLOGY AND INTERMEDIATE RESULTS

To explore how the chairs in the different categories can be repurposed and upcycled two different approaches are proposed.

For the chairs in category 1 an approach based on craft workshop was used to explore how chairs can be upcycled in different ways and therefore increase the value.

### Approach 1: Workshop - upcycling and crafts

The workshop was based on three sessions; each three hours long and held during three evenings in March. Eight participants from a craft course at ReTuna called Returslöjd (=ReCraft) participated in the workshop. The starting point for the first session was to use six identical chairs, and some other chairs from category 1 were also used.

The purpose of this workshop was to understand and document how worn-out chairs with good quality can be upcycled and get new value in different ways. By letting eight people with a lot of knowledge and experience about different craft techniques work with the chairs. The purpose was to gather knowledge together in the group, to learn from each other and to increase the value of the chairs. An observation of how the participants was working and how long time the different steps took was documented.

### Results: Workshop Retursløjd

Eight different chairs were upcycled during the workshops at ReTuna, during three Thursday evenings. Five of these chairs was the TON chair model and one was kept in its current condition to demonstrate the transition. (see Figure 2)

Embroideries from the storages in *Returen* became an inspiration for the upcycling of the chairs.

Only one of the five participants working with the TON chair model decided to repaint the wooden parts. This is a result of not having that much time. According to employees at IKEA second hand, that is the hardest part to create new value for chairs and sell it. It takes time to repaint chairs, which means that the price needs to be higher, but the customers are not willing to pay the true price that it would result in.

**Figure 2. The craft upcycling of category 1 chairs. (Berglund, 2022).**

### Approach 2: Material Driven Design (MDD)

Material Driven Design (MDD) is about having the material as the main driver for the development of products and design concepts, starting from understanding the material. This section is based in the method MDD. This method is usually used for new-coming materials that needs an area of use (van Boeijen et al., 2020). The aim is to us the MDD method in this project but adapt it to explore the potential of using already existing products as the main driver in the product development.

The four main steps in MDD were used in this approach together with the chairs from category 2 as material input. This section refers to the steps Material Driven Design (Karana et al., 2015). The aim with the process was to have MDD as a starting point and to document thoughts and challenges in each step, which afterward was summarized and analysed to an adapted method, Repurpose-Driven Design.

**Step 1 – Understanding the material, and product**
This step is about understanding the material you have. Understand the why. Take it apart, feel it. Figure 3 shows all the materials that one of the chairs in category 2 consist of.

The next part of this step is to sort the material in different material categories, it is preferable to collect more of each material, for example in this case using three chairs. The properties of the materials were analysed and for example oak, which some of the parts are made from, is rot-resistant and resistant to moisture.

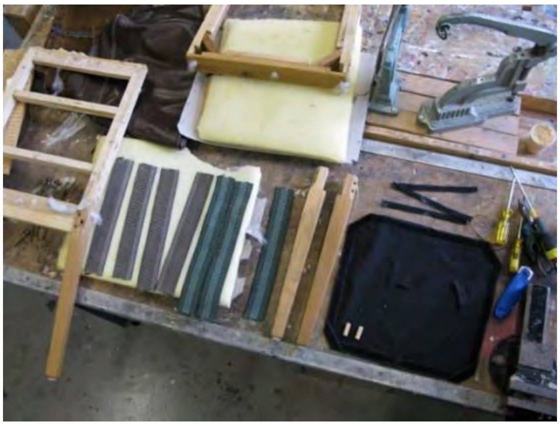

**Figure 3. All the materials that one of the category 2 chairs consist of (Berglund, 2022).**

**Step 2 – Create a vision, understand where you want to go**
In this step, the result from step 1 was further explored by brainstorming about what to do with the material. By organising a workshop with other people this could create more ideas. In this step brainstorming by sketching was done.

**Step 3 – Understand how you can get to your vision by using the material you have**
In this step a deeper understanding of the material is needed. What are the strongest parts of the collected material? To clarify this step, it was helpful to talk with different experts. In this step it was important to refresh and clean all the material parts, and after that start exploring by saw and break up the material. How the parts can be used in different products to maximize the value was analysed in this step.

**Step 4 – Creating material (or product) concepts**
The result from step 1-3 is turned to reality in this step. Create the concepts from the information gathered about the material and its properties. In this step it is important to think about new flows, can someone else use the material that cannot be used in this concept?
Start building and testing, in this case the parts from the dining chairs were transformed into different products.

**Results of Material Driven Design**
By following the steps described and exploring the potential in the material that a chair from category consist of, different products were put together. The game in Figure 4 is one of the results from using the different steps.

**Figure 4. the Kubb game made out of re-purposed dineing room chairs. (Berglund, 2022).**

The process of transforming a worn-out dining chair to other products with support from the steps in MDD was instructive. The thoughts that came up during the process and each step was documented. This process led to the approach Repurpose Driven Design (RDD).

One of the most important findings from doing this process was that the previous product and its history helps to decide the design and appearance for the new product. This can be both a challenge and a helpful direction. In this case the Kubb-game was created in the way it is because of the markings in the wood parts from all the staples. The 'King' is made from the biggest parts found in the frame of the chair.
The products were tested by playing the game and using the bag which created discussion and thoughts. The game got positive feedback, one of the test persons clarified that it was working perfect, it was fun that the parts looked a bit different, more fun to play than a newly produced game and that it was unique (Test person, personal communication, April 23, 2022).

**Validation: Pop-up exhibition at Retuna**
To validate and evaluate the two different approaches, collect data and share the survey, a Pop-Up event and exhibition was held. The exhibition was conducted at ReTuna Återbruksgalleria, on the second floor, in the corridor outside the stores during 3 weeks in April. The name of the exhibition, *Chair a Story* is based in storytelling and to rethink the value in chairs. (see figure 5)

To connect the parts in the exhibition a survey was made, to collect data and get a greater understanding of the user. It was tested and evaluated and reformulated before using it. In total there were 30 people who answered the survey and many of the visitors was just looking at the exhibition and talked about what they saw.

QR-codes were placed on different places to easily access the survey from mobile phones.

**Figure 5. the pop-up exhibition. (Berglund, 2022).**

To add extra information for the visitors, small labels with a story and information about the person who renovated it were placed on each chair.

**The interaction with visitors**
The goal of the exhibition was to understand the user and customer, get feedback and observe visitor reactions. Therefore, findings and reflection from being present at the exhibition during some of the days and observing and talking with people are presented below:

- A lot of interest from people looking at the exhibition
- People are getting happy when looking at the upcycled chairs, a lot of colours and craft which inspires.
- People likes that there is an inspirational exhibition in this place at ReTuna and think that it should be different kinds of inspiration there all the time. A nice way to get upcycle and repair ideas.
- People got curious.

The main insights from analysing the survey and all the collected answers from people is presented in this section. In total 30 people answered the survey.
A main drive for people to buy second hand and something that people think is important to know, is that climate impact of the product less compared to a new product. The main findings connected to storytelling are presented below:
Question: *What information do you take with you after looking at the renovated chairs? Choose two options that feel most important for you to know.*

- 27 out of 30 people choose the option: To know that the chairs have been saved from being thrown away.

**DISCUSSION & CONCLUSION ON DESIGN RESEARCH PHASE**
We have shown that it is possible to create more value by using craft and already produced materials. Using MDD resulted in some different products and concept. Even though it is a repurposed product, it is important to make sure that the products will last, by testing it and get feedback. Challenges with using the MDD for already produced material in products is that you need to be flexible and focus on the shape and properties of the product as your starting point. The way the MDD method was used in the concept phase of the project was not structured in a linear way all the time. The

process went back and forth between the steps to understand how they could be adapted towards repurpose driven design.

In this case, different tools and machines were used, saw machines, cross-cut saw, and drill. These are machines that usually exist in common workspaces. To do an interactive pop-up exhibition was a great way to get input in this type of project. It was a fun way of get to talk to different people and get feedback on the different products.

## FINAL APPROACH FOR REPURPOSE AND UPCYCLE DRIVEN DESIGN

Based on the result from the exhibition Chair a Story, the different parts of Approach 1 and the process of Approach 2, a final approach was developed.

Preparation starts from the step 0 when the product is seen as waste and is on its way to the end of its life. But waste is just resources on the wrong place. Is it broken, at the wrong place, a coincidence, or an accident? (still step 0).

Evaluate your findings from the Preparation & Understanding and start to either upcycle or use the Repurpose Driven Design method.

When doing Step 0 the first question to ask is: Can the product be upcycled to increase its value? If the conclusion is Yes, the steps presented in Figure 6 can be followed. The steps work as short guidelines to help increase the value for the product. For example, when identifying category 1 of old quality dining chairs, a decision was made to upcycle them instead of disassembling and use RDD.

Based on the process of using the Material Driven Design method to create new products from already existing products, the steps 1-4 presented in this section have been developed. Here, the seminar about the report Repurpose Driven Design and Manufacturing, a research project done at Amsterdam University of Applied Sciences (Lepelaar, et al 2022) was part of the inspiration.

How can the concept that has thus been created in steps 1-4 stay in the loop? This question needs to be explored in the final step. Another part is to imagine and research how the concept can be scaled up, and what production techniques can be used. Regarding marketing: tell the truth about the production and materials, show how it's done and what is reused and what is not, be open and share with others.

**Figure 6. repurpose-driven design. (Berglund, 2022).**

# Incorporating social lifecycle assessment in circularity metrics to avoid the unintended consequences of circular economy

**Anubhuti Bhatnagar [a], Kirsi Niinimäki [a]**
a) Department of Design, Aalto University, Otakaari 12, Espoo, FI-02510

**Keywords**: Social hotspot analysis; Life cycle assessment; Circularity framework; Research trends; resource recovery.

**Abstract**: A sustainable transition towards a circular economy requires that businesses evaluate their environmental, economic, and social impact. Since there has been a limited effort for identifying the social impacts of businesses, social life cycle assessment (SLCA) was developed. In this paper, 44 peer-reviewed articles that reported the social consequences of a circular economy transition were identified and reviewed. The review shows that a circular transition may have negative consequences in waste recovery and recycling due to existing unfair labor practices in this sector or create social risks during material substitution, technology scale-up, or changes in the supply chains. However, uncertainty exists in the results because SLCA does not have a uniformly accepted methodology for data collection and analysis, which hinders the comparability of linear and circular economies. Researchers suggest that better stakeholder mapping, reviewing data collection techniques, and creating consensus-driven standard indicators will improve the social assessment of the circular economy.

## Introduction

Only 7.2% of the material input in the global economy is recovered (Circle Economy, 2023). Hence, businesses are being encouraged to incorporate circular economy (CE) in their operational framework by changing the materials used in manufacturing, evaluating the impacts of the products across the life cycle, promoting end-of-life responsibility, and creating policies for CE transition.

Evaluating circularity requires tools that may track, monitor, and measure the degree to which the CE-promoting strategies succeed. The environmental life cycle assessment (ELCA) tool (ISO, 2006a, 2006b) is used to assess the environmental performance of a CE transition. Other tools are Material Flow Analysis (Foglia et al., 2021) and Input-Output Analysis (Shi et al., 2019). Based on these, the resource potential indicator, global resource indicator, and longevity indicator were developed to quantify resource recovery and recycling and measure the duration to which the material remained in the supply chain (Corona et al., 2019).

Despite the benefits, negative consequences of CE arise when governments or businesses are unaware of the less visible social impacts (Shaikh et al., 2020). A systematic evaluation of social impact across a product's life through the social life cycle assessment (SLCA) tool may reduce the negative impacts of a CE transition. SLCA was first discussed in 1996 as a complementary tool to ELCA, but at the time it only focused on the impact on human health (Arvidsson et al., 2015). This focus later expanded to include other indicators such as worker rights, protection of the indigenous population, and societal economic development. The first systematic guidelines for SLCA were developed by the United Nations Environment Program with the Society of Environmental Toxicology and Chemistry in 2009 (UNEP, 2009) and revised in 2020 (UNEP, 2020). Hereafter these will be referred to as the 'UNEP guidelines.' Another approach to measuring social impact was published in the Handbook for Product Social Impact Assessment (Goedkoop et al., 2020). This guideline is a consensus-based practical approach proposed by industrial stakeholders.

**The present paper identifies the social risks of CE transitions in various industries, the role of SLCA in evaluating these risks, and makes recommendations to improve the assessment.**

## Methods

Two keyword searches shown below were performed using Web of Science ™ to identify papers related to SLCA and CE published between 2009 and December 2022:

a) "Social LCA" OR "social lifecycle assessment" OR "social life cycle assessment" (Topic) and English (Languages) and Article or Review Article (Document Types): 394 outputs
b) ("circular economy" OR recycle OR refurbish OR reuse OR recover OR circularity) AND "social impact" (Topic) and Article or Review Article (Document Types): 148 outputs

Excluding duplicates, the remaining 406 articles were sorted into 'review,' 'methodology development,' 'case study,' and 'methodology development with case study.' Further delving into the abstracts of the case studies showed that only 44 articles reported social impacts of a CE transition or CE-related concepts such as reduce, reuse, repair/ refurbish, recycle, and recover. A list of these articles is provided in the appendix.

## Results and Discussions

*Classification of case studies*

Figure 1 shows the historical growth in the number of publications regarding SLCA and the cases which incorporate social assessment in a circularity framework. Over 70% of these have been published between 2018 and 2022. The industrial classification (based on the United Nations, 2008) of these studies shows (Figure 2) that waste collection, treatment, and material recovery have been the focus of most case studies.

Many case studies used the UNEP guidelines (UNEP, 2020) to evaluate social impacts on six key stakeholders— workers (W), local communities (LC), value chain actors (VCA), consumers (Co), children (Ch), and society (S). Figure 3 shows that workers are the most frequently evaluated stakeholders (33 cases), and researchers find health and safety to be important social issues because the recirculation of materials imbibes new risks for workers (Shi et al., 2019). However, in some cases, social impact has been assessed using methods like externality assessment (Blanc et al., 2019) or human-scale development (Clube & Tennant, 2022). The list of stakeholders and impact categories was also expanded to assess specific supply chains and is listed in Table A1.

Creating an inventory for SLCA is the most crucial step for the assessment for which the data was collected through primary, secondary, and mixed methods. Primary data collection involved structured or semi-structured interviews with stakeholders (Aparcana & Salhofer, 2013) or questionnaires for key members of the supply chain (Shaikh et al., 2020). Secondary data collection involved regional databases, technical reports, scientific publications, and statistical databases (Foglia et al., 2021; Yıldız-Geyhan et al., 2017). Expert interviews also helped identify the potential social impacts of technologies in the design or pilot phases (Opher et al., 2018). Mixed methods used a combination of primary and secondary collection techniques, such as a stakeholder survey, technical report, or regional database.

### *Status of social sustainability in the CE transition*

*Consequences of circular economy*

Promoting circularity in supply chains may be a practical alternative to the resource-intensive methods of industrial production but the choice of a circular strategy may not always be clear. For instance, Suckling & Lee (2017) suggest that mobile phones can be either recycled at the end of first life (EoFL) or reused at EoFL followed by recycling. At EoFL, recycling prevents landfilling of hazardous waste, promotes material recovery, and removes the social and environmental burden of raw material extraction. But additional components have to be produced to replace the discarded product. Reuse at EoFL provides access to the technology to a second user and prolongs product life. However, phones are generally reused in countries with poor waste management systems that create health and environmental risks during the recycling phase (Umair et al., 2015). In this section, the consequences of several other CE transitions are discussed.

*(a) Positive consequences*

Nineteen of the cases reviewed had positive consequences, i.e., the benefits accrued for society and the environment, and the CE transition was economically viable. Several of these cases were concerned with using a closed-loop recycling technique to recover and reuse material from a single waste stream to create the same initial product. Recycling and reuse of waste materials have been found to improve working conditions and reduce exposure to toxins in plastic (Lukman et al., 2021), glass (Mansilla-Obando et al., 2022), and paper (Zerbino et al., 2023) production. Foolmaun & Ramjeeawon (2013) found that a combination of recycling (75%) and landfilling (25%) was socially and environmentally optimal. Public engagement regarding the management of plastic waste (particularly PET) further improved the waste collection rate and consequently improved the recycling rates (Bianchini & Rossi, 2021). In the textile sector, using waste sheep wool in Sweden reportedly halved the environmental impact of sweater production and reduced the social risks related to sourcing wool from outside the EU (Martin & Herlaar, 2021). In the construction sector, material substitution through the use of recycled concrete aggregates (Hossain et al., 2018), lime ash from the pulp industry for clinker (Simões et al., 2021), and bio-based alternatives (Barrio et al., 2021) reduced social impact on the recyclers, producers, and local communities. Regarding mixed waste streams such as municipal solid waste, Di Maria et al. (2020) reported that separating waste streams like bio-waste, paper, metals, and glass followed by material recovery reduced global warming potential, particulate matter emissions, resource depletion, acidification and eutrophication potential, and generated thousands of new jobs.

*(b) Negative or mixed consequences*

In 19 of the cases reviewed, the CE transition had negative social, environmental, or economic consequences. The closed-loop recycling of non-beverage high-density polyethylene bottles was found economically prohibitive due to the energy costs associated with material transformation despite the social benefits (Papo & Corona, 2022). Recycled aggregates reduce the impact on human health, the environment, and the costs of road construction, but have a higher economic and environmental burden during the use phase because the rougher texture of the roads increases fuel use and tire breakdown (Shi et al., 2019). The bio-based alternatives for food packaging were also economically unsustainable till greater production efficiency is ensured despite the reduced impact on climate change, pollutant emissions, and health risks for the cultivators (Blanc et al., 2019).

Other cases related to single waste streams showed that despite the environmental benefits, there were several negative impacts on stakeholders. For example, recovering phosphorous during agricultural activities in Japan reduced material import requirements, but adversely impacted gender equality since Japan showed higher workplace discrimination than other phosphorous producers like China and Morocco (Teah & Onuki, 2017). Organic waste from agriculture also showed potential to establish a new market for organic fertilizers, create new jobs, save working time, and reduce a crop's water use requirement, but these strategies require upskilling of the workers so that they can operate the technology and may expose LCs to harmful emissions from the use of organic fertilizers (Andrade et al., 2022). In another case, magnesium was recovered from the wastewater treatment plant in the Netherlands leading to increased self-reliance in Dutch society but leading to job loss for the primary magnesium producers working in Russia (Tsalidis & Korevaar, 2019). Regarding mixed waste stream, the benefits of treating MSW as a single waste stream for electricity production were dependent on the plant's location and were only competitive at a threshold waste generated and electricity substituted (Nubi et al., 2021).

Negative social consequences of waste recovery such as unregulated working hours, poor social security, discrimination, lack of adequate health benefits, and loss of unskilled jobs are also prevalent when informal workers are engaged in waste management (Umair et al., 2015). Regulatory intervention such as formalizing recyclers and safeguarding worker rights under government legislation has not shown enough benefits in low-income countries since formal recyclers were given short-term contracts that did not ensure social benefits or prevent discrimination (Aparcana & Salhofer, 2013). Replacing manual collection with urban collection centers led to significant environmental savings but also led to job losses for the disabled or low-skilled workers engaged in manual waste collection (Vinyes et al., 2013). It may be argued that manual waste collection promotes health risks due to exposure to toxic substances during waste collection and the compensation may not meet the economic requirements. Hence, Yıldız-Geyhan et al. (2017) showed that in a combined informal-formal scenario waste collectors' social security, health and safety may be legalized and safeguarded although the number of collectors employed was significantly less than in an informal sector.

Other consequences of a CE transition were related to regional-level transformation, such as finding a sufficient labor force to take over the skilled jobs created during the CE transition and limited consideration of inputs from citizens and civil society compared to companies and the municipal government Vanhuyse et al. (2022). Mohaddes Khorassani et al. (2019) reported that a refurbishing initiative undertaken by the local government to restore a heritage site created mixed impacts, with some environmental impacts related to the reconstruction and use phase and positive benefits for society.

## *Promoting social assessment of CE*

*Challenges of SLCA tool*
Addressing the challenges of using the SLCA tool is necessary to evaluate the social sustainability of a CE transition. The challenges regarding the use of the SLCA tool that were identified in the cases reviewed in this paper are listed in this section.

(a) Utility: Several small and medium companies that operate with local suppliers can ensure open communication regarding social risks and do not find utility in performing a formal social assessment (Walker et al., 2021).
(b) Validity: SLCA practitioners report that establishing the validity of data collected is challenging in informal sectors where stakeholders are uncomfortable in responding honestly either due to fear of losing their jobs (Shaikh et al., 2020) or receiving poor social responsibility ratings (Barrio et al., 2021). Further, regional databases do not adequately assess the social impacts of specific supply chains (Teah & Onuki, 2017).
(c) Comparability: Several SLCA sub-categories have multiple interpretations making a comparison challenging. For instance, the creation of jobs is considered a 'positive impact' when considering a regional CE-transition (Vanhuyse et al., 2022) but for regional waste collection program, the CE-transition that led to most jobs was harmful to the environment (Vinyes et al., 2013). SLCA results are incomparable when a circular supply chain is significantly different from a linear supply chain due to changes in the number of stakeholders or organizations involved (Tsalidis, 2022).
(d) Completeness: More than one study reported that the provided sub-categories and stakeholder categories in the UNEP Guidelines were insufficient for the assessment (See section 3.2). SLCA also cannot capture the product's "use phase" despite its significance in extending the product's lifetime through options like repairing or reusing (Suarez-Visbal et al., 2022). In addition, it is still not clear how to assess the potential social impact of materials with multiple life cycles in terms of impact attribution across the various life cycles (Papo & Corona, 2022).

*Recommendations for improving SLCA*
Based on the consequences of CE and the challenges of using SLCA, several recommendations have been made to better incorporate social sustainability in the CE transition and promote the use of SLCA tools.

1) Stakeholder engagement: A step-by-step approach for defining the boundaries and moving through stakeholder identification, mapping, and monitoring, using stakeholders and experts may narrow the scope of the SLCA (Vanhuyse et al., 2022) and help identify what generates additional social value in a product-specific context.
2) Standardizing indicators: Standard indicators should be created based on the global consensus of socially relevant themes such as the Sustainable Development Goals (Herrera Almanza & Corona, 2020) or through collaboration with businesses regarding context-specific requirements (Walker et al., 2021).
3) Reliability: The quality of the stakeholder responses should be checked using a scoring system, which calculates average scores from individual stakeholders by

corroborating the response with available reports (Zerbino et al., 2023). In general, the global databases for secondary data collection (like PSILCA or EcoInvent) need to be expanded continuously with more localized case studies.

4) Improving comparability: It is recommended to create normalization and weighting factors to categorize the social impacts of the organizations. Kühnen & Hahn (2019) suggest that developing an expertise-based consensus on these factors may promote the use of SLCA.

## Conclusions

There has been a steady increase in the publications evaluating social impacts of circular transition in industries. In this review paper, 43% of the cases studied reported that these transitions are socially, economically, and environmentally sustainable. However, an equal number of cases reported negative impacts on one of the dimensions of sustainability. Especially during material recovery and reuse many stakeholders face health and safety risks or job losses. There are also environmental impacts due to energy used in restoring the recovered material's quality for reuse. Further, data collection for SLCA and impact assessment remain challenging. Hence, many researchers recommend the use of a scoring system to assess the quality of stakeholder responses when primary data is used, expand the global databases to include more site-specific cases and develop weighting factors for comparing linear and circular economies in terms of their social impacts.

**Keywords**: Design; Reusable Packaging; Packaging Systems; Reuse; Circular Economy; Sustainability.

**Abstract**: Reusable packaging systems (RPS) are increasingly explored as an alternative to single-use packaging. Current research lacks focus and direction. This article defines a research agenda based on the findings of a 1-day workshop with participants actively involved in UKRI and EU funded projects for reusable packaging[1].

Findings identify 21 Consumer and Industry factors for future research, and highlight the need for design to improve consumer interaction and experience, to develop inclusive design solutions, and to help resolve issues related to hygiene and contamination. Additionally, the role of design as an enabler to increase transparency between stakeholders across the value chain was highlighted.

## Introduction

In Europe, nearly 80 million tonnes of packaging is placed on the market annually (Eurostat, 2019). 80% of packaging waste is recovered, however, only 40% is recycled (ibid). Recently, there has been an interest in developing reusable packaging systems (RPS) to address the environmental and economic impacts of single-use packaging wastage and the loss of value within the system. Reusable packaging is “packaging which has been conceived, designed and marketed to carry out multiple trips in its lifetime by being refilled or reused for the same purpose for which it was conceived” (EU Directive 94/62).

Plastics are a valuable commodity, with their energy efficiency and material usage outweighing “green” alternatives such as aluminium and glass (Helmche et al., 2022). RPS can help mitigate the usage of single-use plastics (SUP), by keeping the plastic components in the system for longer through the return, refill, or repurposing of existing containers (Greenwood et al., 2021). However, RPS create complex socio-economic and environmental trade-offs (Meyhoff Fry et al., 2010; Stefanini et al., 2020), with the viability of reuse systems dependant on various factors, such as cycle rates, profitability, and consumer acceptance (Long et al., 2022; Vezzoli et al., 2015).

With pressure from policy makers, some UK retailers have been trialling different types of RPS for a range of products including food, beauty, and homecare products (Tesco, 2022). However, there is limited understanding about how to scale-up and mainstream RPS. Scale-up has been hindered by barriers such as user adoption, supply chain reconfiguration, and perceived economic costs. Design, we

propose, could play an important role in the successful implementation and scale-up of RPS.

## Methodology

Workshop participants - the authors of this paper – include nine academics and professionals actively involved in UKRI and EU-funded projects focused on reusable packaging1. Two main objectives were identified for the workshop: 1) to explore the key challenges for scaling up RPS; and 2) to collaboratively identify and prioritise key design research questions. These formed the basis of the research agenda defined within this paper.

For the first activity, eight categories based on the findings from a round table discussion held as part of an All-Party Parliamentary Sustainable Resource Group Inquiry were presented (Table 1). Insights gathered were discussed, with initial coding established to confirm category placement.

| Category | Example Definition |
|---|---|
| (i) Collaboration | Defining standardised practices through stakeholder collaboration to mainstream RPS. |
| (ii) Environmental impact | Calculating required cycle rates for reusable containers to be environmentally beneficial (break-even). |
| (iii) Labelling | Communicating with the consumer to increase engagement. |
| (iv) Consumer behaviours | Understanding consumer motivations for changing behaviours, and how motivations can be morphed into actions. |
| (v) Accessibility | Exploring how social equity can be embedded within RPS, how RPS can be desirable, available, and affordable for various demographics. |
| (vi) Logistics and supply chains | Current linear supply chains are optimised to reduce costs, reverse supply chains may increase costs deterring uptake. |
| (vii) Hygiene | Touchpoint cleanliness can impact a consumer perception of RPS. |
| (viii) Policy | The role of policies, legislation, and tax incentives for industry uptake. |

**Table 1. Categories Identified within the All-parliamentary Resources Group (Corsini & Ceschin, 2022).**

For the second activity, participants identified gaps in current research, mapping these to generate research questions. Questions were prioritised by each individual and then discussed within the group to justify their placement.

**Figure 1. Workshop participants at Brunel University London (June 2023) – discussion activity.**

The session was recorded and transcribed, with additional questions raised during the session added to the dataset. Participants verified findings and themes discussed until a consensus was met. Themes were divided between those relating to consumer and industry perspectives. For consistency, workshop themes were analysed and systematically reviewed against reuse factors and sub-factors presented by Bradley & Corsini (2023).

## Findings

In part one, participants identified themes relating to their current knowledge and future research (Figure 2, Figure 3). From this, themes have been translated to be consistent with the factors identified by Bradley & Corsini (2023) (Table 2). Highlights include:

- Lack of research to determine consumer demographics, and how this can influence the effective uptake of RPS.
- Consumer motivation is crucial for the adoption of RPS, but how this is achieved is still to be explored.
- Reuse needs to consider hygienic practices, with consumers concerned with content quality and the industry is concerned about liability issues.
- Standardisation will help to mainstream RPS, but establishing consistent standards and packaging is difficult to achieve without

government driven legislation and policy change.
- Multi-disciplinary stakeholders should be included within future RPS design.

| | Factor (Bradley & Corsini (2023)) | Workshop Theme |
|---|---|---|
| Economic | Material, infrastructure, and operational costs | Industry Investment |
| | Labour | Training |
| | Customer retention | Incentives |
| | Logistics | Supply chain |

**Table 2. Future research areas: Example mapping Industry Workshop Themes for future research to Bradley & Corsini (2023) – refer to Appendix A for all consumer and industry codes (Tables 1a &1b).**

In part two of the workshop, research questions were identified, with codes expanded based on the research question category. This led to 10 consumer factors and 17 industry factors (Figure 4, Figure 5).

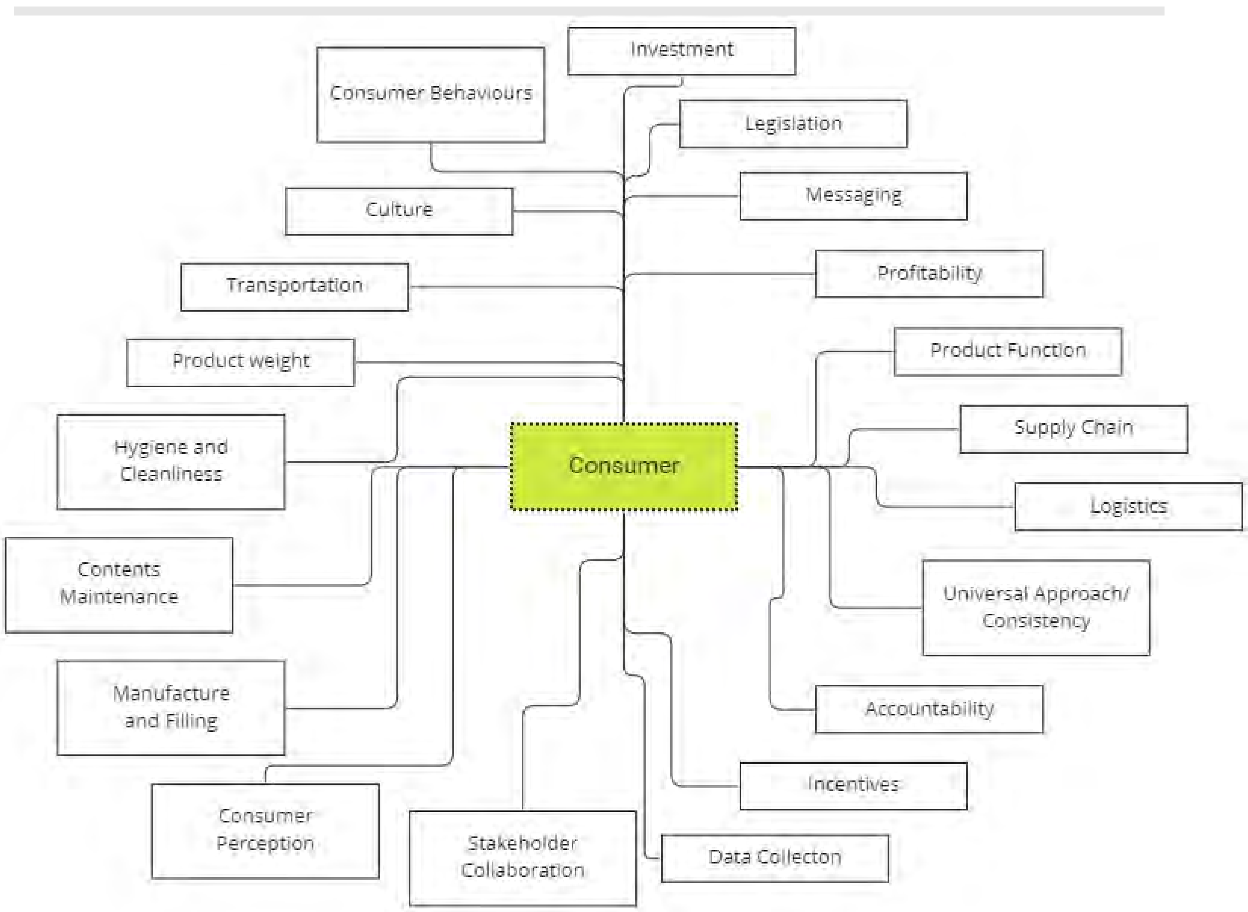

**Figure 2. Consumer themes identified within the workshop.**

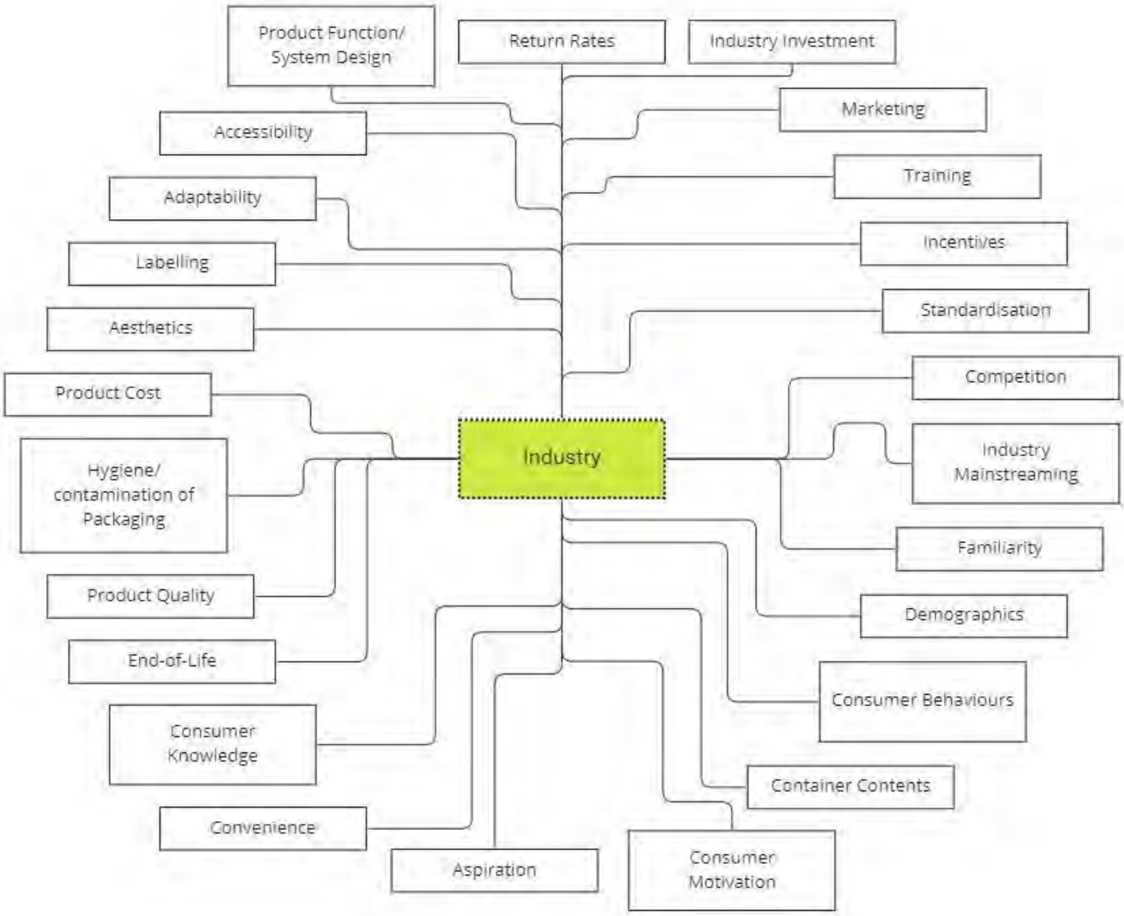

**Figure 3. Industry themes identified within the workshop.**

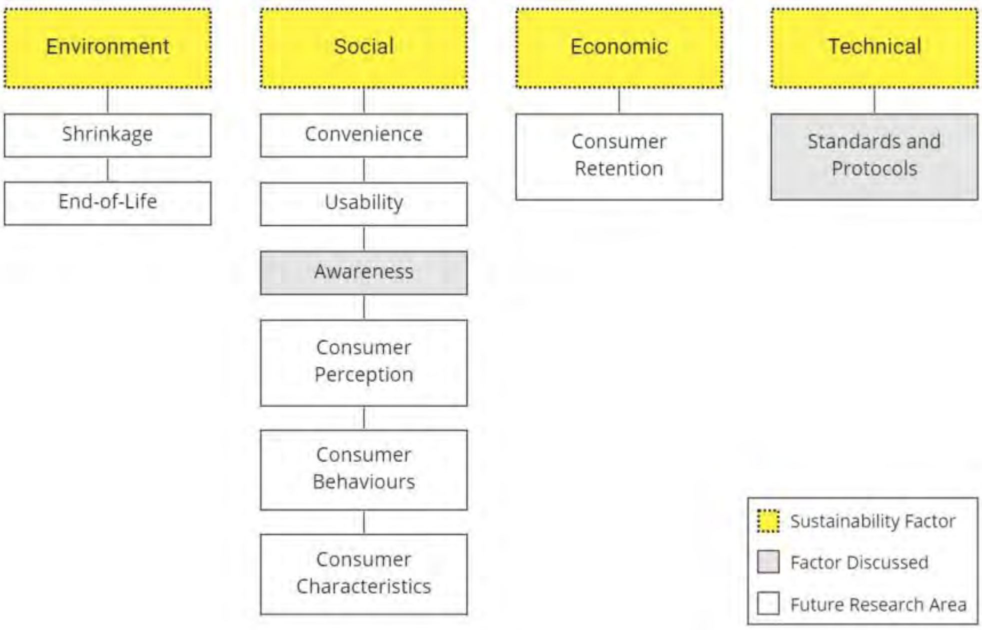

**Figure 4. Mapped Consumer factors for future research.**

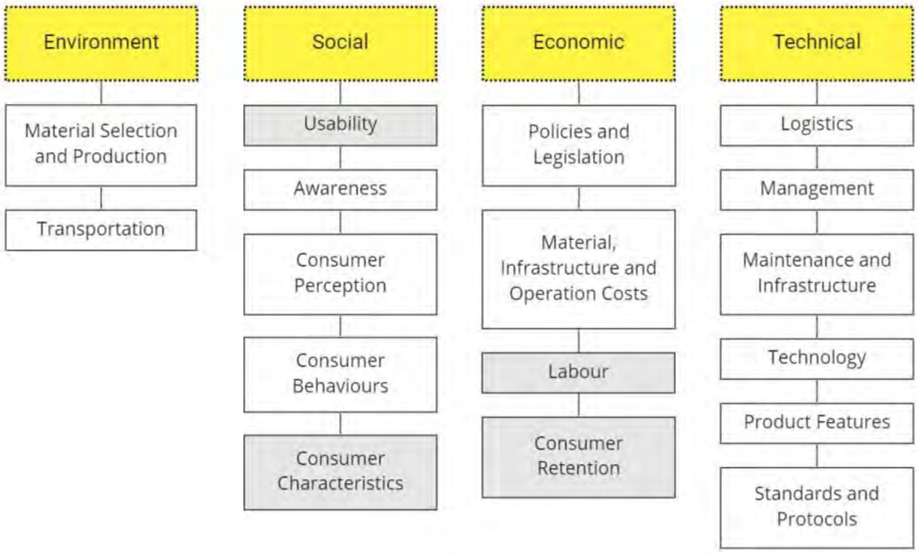

**Figure 5. Mapped Industry factors for future research.**

## Research Agenda

See Appendix B, Table 2a & 2b for all research questions identified.

### *Consumer Perspective*

Within this section, 8 factors for future research from a consumer perspective are discussed (Figure 4).

Environmental Factors

*Shrinkage.*

Shrinkage is the reduction of container quantity throughout the value chain, typically through container loss, damage, and misuse. For reuse to outperform SUP, minimum cycle rates are required. Return rates are dependent on the service provided and product category. Due to poor return rates providers can be quick to abandon reuse schemes without refining practices. Consumer convenience, behaviour change, and return incentives should be explored to ensure shrinkage is minimised and cycle rates are optimised.

| **Example research questions** |
|---|
| • How can the design of RPS prevent misuse, and clarify the products intended use? <br> • How can the RPS be designed to include the alternative product uses to remove the possibility of shrinkage through misuse? |

**Table 3. Design Research questions related to Shrinkage.**

*End-of-Life (EOL)*

Consumers can be confused by mixed messaging and limited knowledge of disposal practices (Clark et al. 2022). This coupled with inconsistent recycling infrastructure, dampens the consumers' willingness to engage in sustainable disposal practices. Whilst reuse is seen as a valid aid to reduce the reliance on recycling, consumer behaviour changes and education on the intended disposal route is required to ensure reusables remain in the closed loop. At EOL, reusables should be re-entered into the closed loop, maximising circularity, and lowering overall contribution. Design research should define how to maximise returns and maintain system circularity.

| **Example research questions** |
|---|
| • How can reusable packaging be designed for the last use and End-of-Life? |

**Table 4. Design Research questions related to End-of-Life.**

Social Factors

*Convenience.*

Reuse systems are currently designed to be blended within current user habits to make consumers more open to reusable solutions through familiar practices. Systems should be readily available and widely accessible to meet consumer needs. Systems currently trialled, have adopted curb-side and at-home delivery models, as well as local shop pickups. Assigning drop-off locations can allow for consumers to return packaging with ease. It is suggested that poor convenience can increase single-use dependency.

| Example research questions |
|---|
| • How can RPS be designed to streamline consumer interactions, maximising convenience?<br>• How will alternative packaging systems impact user uptake?<br>• How can RPS incorporate diversity and inclusion? |

**Table 5. Design Research questions related to Convenience.**

*Usability.*
System usability focuses on the adaptability of the product (i.e. Coca-Cola multi-spray bottles) as well as product functionality. It is highlighted that packaging cannot be designed for the act of repurposing or the emotional attachment consumers may feel towards a product. However, you can integrate practices within the design phase to encourage alternative product purposes (Wilson et al. 2022). RPS research should determine the appropriate product features, functionality and use to ensure optimal uptake and cycle rate. Providing product value should increase consumer uptake.

| Example research questions |
|---|
| • How can user motivations be influenced through the design of RPS?<br>• How can RPS be designed to improve the users return experience?<br>• How can the intended product use be communicated to consumers effectively?<br>• How can RPS design encourage consumer engagement? |

**Table 6. Design Research questions related to Usability.**

*Consumer Perception.*
The product aesthetics, quality, and cost can influence a consumer's decision to engage with RPS. Additionally, integrating historical design influences may increase user uptake by presenting the perception of reliability and durability. Meanwhile consumers can associate RPS with inferior cleanliness/ contamination hindering product uptake. Packaging contents affect consumer perception with consumers more likely to reuse packaging for fruit and vegetables, dry goods, and household goods than meat and alcohol (Shipton and Fisher, 2016). Both packaging product hygiene and the hygiene of the refill station should be considered when designing RPS.

The effect price has on perception is yet to be justified. However, it is theorised that reducing the price-gap between single-use and reusables can be perceived as better value-for-money, but may increase disposal rates due to the resultant perception of lower value. Designing the user experience to be enjoyable may increase RPS by establishing status. RPS can be designed to exude luxury, integrating human-led services to present exclusivity, and increasing product longevity through maintenance/ servicing.

| Example research questions |
|---|
| • How can design change the social perception of single-use product consumption?<br>• How does design influence consumer reuse/ behaviours?<br>• How can reusable packaging be designed to be aspirational?<br>• How can the effective design of a product service system influence the consumer uptake?<br>• How can RPS be designed to be enjoyable?<br>• How can design challenge consumers hygiene and contamination concerns?<br>• How can RPS be designed to evoke transparency on cleaning practices? |

**Table 7. Design Research questions related to Consumer Perception.**

*Consumer Behaviours.*
Understanding consumer behaviours is required to streamline and integrate RPS without negative implications. Short-term reuse trials have not accurately examined long-term reuse habits. Aligning system functionality with familiar practices and motivations can improve engagement and behaviour (Clark, 2020), however, consumers should be held accountable for failing to fulfil tasks or meet cycle-rates. To tackle this issue and to define optimal RPS, participants suggest the inclusion of psychology or sociology researchers within the system design to study attitudes, habits and behaviours of prolonged system interaction.

| **Example research questions** |
|---|
| • How can the design of RPS increase consumer engagement?<br>• How can design be informed by theories of behaviours?<br>• How can design ensure instore refill systems are convenient for all users?<br>• How can design research help to define the unintended consequences of reusable packaging within the different product categories? |

**Table 8. Design Research questions related to Consumer Behaviours.**

*Consumer Characteristics.*

Personalisation and technical attributes can increase consumer demand, whilst pro-environmental behaviours appear to be effective at encouraging consumers to engage. Personalisation increases the emotional attachment, desirability, and individuality of the product (e.g., Tate Modern and Chilly water bottle collaboration). Whilst this technique has been explored to change consumer behaviours, research is lacking to solidify the assumption. Varying cultures can also aid and hinder reuse integration. Cultural differences can change industry behaviour, whilst country density may also affect uptake (e.g., America may have more landfill space, therefore will not prioritise reuse strategies due to the limited visible plastic pollution). Current systems are targeted towards middle-class early adopters, as RPS demographics (e.g., sex, age, education, societal influences) are poorly explored. Defining the target audience assists marketing and sales, whilst understanding the cultural barriers streamlines the integration and increases acceptance rates of RPS.

| **Example research questions** |
|---|
| • How can design research help to identify the target audience for RPS?<br>• How can design research help to specify geographic trends in relation to RPS uptake?<br>• How can design research help to define the challenges of RPS uptake for consumers from varied demographics?<br>• How can RPS be designed to take into consideration the various demographic barriers to reuse uptake?<br>• How can RPS respect cultural beliefs to increase uptake?<br>• How can RPS be designed to facilitate inclusivity and diversity?<br>• How can packaging be designed to include consumers with visual impairments? |

**Table 9. Design Research questions related to Consumer Characteristics.**

Economic Factors

*Consumer Retention.*

Maintaining consumer engagement is critical to RPS success. There is limited research on the impact of incentives, however some argue that they can increase consumer uptake, but may also lower product value and result in increased disposal habits. 'Starter packs' are a good example. Consumers may find the reduced price for a refill and product better value than refills-only due to the lower costs, resulting in a greater consumption and lower cycle rate. Loyalty points may be effective, reducing the retailer's investment costs whilst also providing an immediate tangible reward to increase user return. Research should aim to identify drivers for reuse uptake, and how consumer engagement can be maintained.

| **Example research questions** |
|---|
| • How can return points be designed for convenience? i.e interactions and location |

**Table 10. Design Research questions related to Consumer Retention.**

## *Industry Perspective*

Within this section, we discuss 13 factors for future research from an industry perspective (Figure 5).

Environmental Factors

*Material Selection and Production.*

Packaging design attributes can help to reduce the environmental impact of RPS during the production and transportation phase of reusable packaging. Light weighting products can result in lower carbon contributions and energy consumption. Material selection and product features should be incorporated within the design of RPS.

| **Example research questions** |
|---|
| • How can the design of packaging reduce the environmental impact of increased product/material weight? |

**Table 11. Design Research questions related to Material Selection and Production.**

*Transportation.*

During transportation and use, stakeholders want to ensure the contents of the packaging are secure, and the quality and safety is maintained. Damage during transportation ultimately impacts product longevity, cycle rates, and profit. Additionally, the distance travelled can determine system viability when compared to single-use alternatives. RPS research should aim to determine cost-effective asset management.

| **Example research questions** |
|---|
| • How can RPS be designed to evoke trust during product transit? |

**Table 12. Design Research questions related to Transportation.**

Social Factors

*Awareness.*

Inconsistent recycling infrastructure has shown to encourage poor disposal practices. OPRL aims to standardise messaging through introducing binary labelling (OPRL,2021). Simple messaging should be incorporated within RPS to reduce product misuse and loss. Intuitive system messaging may be achieved through the inclusion of educators (e.g., teachers and storytellers) within the system design. The marketing of reusables should be evident within stores to promote consumer system awareness. System benefits should be reiterated to consumers, based on their values.

| **Example research questions** |
|---|
| • How can design help to separate packaging from marketing? |

**Table 13. Design Research questions related to Awareness.**

*Consumer Perception.*

RPS can have the perception of lower content quality or poor taste due to the associated contamination and alternative materials used. For example, reusable coffee cups can alter the coffee taste when suds remain after cleaning. To change consumer perception, visibility of cleaning practices can evoke comfort when using reusables (e.g., dishwasher to clean pint glasses at public houses). Consumers should interact with reusables on a regular basis to disassociate container cleanliness and contamination. Design research should identify how RPS can evoke and maintain hygiene.

| **Example research questions** |
|---|
| • How can design change industry perception of packaging as a product to a system? |
| • How can design improve the instore reuse retail experience? |
| • How can reusable products be designed to integrate within the entire service chain? |
| • How can design aid the conveyance of reliability and cleanliness? |

**Table 14. Design Research questions related to Consumer Perception.**

*Consumer Behaviours.*

It can be argued that by limiting the consumers choice, consumers are forced to change their behaviour. However, brand loyalty may present difficulties in changing consumer preference. For this to be successful, all competitors should agree to a standard practice (e.g., a ban on single-use bags).

| **Example research questions** |
|---|
| • How can the design of a system make reuse the default option? |
| • How can design research help to identify the product categories that are most suitable for reuse? |
| • How can design research help to define the unintended consequences of reusable packaging within the different product categories? |

**Table 15. Design Research questions related to Consumer Behaviours.**

Economic Factors

*Policies and Legislation.*

Consumer motivations are not enough to change industry practices, with companies able to avoid accountability through generalising commitments. Tax, policy, and legislation can enforce targets and penalties to hold companies accountable for negative practices (e.g., Extended Producer Responsibility). The evolving nature of legislation presents the risk of re-classifying packaging as products. Resultant tax implications may lead to limited industry adoption. For RPS management to be streamlined, standardisation of international regulations is required, and further funding opportunities provided.

| **Example research questions** |
|---|
| • Who is responsible for standardising RP? |
| • How can a shared standard be achieved that facilitates reuse? |

**Table 16. Design Research questions related to Policies and Legislation.**

*Material, Infrastructure, and Operational Costs.*

Associated system costs can deter producer, retailer, and consumer investment. Businesses pivoting to new structures may experience impacted sales and fail to meet management targets during the early stages of adoption.

Unless support for reusables is established at a management level, companies may revert to linear systems to reduce the risk of low economic return (Clark et al. 2020). Reassurance of the value RPS can provide, as well as validate profitability needs to be given to the company. Defining responsibility within the system is also fundamental, especially when considering the repair, manufacture, and management of assets to meet cycle rates.

| Example research questions |
| --- |
| • How can RPS be designed to ensure profitability?<br>• How can RPS be designed to reduce the risk of investment? |

**Table 17. Design Research questions related to Material Infrastructure and Operational Costs.**

Technical Factors

*Logistics.*

Shifting from linear to circular systems can be difficult for industries who have optimised their supply chain processes. Industries want to be innovative, but at the same time are hesitant to take new practices to market. Some wait for leading industries to first take the risk and implement new strategies to reduce the economic risk. Companies need to share data collected for mainstreaming of RPS to be achievable, but currently, there is no economic incentive for industries to do so. This may be due to the limited relationships between current stakeholders, and the competitive nature of emerging markets. System design should include multi-disciplinary stakeholders, not least, business designers, system architects, manufactures and engineers.

| Example research questions |
| --- |
| • How can design research help to define the steps of transitioning from single-use to RPS?<br>• How can design research help to define the new actors within RPS supply chains?<br>• How can RPS be optimised to streamline the flow of reusable packaging/ containers?<br>• How can design research help to define a standardised criterion for reusable packaging across industries?<br>• How can the design of primary reuse systems be influenced by secondary/ tertiary packaging systems?<br>• How can RPS design be universal for multiple FMCG product categories?<br>• How would design build a better infrastructure where all stakeholders are making good business?<br>• What does it mean for companies to have standardised packaging that is interchanged in an open system? |

**Table 18. Design Research questions related to Logistics.**

*Management.*

Defining the interlinking relationships and system architecture is vital to creating an optimised system. To achieve a universal design, multi-disciplinary stakeholders should be included in the research, design and development phases. These can include: retailers, manufacturers, packaging technologists, engineers, customers, business designers, psychologists, sociologists etc.

| Example research questions |
| --- |
| • How can design research aid the upskilling of packaging designers transitioning to reuse?<br>• How can design research utilise stakeholder communication and connections to collect data and convince businesses to adopt refined business models?<br>• How can design research influence and initiate collaboration between stakeholders? i.e consumers, retailers and producers<br>• How can RPS be designed to foster collaboration across the value chain?<br>• How can RPS design motivate other stakeholders to collaborate within the management and design of the system?<br>• How can the design of RPS help to identify the responsible stakeholders and their associated roles/ responsibilities? |

**Table 19. Design Research questions related to Management.**

*Maintenance and Infrastructure.*

Product cycle rates depend on product type, refurbish and refill rates. Determining the potential liability is necessary to optimise container flow and reduce shrinkage. Retailers are focused on sales rather than asset management and hygiene. Third-party logistics can provide cleaning, repair, and asset management to out-source liability to qualified stakeholders. Further research is required to determine effective contents management within the supply chain to maintain product quality and hygiene.

| Example research questions |
|---|
| • How can design research help to define liability within the system?<br>• How can design research identify the challenges providers, retailers, and suppliers of RPS face? |

**Table 20. Design Research questions related to Maintenance and Infrastructure.**

*Technology.*
Insights based on data collection can incentivize industries to invest in RPS. Tracking and monitoring consumer usage could be deemed invasive, leading to reduced consumer uptake. Data should be ethically and transparently collected with justification provided to enhance consumer acceptance.

| Example research questions |
|---|
| • How can design research establish effective data collection practices throughout the consumer journey?<br>• How can design research assist the collection of consumer data to incentivise circular business models? |

**Table 21. Design Research questions related to Technology.**

*Product Features.*
Industries are currently emphasizing the importance of packaging itself, however, the product contents should be the Unique Selling Point (USP). However, standardisation of packaging design may result in difficulty differentiating brands as actual product feature USP may be negligible (Fleet & Ankudinova, 2023). Refill trials and research are needed to identify how brand identity can be portrayed through standardised packaging.

| Example research questions |
|---|
| • How can design assist the brand unique selling point vs standardisation challenge? |

**Table 22. Design Research questions related to Product Features.**

*Standards and Protocols.*
Standardisation of hygiene practices should reduce contamination and reassure consumers (Fleet & Ankudinova, 2023; Nahar et al., 2023). To ensure consistency, reuse schemes need to be defined at a local and international level to accommodate for migrating communities. Mixed messaging and inconsistent practices can cause scepticism with consumers wanting to do the "right" thing, with poor disposal/return practices leading to increased supply chain issues.

| Example research questions |
|---|
| • How can RPS be designed to ensure packaging hygiene and cleanliness is maintained?<br>• How can design research aid the definition of effective green products? |

**Table 23. Design Research questions related to Standards and Protocols.**

## Conclusions

This study has defined a research agenda informed by two main objectives: (i) to explore the key challenges for scaling RPS, as well as current knowledge and limitations, and (ii) to collaboratively identify key design research questions. This paper concludes how further research is required within 8 consumer focused areas, and 13 industry areas. Some salient foci for future research include: (i) Stakeholder Collaboration, (ii) Data Collection, (iii) Consumer Behaviours, and (iv) Consumer Experience. Demographics should be measured to understand who the intended consumer should be, and how systems should be designed to include cultural aspects, beliefs, knowledge, and attitudes. To achieve RPS success, consumer attitudes, knowledge and behaviours need to be better understood and utilised within the design of RPS. Exploring these areas through future research can help to mainstream future reuse systems.

# From colouring excels by hand to using advanced algorithms: Digital technologies as enablers of the circular economy

**Christian Bücker[(a)], Julia Pantel[(b)], Martin Geissdoerfer [(c)], Mukesh Kumar [(a)]**
a) Institute for Manufacturing, Department of Engineering, University of Cambridge, Cambridge, UK
b) Institute for Technology and Innovation Management, Hamburg University of Technology, Hamburg, Germany
c) Circular Economy Centre, Judge Business School, University of Cambridge, Cambridge, UK

**Keywords**: Circular economy; Digital technologies; Customer behaviour; Circular business model innovation; Multiple-case study.

**Abstract**: The circular economy has received significant attention from academia and industry. However, the broad implementation of circular business models is still pending. One reason is the lack of customer acceptance, representing a critical barrier to circularity. Digital technologies garner increased recognition as enablers of circular economy implementation. This paper examines the role of digital technologies in achieving customer acceptance for consumer-facing companies in the circular economy. To gain practical insights from industry, we employ an empirical research approach based on semi-structured interviews, consisting of eight expert interviews to map the field, thirteen multiple-case study interviews to analyse six case companies, and secondary data to triangulate the information. As a result, we develop a thematic structure for (a) factors of customer acceptance of circular business models, (b) practices companies can deploy to address these factors, (c) digital technologies to facilitate these processes, and (d) real-world use cases in which all these components interact in unison. Our findings highlight the striking differences between incumbents and start-ups in their approaches', key challenges, and enablers. In particular, we identify supply chain collaboration as central for companies in the circular economy to achieve economies of scale and of scope in an effort to accelerate the transition towards the circular economy.

## Introduction

The European Union is undergoing two major transitions, one directed at sustainability, the other at uncovering the potential of digital technologies (European Commission, 2022). The circular economy is considered a stepping stone for economies to operationalise sustainable development (Ghisellini et al., 2016). However, the lack of customer acceptance towards circular business models is a key barrier to the transition towards the circular economy (Kirchherr et al., 2018). While digital technologies are recognised as enablers of the circular economy, companies' utilisation of digital technologies to achieve customer acceptance for their circular business models is underexplored (Ranta et al., 2021; Toth-Peter et al., 2023).

This paper will address this research gap, building on the literature from the circular economy, customer behaviour, and digital technologies.

## Theoretical background

### *Circular economy*

The circular economy is "an industrial system that is restorative or regenerative by intention and design" (Ellen MacArthur Foundation, 2013, p. 14). It aims to transition away from the linear economy's predominant take-make-dispose approach, which is environmentally, economically, and socially unsustainable (Ghisellini et al., 2016; Lieder et al., 2017). It does so "through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling" (Geissdoerfer et al., 2017, p. 6).

Implementing the circular economy requires fundamental product, service, and customer relations transformation (Lewandowski, 2016) and circular business model innovation (Linder & Williander, 2017). Companies can use circular business models to propose, create, and deliver value to their customers (Bocken et al., 2016). However, to capture value, companies are dependent on their customers' acceptance, as customers are the final decision maker (Kirchherr et al., 2017).

### *Customer behaviour*

There is consensus that "consumer behaviour is one of the key levers for enabling the transition to a circular economy" (European Environment Agency, 2019, p. 25). However, customer acceptance was identified as one of the key barriers to the implementation of the circular economy (Kirchherr et al., 2018). Hence, researchers are urged to "identifying drivers, barriers and practices" to explore its implementation (Govindan & Hasanagic, 2018, p. 307). We define drivers and barriers as factors that affect customer acceptance either positively or negatively and practices as methods companies can deploy to foster customer acceptance by altering the customer perception of such factors.

### *Digital technologies*

Digital technologies, such as artificial intelligence, big data analytics, blockchain, internet of things, and mobile technologies, have been identified as critical enablers of circular business model innovation to address customer behaviour (European Environment Agency, 2019; Ranta et al., 2021). Yet, "research on the implementation of digital technologies and related business model innovations for establishing circular economy within firms remains conceptual and lacks empirical evidence", particularly for "consumer-facing business models, where consumer acceptance of circular economy business models is of concern" (Ranta et al., 2021, pp. 1, 10).

### *Research question*

The sections above identified the relevance of the three intersecting fields, circular economy, customer behaviour, and digital technologies, and revealed a gap in the literature. To address this gap, we propose to answer the following research question:

*How do consumer-facing retailers/ manufacturers of consumer durables in the circular economy utilise digital technologies to achieve customer acceptance for their circular business models?*

## Methodology

We employed a three-part research approach consisting of expert interviews, multiple-case studies, and triangulation with secondary data.

First, we conducted eight qualitative semi-structured problem-centred expert interviews (Döringer, 2021), as an established approach in technology forecasting (Wang et al., 2019). Given the limited empirical research on this topic, we utilised the experts to map the field, understand causal relationships of the system, for their anticipatory sensemaking, and ability to identify necessary actions (Rudolph et al., 2009; Wang et al., 2019). To generate rich and diverse data, we chose experts from academia, consulting, and industry (Table 1), as done in similar approaches (Fabbe-Costes et al., 2014; Hofmann & zu Knyphausen-Aufseß, 2022).

| **Data input** | **Inter-view code** | **Time (min)** | **Role** |
|---|---|---|---|
| **CaseCo** | | | |
| Furniture Inc | i1 | 65 | Circular business designer sustainable Innovation |
| | i2 | 45 | Product development engineer |
| Electric Inc | i3 | 50 | Sustainability director/head of CE |
| | i4 | 85 | Director ownership sales & services |
| Textile Inc | i5 | 55 | Supply chain manager |
| | i6 | 80 | Sourcing and development manager |
| Electric Start | i7 | 40 | Founder & CEO |
| | i8 | 55 | Director of strategy & new business |
| | i9 | 50 | Head of product |
| Furniture Start | i10 | 70 | Co-founder & managing director |
| | i11 | 70 | Co-founder |
| Textile Start | i12 | 70 | Innovation business strategy specialist |
| | i13 | 45 | ESG specialist |
| **Expert interviews** | | | |
| Consumer electronics | n/a | 90 | Head of Sustainability; Founder; PhD researcher CE Innovation |
| CE Fintech | n/a | 60 | Head of sustainability; CE researcher & lecturer |

| | | | |
|---|---|---|---|
| Furniture | n/a | 55 | Managing director |
| Textile | n/a | 55 | Product manager |
| Consulting (CE, consumer goods) | n/a | 60 | Associate partner |
| Think Tank (CE) | n/a | 60 | Director |
| Consulting (dig. tech) | n/a | 45 | Senior expert |
| Academia (CE) | n/a | 60 | Assistant professor |
| **Secondary data** | | | |
| Publicly available interviews, press releases, public letters, corporate website | | | |

**Table 1. Overview of data sources.**

Second, building on the knowledge derived from the expert interviews, we chose an exploratory multiple-case study approach based on semi-structured interviews (Table 2). This approach accounts for the novelty of the investigated phenomenon and is suitable to address 'how' questions, as posed above (Yin, 2018). Our case selection employed theoretical sampling principles (Eisenhardt & Graebner, 2007) and followed these selection criteria: (1) Through the use of maximum variation criteria (Patton, 2001), we chose cases from different industries (consumer electronics, furniture, fashion/textiles) and company sizes (small to large). (2) We chose cases with differing maturity levels (incumbents vs. start-ups) and business models types (product ownership vs. product-as-a-service) to ensure a diverse spectrum of organisational approaches. (3) We selected companies that were engaged in the circular economy for several years, running mature and profitable businesses, and deployed circular business models that gained customer acceptance. Yet, we specifically did not preselect cases for their utilisation of digital technologies to allow for an unbiased industry assessment.

Third, we reviewed case-related secondary sources of information in the form of publicly-available company interviews, press releases, and corporate websites to enrich the body of data for triangulation and to avoid post-hoc rationalisation (Yin, 2018).

| CaseCo | Industry | Maturity type | Employees | Country | Business model type[1] | Circular economy offer |
|---|---|---|---|---|---|---|
| FurnitureInc | Furniture | Incumbent | >100,000 | SE | PO | Used products, products with recycled/recyclable content, take-back system |
| ElectricInc | Consumer electronics | Incumbent | >50,000 | SE | PO, PaaS | Products with recycled/recyclable content, rental/subscription option, repair service s |
| TextileInc | Fashion/ Textiles | Incumbent | <500 | FI | PO | Products with recycled/recyclable content, products with cradle-to-cradle certification, take-back system |
| ElectricStart | Consumer electronics | Start-up | <500 | AU | PO | Refurbished/used products, products with , recycled/recyclable content sold via platform |
| FurnitureStart | Furniture | Start-up | <50 | DE | PO | Refurbished products, refurbishing service |
| TextileStart | Fashion/ Textiles | Start-up | <500 | CH | PO, PaaS | Products with recyclable/bio-based content, subscription option with take-back system |

**Table 2. Overview of case companies.**

[1] PO: product ownership, PaaS: product-as-a-service

## Results

We discovered a common pattern that conceptualises the process of achieving customer acceptance for circular business models, consisting of three elements.

First, companies identify influencing factors, that determine customer behaviour. These are either drivers or barriers of acceptance. Second, companies innovate their circular business models to account for their customers' behaviour using practices. Practices are methods that companies can deploy to foster customer acceptance by altering the customers' perception of previously identified factors. Third, companies use technological enablers, such as digital technologies, facilitating the above processes.

The following sections display the identified constructs individually and interrelatedly, in the form of use cases.

### *Factors of customer acceptance*

Customer preferences are diverse. The interviewees provided a total of 24 different factors influencing customer acceptance (Figure 1). While sustainability was mentioned most often, it is not considered to be the most important in customer decision making, but rather a positive add-on as long as key decision factors are met. These are price, as the most important factor, followed by quality, convenience, and trust.

### *Practices of customer acceptance*

The case companies show an even greater diversity of how they react on their customers' acceptance factors, naming 34 different practices (Figure 2). These practices span across the organisations' corporate functions, from upstream activities, enhancing supply chain transparency, to downstream, offering repair services after sales.

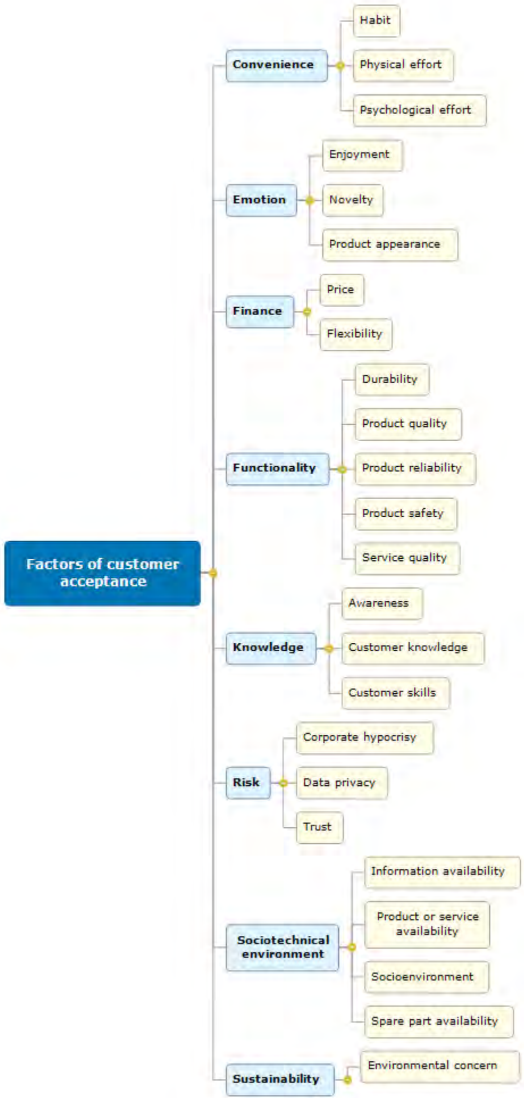

**Figure 1. Factors of customer acceptance.**

### *Digital technologies*

The interviewees identified 17 digital technologies in their organisations related to customer acceptance of circular business models. While three of them were still in the planning phase (i.e., blockchain, digital product passport, digital twins) and one in the testing/piloting phase (3D printing), the remainder is in use in at least one of the case organisations. The technologies' applications span from the production layer to the service layer. However, most technologies are used for cognition purposes, to derive insights from the data gathered across the supply chain.

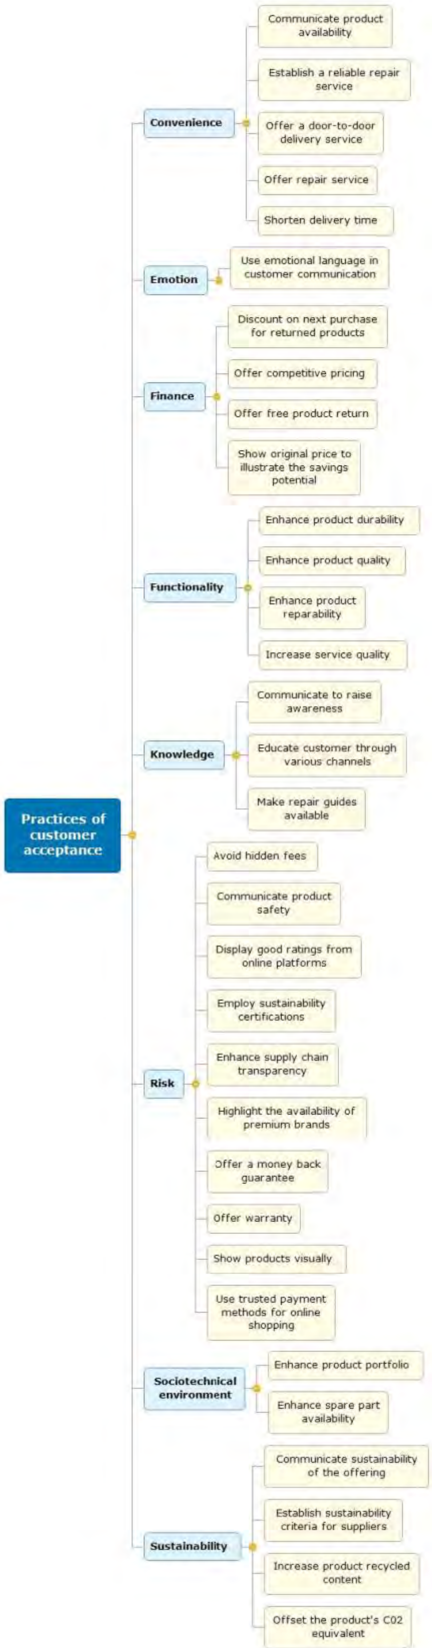

**Figure 2. Practices of customer acceptance.**

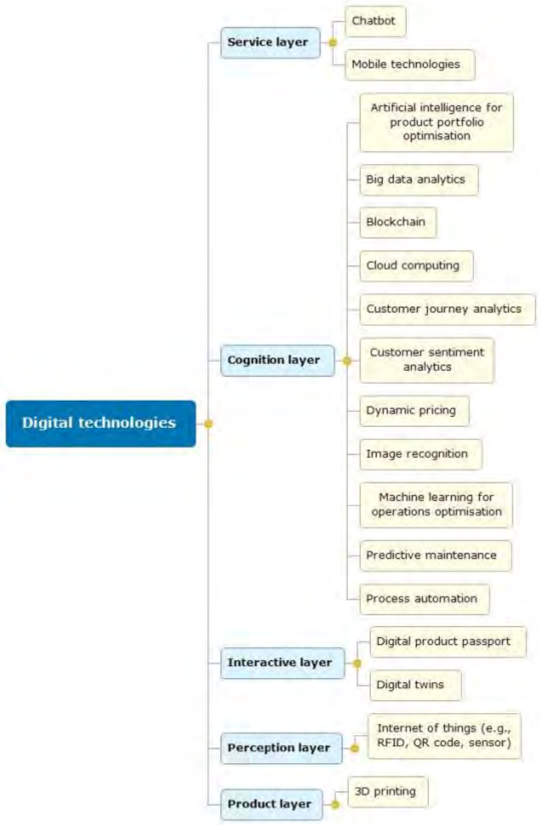

**Figure 3. Digital technologies.**

## Use cases

The previous sections highlighted the identified factors, practices, and digital technologies in isolation. However, companies use their knowledge and capabilities regarding these concepts in combination to achieve customer acceptance, identifying factors, developing practices, and utilising digital technologies.

### *ElectricInc: Enhanced service quality through predictive maintenance*

As a premium manufacturer, ElectricInc's customers' expect high product reliability and service quality (Figure 4). To establish a reliable repair service[2], ElectricInc has installed internet of things-related technology that collects, transmits, and analyses large quantities of customer usage data. Through the use of predictive maintenance algorithms, the customer data is aggregated to derive probabilities for regional repair service needs. This allows ElectricInc to prepare their service capacities accordingly, enhancing the service quality. Additionally, service personnel is trained to educate their customers on optimal device usage, improving product reliability and sustainable behaviours.

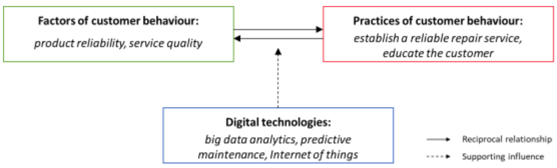

**Figure 4. ElectricInc: Predictive maintenance.**

### *FurnitureStart: Enhanced information availability through process automation*

While FurnitureStart uses its own website as its central sales channel, it also uses a range of other sales platforms, including Ebay, Amazon, and Facebook, to enhance product availability. Refurbished products face increased customer scrutiny (i.e., trust), especially when sold online and via third party websites. Therefore, customers desire reliable product information, including photos and detailed product descriptions, for peace of mind (Figure 5). However, uploading such data manually across multiple websites is unfavourable for FurnitureStart and its customers, as manual processing is slow, costly, inaccurate at times, and causes conflicts [3]. To overcome this challenge, FurnitureStart has developed proprietary software that processes the activation and deactivation of its products across all websites at the click of a bottom. Further, the process automation scripts ensure that product photos and descriptions are uploaded instantly to all websites, according to the individual websites' specific data requirements.

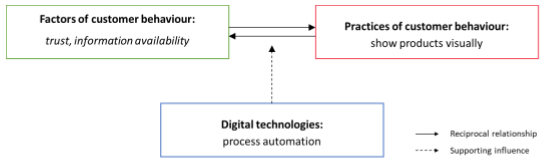

**Figure 5. FurnitureStart: Process automation.**

## Discussion

The previous section has shown how digital technologies are used to achieve customer acceptance for circular business models. Notably, the data shows differences on how companies approach this concept, especially between incumbents and start-ups, and which challenges and enablers they experience, which will be discussed below.

### Incumbents versus start-ups

Interviewees from both company types agree on the importance of understanding their customers' behaviour (i.e., factors), the development of methods to foster acceptance, and the importance of dynamic capabilities to identify those factors and develop, test, and implement practices in an agile way.

"First, we have to get to know the customer and learn what he wants. […] At the end of the day, it's about building some kind of relationship with consumers. […] For us, the consumer used to be kind of a black box." *- i4*

"It's good to try at least […]. And even if you plan a lot ahead, it will go differently than you think. So ... Don't be afraid to try." *- i2*

"You always have to ask yourself: What do things really bring? And test that. We're actually now moving away from doing the things where we just think that's great and are asking the customer more." *- i10*

A different picture emerges when assessing the role of digital technologies and the case companies' capabilities of using them. While respondents agree on the importance of digital technologies, they admit, especially incumbents, to lagging behind in their implementation.

[2] Since the pandemic, time spent in the home office has increased, rendering EletricInc's experience of service demand peaks, usually in the mornings and evenings, unreliable.

[3] when a product was bought on one website, but would still be available on others.

"That's a definite enabler, a thousand percent, because just the ability to work with the customer, to work with customer data, that's a huge asset that we didn't have before." - i4

"I wish I could brag with the coolest things in the world, right? But I have to say that here we have a lot to learn.." - i1

Incumbents face common challenges. These include slow decision making processes, unresolved areas of responsibilities for digital technologies-related innovation, and corporate functions working as silos, when cross-company collaboration is required. This leads to a situation in which even minor issues are cascaded to the senior management, which are overwhelmed with information overload, resulting in stagnation. One interviewee remarks that its 200 year old case company is still managing the basics of digital transformation, exacerbating the implementation of more advanced digital technologies.

"And the problem is when it's no one there in the company (to take the decision), it goes very high up in the company, which means the C-level or maybe the level just under them. [...] And I think that's why it takes such a long time for some (decisions) to be taken." - i1

"But this integrative concept, where you say it's all in one... that is, I think, a disadvantage of a global player with 50,000 employees worldwide, that we are unfortunately still very much stuck in silos." - i4

"It's all very, very manual work. It's always somebody filling the Excel or somebody is writing from the emails. So I think that's the main issue related to this topic, that everything is made very, very manually." - i5

Instead, start-ups tend to be more agile in their decision making and profit from their smaller size in collaborating on initiatives. Interviewees recognise the lack of capital to invest in digital technologies and their insufficient scale to distribute these costs as their main challenge.

"You can see that for start-ups that are exploring circularity, typically their business models and their products are simpler and more local. And being simpler and more local significantly benefits circularity in terms of how simply you can pitch what it is you're trying to do. But as soon as you have a big corporation that's trying to be global and trying to have multiple brands but still be built from, you know, just a few factories, the challenge is very different to a start-up perspective." - i3

"But if the question is, what's stopping us? Money. Well, you don't have an infinite amount of money, especially if you don't have an investor. We don't want to have an investor in it, so everything has to come from the cash flow or from the profit." - i10

## Challenges and enablers

There are a number of challenges raised by the respondents, that hamper the case companies to achieve customer acceptance, while they also refer to selected enablers. These challengers and enablers, mostly related to supply chain stakeholders and scale, are reported in Table 3.

| Challenge/ enabler | Topic | Description | Interview |
|---|---|---|---|
| Challenge | Legislation | Cost for example, as circular business models internalise externalities, such as unsustainable practices, at higher costs | i1, i3, i9 |
| | Infrastructure | Broadband for example, to allow business models depending on connectivity | i4 |
| | Experience & expertise | Lack the sustainability experience and experts in-house | i1, i5, |
| | Supply chain stakeholders | Suppliers are not ready to share information openly, for example on the blockchain | i4 |
| | | Manufacturers are unsupportive to provide spare parts to circular companies with repair- or refurbishment-business models | i9 |
| | | Service providers are lacking or do not deliver at the required quality levels, leaving circular companies to integrate services outside of their core expertise | i9 |
| | | Lack of knowledge exchange between supply chain partners | i6, i13 |
| | Scale | Circular companies or large corporations with small scale circular business models are yet lacking the scale for investments in capital intensive technologies to amortise | i6, i9 |
| Enabler | | Market places are important for small scale companies to find establish sales markets, without depending on building their own sales channel from the start | i10 |
| | | White label service suppliers, e.g., for reverse logistic services, allow smaller companies to pool transactions and increase economies of scale | i13 |

**Table 3. Challenges and enablers.**

## Conclusion

This research investigated customer behaviour in the transition to the circular economy and circular business model innovation to achieve customer acceptance. With the growing need for sustainable industrial practices and the proliferation of advanced digital technologies, we detect the emergence of a twin transition. To understand how companies leverage digital technologies to achieve customer acceptance, we conducted expert interviews, mapping the field, and conducted a multiple case study, determining concrete use cases, challenges, and enablers.

We conclude that digital technologies offer viable and diverse opportunities to supporting companies in achieving customer acceptance. These companies require dynamic capabilities to identify their customers' behaviour (i.e., factors), develop appropriate methods to cater to these behaviours (i.e., practices), and facilitate these methods through the use of technological enablers (i.e., digital technologies).

Further, we identified significant differences between incumbents and start-ups in their ability to utilise digital technologies. We highlighted challenges and enablers that are relevant across company maturity levels. Based on these findings, we recognise the the focal firm's challenging situation in building these capabilities. Hence, we emphasise the importance of supply chain partnerships, networks, and clusters to achieve economies and scope and of scale. We advise future research to address this topic from a network perspective with the participation of multiple supply chain stakeholders.

# Circular economy in EU critical value chains: The case of titanium metal in defence and civil aviation[1]

**Alejandro Buesa[(a)], Elena Garbarino[(b)], Hans Saveyn[(a)], Brian Baldassarre[(a)]**

(a) Joint Research Centre, European Commission
(b) European Defence Agency

**Keywords**: Critical raw materials; Supply chain; Strategic autonomy; Recycling; Titanium; Aerospace.

**Abstract**: Titanium metal is used in strategic applications including civil aircraft and defence systems. The EU, the material is entirely reliant on imports from third countries, resulting in notable supply risk. Recently, the invasion of Ukraine exacerbated concerns over potential disruptions. In this context, circular economy strategies can contribute to security of supply. The goal of this study is to provide insights into the circularity status quo and potential of the titanium metal supply chain, with a focus on the EU civil aviation and defence sectors. We use a mix of qualitative and quantitative research and modelling methods. The study is ongoing. In this paper, we present our preliminary results, namely: (1) a detailed diagram of the titanium metal supply chain including linear and circular processes, complemented with a selection of specific drivers and barriers to circularity in the EU; and (2) a quantitative estimation of titanium scrap trade flows, functional to develop future circularity scenarios assessed in terms of their economic and environmental impacts. The completion of this work will support the formulation of policy options and best industry practices to strengthen the circular economy and supply security in the EU.

## Introduction

Titanium metal is a valuable input for the industrial sector owing to its low weight, as well as mechanical properties and corrosion resistance. It finds applications in the chemical industry and medical equipment (Louvigné, 2021), but has also become fundamental for strategic technologies and critical value chains, two prominent examples being aircraft and defence systems (Blagoeva et al., 2019). The suitability of titanium parts in these applications has resulted in increased importance of this material in the aerospace and defence sectors. This trend is likely to continue in the near term as titanium is highly compatible with composite materials, which form an ever-increasing share in the composition of aerospace products.

In the European Union (EU) titanium metal is exposed to notable supply risk, as it is mostly imported from a limited number of third countries. Consequently, titanium recently entered the EU list of Critical Raw Materials (European Commission, 2020c; European Commission, 2023a). The invasion of Ukraine exacerbated concerns over potential disruptions, not least because Russia is a major supplier of titanium for the aerospace industry (European Commission, 2022). In this vein, ensuring the integrity of the supply chain for titanium is of paramount importance for the EU as it results in enhanced strategic autonomy, understood as the capacity of the EU to act autonomously without being dependent on other countries in strategically important policy areas (European Commission, 2020b).

One catalyst to strategic autonomy is implementing circular economy strategies: reducing primary material inputs by sharing, leasing, reusing and repairing products, as well as by recycling within the EU boundaries as far as possible (Ellen MacArthur Foundation, 2013; European Commission, 2020a). Such strategies allow mitigating import dependencies across sensitive supply chains such as those of renewable energy and aerospace and defence technologies (Mathieux et al., 2017).

However, applying circular economy strategies requires a deep understanding of the supply chain structure, as well as of existing economic,

[1] The views expressed in this manuscript are purely those of the authors and may not in any circumstances be regarded as stating an official position of the European Commission or the European Defence Agency.

regulatory, cultural or technological drivers and barriers (Baldassarre et al., 2022; Kirchherr et al., 2018). For titanium metal, some research exists on recycling (Takeda & Okabe, 2019) but circularity has not been investigated in depth, partly due to limited data availability and lack of disclosure by major actors in the industry (US Dept. of Commerce, 2016).

The objective of this paper is twofold. On the qualitative front, we aim to understand the structure of the titanium metal supply chain, identify relevant stakeholders and their interactions as well as integrate and systematise their insights on the status quo and potential of circularity and strategic autonomy. From a quantitative perspective, we envisage to map the material and economic flows with a focus on defence and civil aviation and secondary flows (i.e., scrap) to put circularity drivers, barriers, and their relevance in context.

## Methodology

Assessing the circular economy contribution to open strategic autonomy in critical value chains is a complex task. It requires combining well-established supply chain analysis procedures with novel techniques that allow to account for the specificities of each material or assembly. In addition, the economic and environmental aspects of circularity need to be factored into the analysis.

To this end, we adopt a hybrid multiple-step approach based on the combination of qualitative and quantitative research and modelling methods. We apply this method to the supply chain of titanium metal as a case study. The core idea is to provide enough leeway in the initial steps for the differential traits of each material to be well captured: progressing towards results, we work as systematically as possible to render the method easily scalable.

We start by performing a review of scientific and grey literature including industry reports and academic publications, which allows to depict a preliminary sketch of the value chain. Subsequently, we set up a stakeholder consultation covering all relevant stages of the value chain (Tier 1/2 suppliers, original equipment manufacturers-OEMs, end-of-life actors) as well as independent experts, industry associations, and academics. We interview 22 panellists (Figure 1); other qualitative methods such as surveys are conceivable and possibly complementary to our approach.

This step allows us to refine the value chain structure from the literature review, as well as to gain qualitative/quantitative insights that may, in an approximate fashion, fill data gaps derived from frequent confidentiality concerns by industry actors. Some examples thereof are:

- *Aircraft titanium content (airframe / engine)*
- *Market share of aerospace in production of titanium wrought products.*
- *Amount of scrap fed into manufacturing of primary material.*
- *Scrap recovered from end-of-life aircraft (old scrap) and suitability for remelting.*

Crucially, the outputs from stakeholder interviews will also translate into an overview of circularity drivers and barriers, as detailed in the Results section.

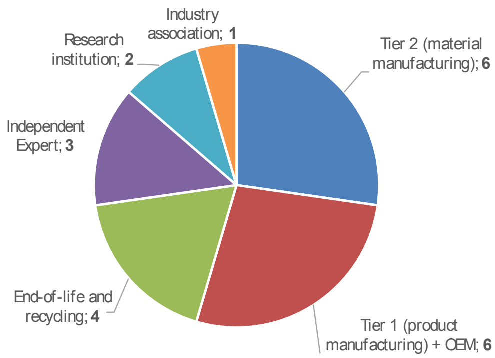

**Figure 1. Number of consulted stakeholders, by main activity within the titanium metal supply chain (*OEM: original equipment manufacturers*).**

In parallel to this qualitative work, we obtain quantitative data on repairing, reusing and recycling within the value chain. In our showcase, we are interested in secondary flows; more precisely, data is collected on how titanium scrap flows between countries, sectors, and value chain stages.

Because we want to evaluate the effect of circularity on the EU's strategic autonomy with respect to third countries, the first step of our analysis is to quantify material flows between geographies. To this end, international trade statistics (e.g., UN Comtrade) constitute a reasonable starting point. These contain information on imports and exports for all countries in value (USD) and mass (kt) terms[2], using a harmonised goods classification. Our subjects of interest are trade flows from Harmonised System code 8108.30 (*Titanium waste and scrap*).

Regrettably, import/export statistics are country aggregates that do not shed any light on the quality of the scrap (suitable vs. unsuitable for primary material production), the sectors where it originates from (aerospace vs. other) or the stage of the value chain at which it is created (production vs. end-of-life). Therefore, this needs to be enriched with other sources that allow for greater disaggregation.

Our solution is to combine macroeconomic statistics with micro-level data such as trade records from customs agencies around the world. These sources, which are often processed and merged by third parties (e.g., Standard & Poor's, Descartes Datamyne) contain detailed shipment-level information including the name of the shipping and consignee companies, their sector of activity, and a full description of the content of the shipment, along with the country of origin/destination and the trade codes found in macro statistics. By applying text mining and quantitative techniques, all the former allows to gain a better understanding on the composition of international titanium flows.

A final word of caution: Our analysis requires merging different data sources which do not necessarily share the same structure, depth or geographical coverage. We are aware of this challenge and document the procedure as transparently as possible.

## Results

Our research is ongoing. Preliminary results include a detailed Ti supply chain diagram complemented with drivers and barriers to circularity in the EU, and a quantitative estimation of Ti scrap trade flows, which can be used to develop future circularity scenarios.

*Qualitative results: Titanium metal supply chain and circularity drivers and barriers*

The first set of results derives directly from the qualitative data gathered in the stakeholder consultation. Figure 2 shows a detailed diagram of the titanium metal supply chain including linear and circular processes, from extraction and processing to manufacturing, use and end-of-life. A selection of specific drivers and barriers for increasing circularity in the EU, the details of which are provided in Table 1, is embedded in the diagram at the relevant flows/stages.

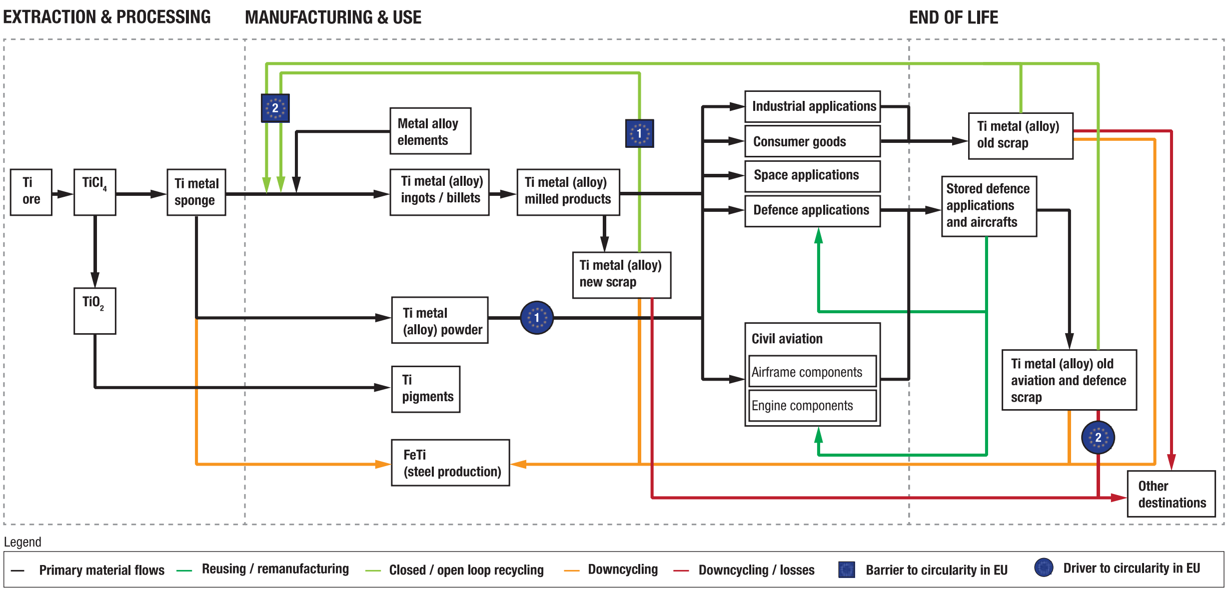

**Figure 2. Diagram of the titanium metal value chain, showing drivers and barriers to titanium metal circularity in the EU.**

[2] Throughout our exercise, we use mass flows.

| Barrier / Driver | Type | Description |
|---|---|---|
| EU circularity barrier 1 | *Economic* | EU Tier 1 companies and OEMs are required to send back the Ti metal scrap generated in manufacturing to Tier 2 producers located overseas. |
| EU circularity barrier 2 | *Technical* | Ensuring quality and safety of recycled scrap for aviation and defence applications requires additional processing before ingot remelting, with a technology not yet widely deployed in the EU. |
| EU circularity driver 1 | *Economic* | Opportunity to recover more titanium metal embedded in the frame of aircraft that reach end-of-life in the EU, currently mixed with other metals and downcycled because recovery is not cost-effective. |
| EU circularity driver 2 | *Technical* | Advances in additive manufacturing might allow reducing up to 90% of Ti metal needed in manufacturing of aircraft components in the EU. |

**Table 1. Preliminary list of identified drivers and barriers to titanium metal circularity in the EU.**

In this line, we will also provide a set of quantitative and qualitative assumptions derived from the interviews and the micro-level data, as shown in Table 2.

| Topic | Assumption |
|---|---|
| *Aerospace* | Amount of old scrap from end-of-life aircraft negligible with respect to new scrap in primary production. |
| *Aerospace* | Most EU-produced aeronautical scrap (*X%*) are shipped to the US. |
| *Scrap* | Scrap content in primary production:<br><br>- [*Older technology]* Vacuum Arc Remelt (VAR) furnace: *Y%.*<br>- [*Newer* technology] Cold hearth - plasma: *Z%.* |
| *Scrap* | Most EU exports of scrap (*N%*) are vacuum-grade for remelting. |

**Table 2. Examples of assumptions derived from stakeholder consultations and micro-level data.**

*Quantitative results: estimation of Titanium scrap trade flows to develop future scenarios*

The second set of results consists of an overview of EU titanium scrap flows. We start by processing macroeconomic data to have an aggregate view of international linkages in terms of material volumes traded (Figure 3); mass flows are then disaggregated at the sectoral, grade and new/old level using the insights obtained from qualitative data and micro-level sources. As discussed in the previous section, these estimates will be subject to some degree of uncertainty derived from the combination of data sources.

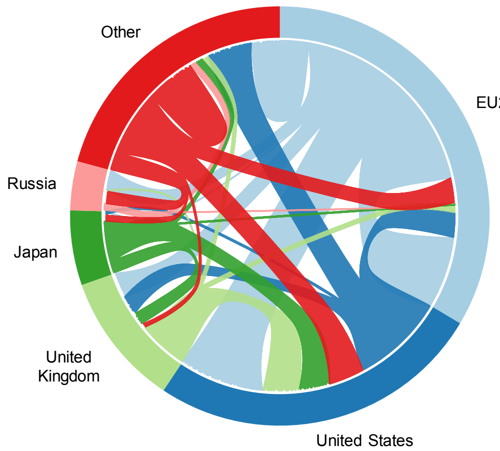

**Figure 3. Global titanium metal scrap export flows (gross weight, kt) for 2021 (Source: JRC and Fraunhofer ISI from UN Comtrade data).**

Figure 4 sketches a fictional example of one possible disaggregation. According to our findings in Tables 1 and 2, aerospace OEMs located in the EU currently ship a large share of high-quality (vacuum) titanium scrap to third countries –namely, the US and the UK- because of the buyback agreements in place with Tier 2 manufacturers from overseas, which also have the technology to process such scrap at large scale. Aerospace applications consume circa 70% of the EU's titanium metal demand, while other sectors producing high-quality scrap (e.g., defence, healthcare) make up for a much smaller percentage, roughly 4% (Louvigné, 2021).

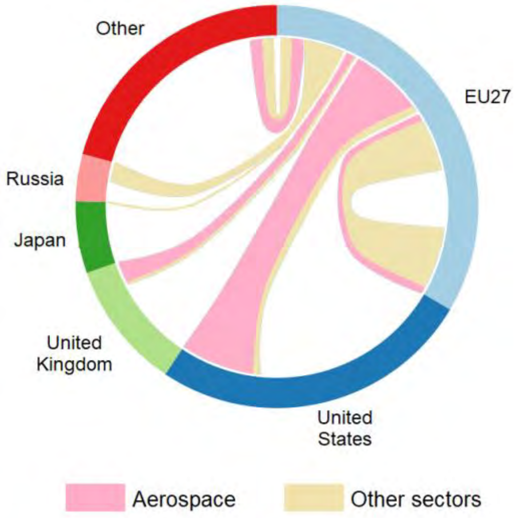

**Figure 4. Fictional disaggregation of EU titanium scrap export flows (in mass terms) based on micro datasets and qualitative insights.**

Consequently, the lion's share of EU shipments of vacuum-grade scrap to the US and the UK will stem from aerospace applications. In contrast, most of the intra-EU trade flows and shipments to the rest of the world (with less scrap processing capacity than the US and the UK) will probably consist of lower-quality scrap, also from less demanding applications, which is often downcycled for ferrotitanium (FeTi) production and not as stringently subject to buyback agreements.

Last but not least, understanding the structure of scrap flows facilitates the conception of future scenarios for circularity and strategic autonomy that can inform policy actions. For instance, the following deviations from the present *status quo* may be envisaged:

- *To what extent could the EU recover more old scrap from end-of-life aerospace applications that is eligible from remelting?*
- *Could the EU retain a larger share of high-quality, domestically produced titanium scrap by discarding buyback agreements?*

Our insights allow to map these scenarios onto variations in titanium scrap flows. By way of example, Figure 5 depicts how these could react to a hypothetical reduction in buyback agreements of EU companies with third countries, combined with larger recovery of intra-EU scrap from end-of-life aircraft. Under the assumption that some trade between EU Member states takes place (e.g., because one country concentrates most of the scrap processing capacity), the combination of both effects would result in a shift from extra-EU to intra-EU exports.

This type of scenarios can easily be fed onto economic and environmental models. The modelling stage would allow to evaluate the potential effects of enhanced circularity in the value chain on the EU's economic structure (e.g., GDP, industrial value added, employment) and environmental footprint (e.g., $CO_2$ emissions). We are currently building a preliminary exercise using in-house, environmentally extended input-output models, designed to evaluate sustainable production and consumption policies. The details and findings of the analysis will be disseminated in a separate publication.

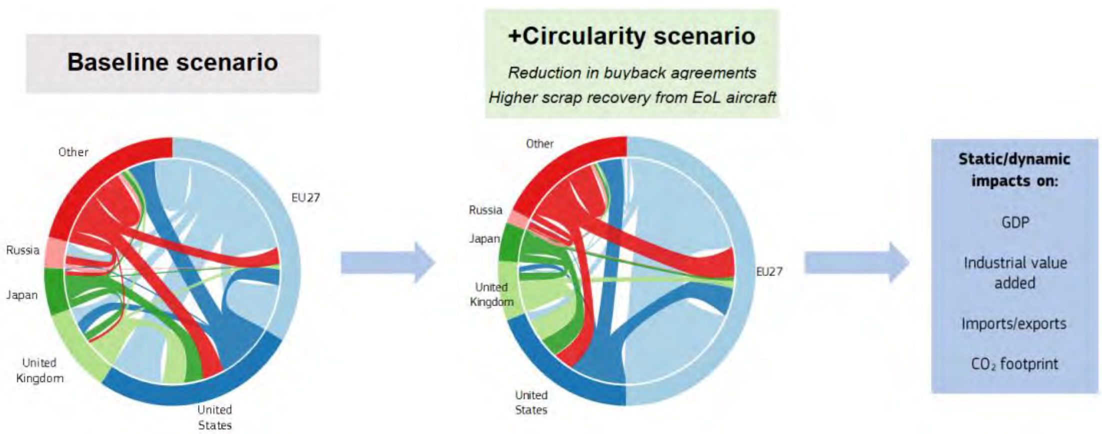

**Figure 5. Example of increased circularity/strategic autonomy scenario based on cross-country export flows (in mass terms) of titanium scrap.**

## Discussion and conclusions

This paper enhances theoretical knowledge by combining quantitative and qualitative methods in a material-specific fashion, thus achieving a level of detail unfeasible under more transversal approaches, which consider multiple products and equipment. The former notwithstanding, our method is designed to facilitate scalability to any material or technology, including any subset of the EU List of Critical Raw Materials (e.g., wolfram, cobalt…).

From a practical standpoint, our results contribute to a better understanding on how to advance circularity in the titanium metal value chain in the EU. Major stakeholders would benefit from increased foresight while tuning in to potential regulatory developments. Precisely, from a policy perspective, our work facilitates the conception of future scenarios and informed targets –which are the scope of subsequent studies-, in line with the objectives of the second Circular Economy Action Plan (European Commission, 2020a). Looking ahead, our study has the potential to feed into the policymaking process stemming from the recently published EU Critical Raw Materials Act (European Commission, 2023b).

## Acknowledgments

We are grateful to Luis Tercero and Denis Stijepic (Fraunhofer ISI) for their contribution to the mapping of scrap flows, as well as to the participants in the 1st IRTC conference (Lille, February 2023) for their insightful comments.

# Design and implementation of an innovative business model based on repair as a hobby

**Alex Bunodiere**[(a)], **Joost Duflou**[(a,b)]
a) KU Leuven, Department of Mechanical Engineering, Celestijnenlaan 300A, 3001, Leuven, Belgium,
b) Member of Flanders Make

**Keywords**: Repair; Hobby; Business model; Circular economy.

**Abstract**: The promotion of a circular economy requires efficient resource and process management to reduce waste. Repair plays a crucial role in achieving this goal as it improves resource efficiency. However, the out-of-warranty repair rate of electronic appliances is presently inadequate due to limited repair options, namely professional repair, repair cafes, and self-repair, each having its associated challenges, such as high costs, low frequency, or strong skill dependence. This paper proposes a new repair option called "Hobby repair," which addresses a major gap in the repair market and capitalizes on the notion that repair can be a hobby performed at home, typically during one's free time. The targeted hobby repairers would be those with skills and free time and a passion for a particular product group. The paper presents four sub-models within the hobby repair approach, each with its opportunities and solutions. Together, these models enable hobby repairers to earn a decent wage while engaging in their hobby, increasing the pool of available repairers, and lowering repair costs offered to customers. The author then conducted a real-world trial of the four sub-models proposed in this paper. The trial revealed that hobby repair has the potential to generate a revenue of approximately €18/hour, providing an additional source of income for repairers and bridging the gap in the repair market with a device repair rate of approximately 70%. The trial also identified various opportunities and challenges, which require further research for addressing.

## Introduction

The repair rates of consumer electronics and household appliances that are no longer under warranty are insufficient to achieve a truly circular economy. This is because replacement can be a more affordable, convenient, and desirable option (McCollough, 2007). Even environmentally conscious consumers may opt for replacement over repair due to these factors (Sabbaghi et al., 2016). Therefore, any initiatives aimed at increasing repair rates must address at least one of these issues in a manner that would incentivize consumers to opt for repair.

The hobby repair idea addresses the high cost and lack of repairers by building a new business model where previously underutilised potential repairers, such as students and retirees can be equipped to repair products as a hobby.

This paper first discusses the currently available repair options in Belgium, after which the hobby repair idea is explained in detail followed by the sub-models that hobby repairers could use. Lastly, the practical implementation of this idea is detailed together with the challenges and opportunities observed.

## Available repair options

### *Professional repair*

Typically available repair options can be categorized into three groups, with the first being professional repair. This involves the customer taking his/her device to the original equipment manufacturer (OEM), to a certified professional repairer, or to the distributor from whom the product was purchased. These options usually offer a high-quality repair within a reasonable timeframe, depending on spare part availability. However, the cost of professional repair is often higher than the willingness to pay (WTP) for repair, which is typically 18-35% of the original purchase price depending on the product group (Fachbach et al., 2022). At such a high cost, the consumer may choose to purchase a new device instead, which comes with a longer warranty, newer features, and more peace of mind (McCollough, 2007). In such a scenario, the user's decision may be influenced by the age of the device, frequency of usage, type of device, and other factors. Research indicates that in such cases, users may not be willing to pay the high repair cost and may opt for replacement.

*Repair café*

Another option available to consumers, particularly those seeking a more affordable option, is a repair café. This involves volunteers who are passionate about repairing devices gathering in a common space, often supported by local cities, repair organizations, or volunteers. The repair café provides tools, consumables, and workspaces for free to repair devices. While this is an excellent option for many people, it has several limitations. The primary limitation is that it is volunteer-based, which limits the frequency and duration of the repair café. Another issue is that a wide variety of products is typically accommodated, leading to a wide variety of devices needing repair (Moalem & Mosgaard, 2021). While this may be positive from the repairers' perspective as it keeps things interesting, it also limits their specialization.

*Self-repair*

Finally, consumers also have the option to repair their own devices or have a family member or friend repair the item for them, which falls under the category of self-repair. In this case, the repair is also free, like the repair café example (excluding parts and consumables), but it relies on the willingness, technical skill, and available repair resources of the consumer or friend. Due to a possible lack of knowledge or tools, this type of repair carries a higher risk of damage to the product (Moalem & Mosgaard, 2021). The time to repair may also be longer depending on the skill level of the repairer.

The diagram below (Figure 1) illustrates how each of the aforementioned repair options compares based on repair cost and time. Upon examination of the graph, it is clear that there is a gap in the market between the free options and professional repair, with the only option available to the consumer being either free repair with conditions or expensive repair. This gap serves as the basis for this research.

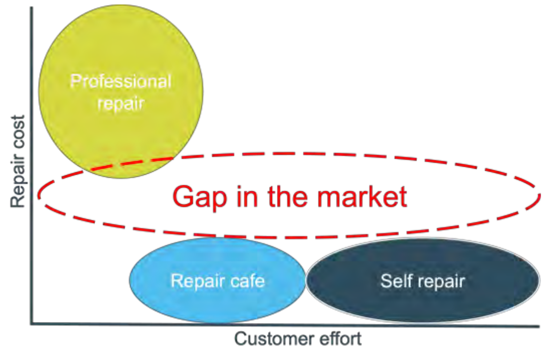

**Figure 1. The perceived gap in the current repair market.**

## Hobby repair as a concept

The emergence of the repair gap in the market has led to the development of a novel business idea, labelled “Hobby repair”. This model capitalizes on the idea that repairing something can be an enjoyable and engaging activity, particularly when it pertains to a product category of personal interest to the repairer. While repair cafes have a limited time frame for repairs, the hobby repair model enables repairers to receive devices for repair that fall within their areas of expertise and interest, and which can be repaired in their own time and space, resembling a hobby.

This model offers the benefit of repairing devices at a lower cost than a professional repair service, while still maintaining a high level of quality due to the repairer's familiarity and enthusiasm with the device. Moreover, the hobby repairer can earn a reasonable income compared to a voluntary repair cafe, making it an easily scalable business idea. The major trade-off compared to professional repair is the total repair time, which may be longer due to the hobby nature as the repairer will work when he/she chooses to partake in the hobby.

In terms of device selection for the proposed hobby repair business model, the focus should be on devices that are portable and not too bulky. Additionally, the devices should not be too cheap, as this would result in low profits for the repairer. As a result, large household appliances such as washing machines, dishwashers, fridges, and ovens are likely not suitable for this model. Similarly, devices that are priced below €50 - €100 may also not be viable, unless the hobby repairer has a specific interest or expertise in repairing such devices.

The ultimate goal of the hobby repair business model is to create a starter package that enables interested individuals to begin repairing devices as easily and quickly as possible.
In the context of the hobby repair model, various channels for obtaining repairable devices have been evaluated in a practical trial conducted by the author. The utilization of multiple sources of devices enhances the diversity of devices available for repair, thereby ensuring a consistent supply of repairable devices. However, each channel has its own merits and limitations.

### 1. *Buying, repairing, and selling broken devices*

One of the sources of devices for hobby repair is the purchase of broken or malfunctioning devices from second-hand platforms. These devices are repaired by the hobbyist and then sold back on the same platforms. While this option has the highest initial cost and risk, it was observed in a real-world trial conducted by the author that the quality of the devices is the highest. The profitability of this option can vary greatly depending on the initial cost and selling price of the repaired devices. Additionally, logistics are required to transport the devices to the hobbyist's home.

### 2. *Collecting, repairing, and selling free devices*

This option involves acquiring devices from various sources of free devices, such as local second-hand platforms, free exchange platforms, or recycling parks. While recycling centres and container parks typically have an almost unlimited supply of broken devices to repair and sell, access to these devices is often restricted. Working with a third party can help overcome this issue, as explained in the fourth model, which is the third-party partnership. The repaired devices are then sold through second-hand platforms. This option incurs no initial cost, but the quality of the devices can vary significantly, with many devices missing parts that may be expensive or difficult to find. Furthermore, finding the devices can also be challenging, and logistics are required to transport the device to the repairer's home.

### 3. *Repair as a service*

This model operates similarly to that of a professional repairer, with the primary difference being the repair lead time and the cost of repair. In this case, customers contact the repairer about a device needing repair. The device is either collected or delivered, repaired and then returned to the customer for a predetermined price. This option has little risk, except if the device breaks during repair or the customer refuses to pay. Unlike the two previously discussed options, this case typically has little to no logistics, and no buying or selling of devices, which may be more desirable for the repairer, as he/she can focus solely on the repair. However, acquiring customers can be challenging, but there are existing platforms that can be utilized to find customers.

### 4. *Third-party partnership*

Partnering with a 3rd party such as a thrift store is a model that provides access to broken devices and a selling platform. Thrift stores often lack skilled workers and can benefit from hobby repairers who are solely focused on repairing. This model eliminates the need for logistics, buying, and selling for the hobby repairer.

The figure below (figure 2) shows how each sub-model relates to the other in terms of potential revenue and effort.

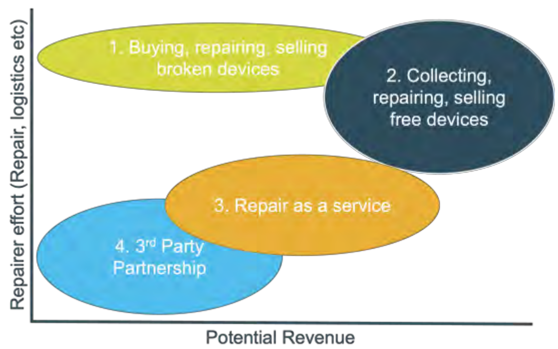

**Figure 2. Hobby repair sub-models.**

## Hobby repair in practice

To test the business model in real-world settings, the author conducted a trial from May 2022 to March 2023 focusing on repairing fully automatic coffee machines. This product category was selected due to the author's interest and the complexity of the machine, which includes multiple mechanical, electrical, and plumbing systems that present an engaging repair challenge. The trial tested all four business model subtypes, each with varying degrees of success.

The first sub-model, buy-repair-sell, involved purchasing one broken fully automatic coffee machine for €60 and repairing it for less than €10 over 6 hours of work. The machine is now worth roughly €400 based on second-hand value. However, another purchase for €60 resulted in a less successful outcome, as the machine requires a part that is no longer available, potentially resulting in a loss of €60. This highlights the risks associated with this sub-model, as there is a need to invest capital and time to acquire the machines, but also the potential for higher rewards due to the higher quality of the device.

The collecting-repair-selling model was tested next, where devices were obtained from various sources such as freecycle (a community free collection platform) and internal contacts. Out of the five acquired devices, two were irreparable due to lack of spare part availability and were disassembled for future repairs, while two were repaired and sold with an approximate profit of €80 each after 6 hours of repair time. The last device awaits one part that requires 3D printing and once completed, should sell for €300 with a parts cost of €50 and 8 hours of repair time. This model shows promise but requires logistics and acquiring devices can be challenging, but it comes with low risk since devices are obtained for free.

The repair as a service sub-model proved to be the most profitable, with seven coffee machines repaired and a 100% repair rate due to the high quality of machines given for this model. This sub-model was facilitated using a consumer-to-consumer (C2C) platform called Ringtwice which pairs citizens seeking a service with citizens offering that service, in a fully legal and insured way (How It Works - Ring Twice, n.d.). The total time spent on repairs was 36 hours, resulting in a total profit of €667. This translates to an hourly wage of €18.53, which falls between the free repair and professional repairer rates, the target range for this business model.

The 3rd party partnership was with Kringwinkel Hageland, a thrift store based in Belgium that repairs a variety of goods, including electronics. As a social employer, they benefit from government subsidies for their labour, resulting in a lower wage cost, but with a limit on skills and staff availability (Moeseke et al., 2022). They have a large storefront presence in Belgium resulting in 4.5kg of reused items per inhabitant per year (*Choose Second-Hand, Go for Kringwinkel*, n.d.). They acquire products from various sources, but their main bottleneck is electronics repair due to limited staff availability, as shown in Figure 3 below.

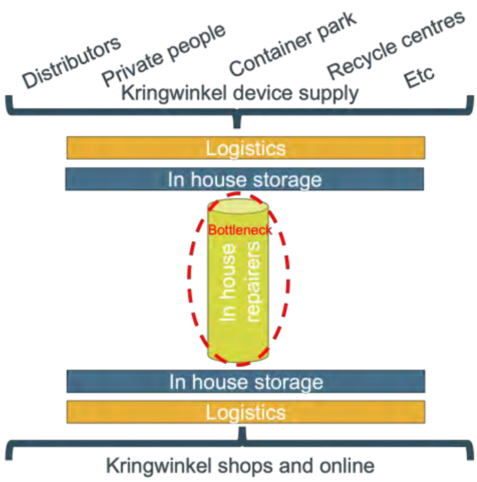

**Figure 3. Kringwinkel Hageland bottleneck.**

A partnership with hobby repairers of various specialities would therefore help alleviate this bottleneck. To demonstrate this, ten coffee machines were selected by the author and delivered to his house by Kringwinkel, eliminating the need for device procurement and logistics. All the machines were repaired, with some requiring parts that were paid for and delivered by Kringwinkel.

After 2 months of repairing the coffee machines, all 10 were fixed with an average repair time of 4 hours and returned to Kringwinkel. As of March 14th, 2023, 8 of the 10 machines had been sold, resulting in a revenue of approximately €1600. If the revenue was split equally between the repairer and Kringwinkel, the repairer would receive €800, resulting in an hourly wage of €20. However, since there was no payment system in place at the time of the trial due to the tax issues mentioned below, the work was done on a voluntary basis.

One key difference between this sub-model and the others is the issue of warranty and taxes, which will be discussed next.

## Financial aspects

*Taxes*

Payment of taxes on income earned from repairing is a necessity and country dependent. When selling devices on a second-hand platform in Belgium, there is a grey area between individual and business operations, summarised as:

> "*It is not possible to determine concretely from when it is no longer "normal" for the tax authorities and the proceeds become taxable*". (Test-aankoop, 2021)

As such, selling repaired devices on second-hand platforms should be an exception rather than the norm.

In the repair as a service sub-model, the author utilized the Ringtwice platform to provide C2C repair services. This platform offers a lower tax rate of 10.7% up to €7170, as well as basic insurance coverage for damages caused by the repairer, and a means of connecting repairers with customers.

Regrettably, no payment method for the 3rd party partnership was established, thus the work was voluntary which has little benefit to the repairer. Future partnerships would require a business-to-business (B2B) relationship, which adds complexity and cost, deviating from the hobby repair idea. One option that is yet to be explored is that of "Flexi-job" where the 3rd party could hire these hobby repairers in a more casual but fully legal way, this will be explored in the future(*Flexi Job | Flanders.Be*, n.d.).

*Guarantee responsibility*

Repair guarantee varies across sub-models. For the first two, there is no legal framework, hence the repairer might offer a goodwill guarantee. The third sub-model is similar, but the customer can give a review, impacting the repairer's profile positively or negatively.
In contrast, the third-party partnership with Kringwinkel Hageland includes a legal obligation to provide a one-year warranty on repaired devices. Thus, the repairer is responsible for repairing devices under warranty during this period. Kringwinkel remains responsible for logistics and parts ordering. To formalize this relationship, a contract needs to be established between the repairer and the third party. It should also include provisions for the repairer's early departure from the partnership, which is currently a work in progress and has not been determined by the time of publishing.

## Conclusion

The proposed business model aims to address the shortage of affordable repair services by increasing the number of available repairers. During the trial period, 27 fully automatic coffee machines were received through the various sub-models, with 19 fully repaired (70%) and the remaining either disassembled for parts or still in the repair process. The trial run demonstrated its feasibility and potential appeal to customers and hobby repairers alike. The revenue earned by a hobby repairer would depend on the type of product being repaired, with fully automatic coffee machines in the case study earning approximately €18/hour. This hobby repair model offers an engaging and rewarding activity while promoting environmental sustainability.

However, challenges remain, particularly concerning taxes and guarantees. These challenges vary across countries and must be addressed to implement this model on a larger scale. This model could be particularly effective in countries with an ageing but skilled population where high wages cause replacement instead of repair to be prevalent. Through the hobby repair concept, these skilled retirees could help lower the repair cost and shift the balance back to repair.

b) University of São Paulo, São Carlos, Brazil

**Keywords**: Circular economy rebound; Circular ecosystem; Rebound effect; Value recovery.

**Abstract**: In Circular Ecosystems, autonomous but interdependent actors jointly strive to create a circular value proposition. The complexity of these ecosystems arises from many interactions and feedback loops between actors, variables, solutions, and projects. In addition, interventions in the ecosystem can cause rebound effects. In this way, an analysis of these interdependencies and feedback loops is necessary for a deep understanding of the system, thus supporting practitioners and researchers in obtaining valuable information in the effective transition of the Circular Economy. In this sense, considering that the Glass Ecosystem has become fundamental for waste management and value recovery in Brazil, the main objective of this study is to uncover the complexity of the glass value recovery ecosystem by identifying the causal relationships among the ecosystem attributes and the possible circular economy rebound phenomenon that came from the circular transition. We carried out a thorough case study, including semi-structured interviews and document analysis, and thereafter we used the system dynamics approach to build a model of the ecosystem. We highlight four critical points to achieve the ecosystem goal, Ecosystem emergence, Ecosystem Alignment, Ecosystem Scaling Up, and Value Recovery Innovation, which operate at different levels of circular economy implementation and can lead to rebound effects. Our ecosystem analysis revealed six critical circular economy rebounds in the environmental and social spheres.

## Introduction

The increasing disposal of waste and the excessive consumption of natural resources are among the main challenges to be overcome by today's society. In this context, waste management emerges as an opportunity for businesses to recover value and reduce the impact caused by their activities (Sanches et al., 2022). The Circular Economy (CE) transition requires implementing a waste management system prioritizing value recovery. This entails the closing of material loops and the extension of their life cycles, intending to maximize the extraction of value from these resources (EMF, 2013). However, to understand the complexity of material value recovery by society, it is important to expand the study to the theoretical lens of circular ecosystems and their attributes (Adner, 2016; Trevisan et al., 2022).

A circular ecosystem comprises a set of autonomous but interdependent actors who drive collective efforts to create a circular value proposition (Trevisan et al., 2022). To materialize the circular value proposal, the actors must direct their activities towards a commom sustainable goal, constantly share resources and information, manage the flow of data and materials, promote better resource use, and constitute adequate governance (Trevisan et al., 2022; Konietzko et al., 2020).

Circular economy rebound (CER) has become an increasingly important topic as it has the potential to reduce the benefits generated by circular economy or lead to unintended negative impacts (Castro et al., 2022). However, identifying CERs can be challenging, and many circular economy models do not take this concept into account. In a circular ecosystem, CERs can be either direct or indirect. Direct rebound effects occur when lower costs of products/services lead customers to use more of them, while indirect effects imply that the improvement made will affect other goods production or consumption (Sorrell & Dimitropoulos, 2008; Zink & Geyer, 2017). Other unintended consequences can relate to social (Warmington-Lundström & Laurenti, 2020), macroeconomic, or transnational aspects (Freeman, 2018). Therefore, while CERs may not be manageable from the perspective of a single firm, they need to be understood as a phenomenon that occurs between firms with their relationships of interdependencies and co-creation of value.

To mitigate potential rebound effects, it is crucial to understand the dynamics of circular ecosystems and develop strategies that anticipate and address them. By doing so, we can maximize the positive impacts of circular ecosystems while minimizing their unintended consequences, ensuring that the circular economy remains a sustainable and effective solution for creating long-term value.

The beverage industry is one of the main socioeconomic sectors in any country, characterized by high revenues (ABIA, 2021) and significant job creation (Cervieri Júnior et al., 2014). Among its challenges, waste treatment is considered one of the most critical given its negative consequences but also for its positive potential (Barquete et al., 2022). The high recycling potential of glass packaging, being fully recyclable and widely produced and consumed (Niero et al.,2017) is undermined due to its low added value and high logistical costs, affecting the economic viability of its post-use.

Glass packaging is a significant component of Brazil's circular value recovery ecosystem. The actors in this ecosystem share the responsibility for waste management, and the value recovered from the process is divided between them. Despite its importance, the ecosystem's capacity to operate was limited, prompting recent legislation aimed at improving the macroeconomic outcomes associated with such ecosystems. As relationships shift and new variables emerge, additional actors engage within the ecosystem, its dynamics becomes more complex and increasing the likelihood of a CER (Castro et al., 2022). As such, it has become crucial to recognize the interrelationships and interdependencies within this circular ecosystem and understand its dynamics to develop appropriate strategies for a successful transition to a circular economy. By strengthening virtuous cycles and minimizing the rebound effect, this ecosystem can achieve optimal outcomes.

The primary aim of this study is to elucidate the intricacies of the circular glass value recovery ecosystem by identifying the causal relationships between ecosystem attributes and the possible rebound effect resulting from the transition to a circular economy. To achieve this, we utilized causal loop diagrams, which employ a system dynamics approach that has proven to be highly effective for this type of analysis. In the following sections, we provide a detailed account of our research methodology and present the results of our investigation.

## Material and methods

Given the lack of empirical data that capture the CER in a circular value recovery ecosystem, a qualitative case research approach is applicable (Eisenhardt, 1989, 2021). This paper used two data sources to understand the dynamics of RE in the ecosystem: interviews and documental. Semi-structured interviews were conducted with Brazil's leading glass value recovery ecosystem actors. We selected the firms based on their functions and influence on the ecosystem's circularity; afterward, applying the snowballing technique (Wohlin, 2014), we selected new firms. In total, 14 heterogeneous firms in the glass value recovery ecosystem were selected. All interviews were recorded and transcribed to enhance the data analysis process. We collect 85 data archives including reports, news, webpages, and environmental legislation, to complement the analysis process.

We adopted a data analysis process based on coding cycles (Gioia et al., 2013), using the MAXQDA software. In the first coding cycle, informant-based codes were created. Following, the codes were refined, and we aggregated the codes in dimensions to promote the understanding of the ecosystem structure and the occurrence of CER.

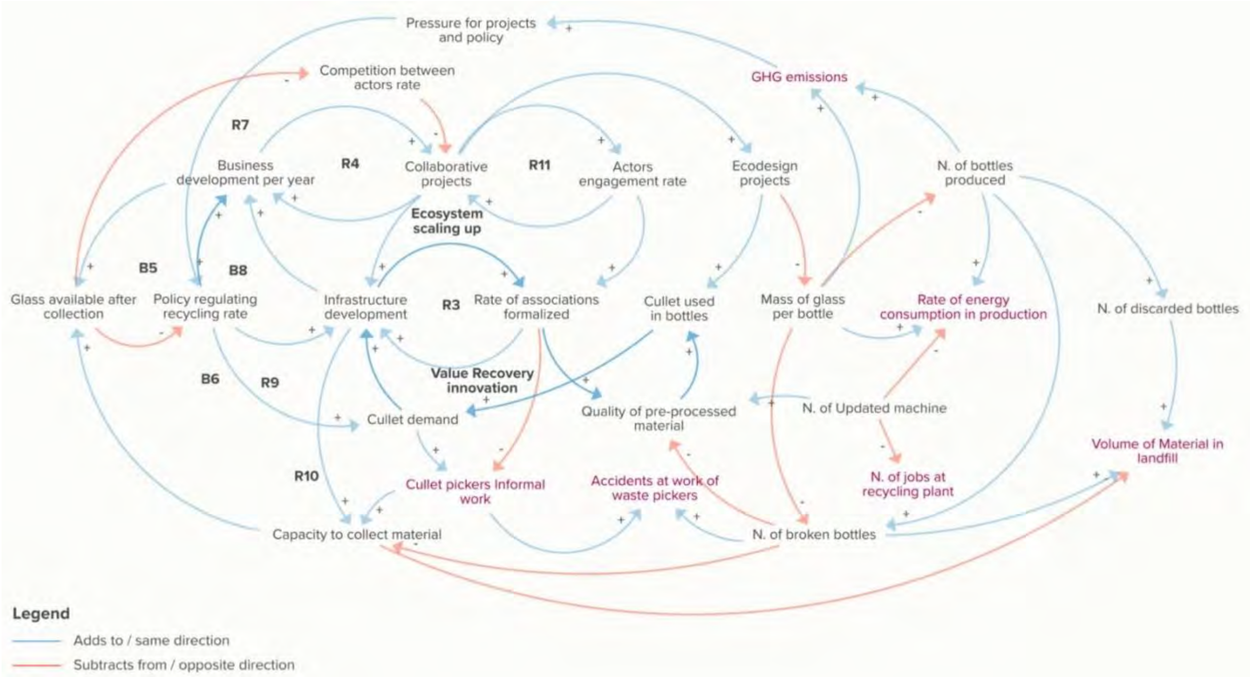

**Figure 1. CLD for the ecosystem dynamics and the circular rebound effects (in red).**

The system dynamics approach was used to build a model of the ecosystem structure that facilitates the reading and understanding of the interaction between mechanisms of the CER phenomenon. In line with (Mbavarira & Grimm, 2021), we used the software Kumu to develop a Causal Loop Diagram (CLD). CLD is an essential visual tool to identify relationships between different variables (Bassi et al., 2021; Guzzo et al., 2021) and shed light on ecosystem dynamics. The CLD map was developed based on the triangulation of primary and secondary data and from discussions with experts, ensuring more rigor to the theoretical insights. To develop the CLD, the steps proposed by (Sterman, 2000), and the guide provided by Guzzo et al., (2022) were followed.

## Results

The central result is a CLD (Figure 1) synthesizing our findings. The CLD illustrates the feedback loops among variables from different aspects of the ecosystem. We reveal four critical functions to achieve the glass value recovery ecosystem's goals (i.e., increase cullet usage, reduce costs, emissions, and the extraction of raw materials): Ecosystem prominence emergence (Figure 2a), Ecosystem Alignment (Figure 2b), Ecosystem Scaling Up (Figure 2c), and Value Recovery Innovation (Figure 2d), which operates at different levels of CE implementation and may lead to Circular economy rebound (CER).

Using post-consumer glass is not only a sustainable business strategy but also a profitable one because it lowers production costs. To comply with the Brazilian national solid waste policy (Política Nacional de Resíduos Sólidos (PNRS), 2010) requirements, firms must recycle at least 22.5% of the products they sell. This includes beverage and bottlers manufacturers, retailers, and other industry firms. In addition to lowering waste, using cullet glass reduces greenhouse gas emissions associated with the production of bottles. This scenario makes bottle design and production a critical area for sustainability improvements within the beverage industry.

### *Four critical ecosystem functions*

The **Ecosystem prominence emergence** has significant implications for CE and sustainability. By enabling material and value flows, the ecosystem promotes collaboration among various stakeholders, including companies, consumers, government agencies, and startups. The focus of this collaboration is initially on developing the necessary infrastructure and material recovery capabilities (Figure 2a). The entry of new firms and business models complements the ecosystem's activities and improves overall outcomes.

The **Ecosystem alignment** function aims to align strategies, behaviors, and goals to maximize material recovery capacity. The alignment among various actors is profoundly changing due to new regulations governing the sector and outlining shared responsibility. The actors' involvement is essential for infrastructure growth and improving the amount and quality of recovered material. When the more closely. These projects are typically developed through collective efforts and address multiple objectives, such as enhancing consumer awareness, formalizing the activities of waste pickers and cooperatives, building collection infrastructure, establishing effective material transport mechanisms, and constructing new recycling plants.

The **ecosystem scaling up** critical function is associated with the challenges of increasing recycling increasing within the ecosystem. The

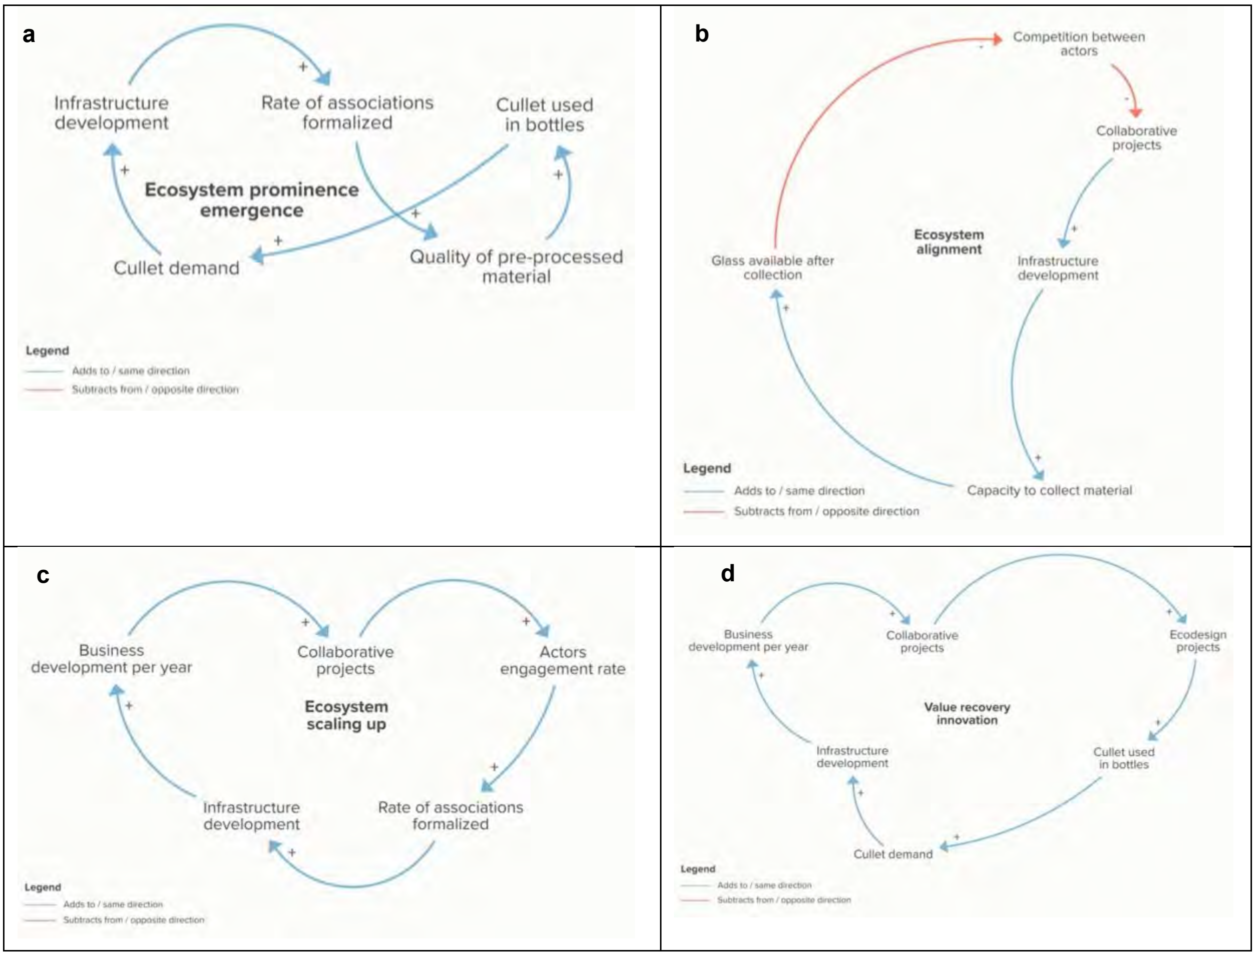

**Figure 2. CLD of the Four critical ecosystem functions a) ecosystem prominence emergence; b) ecosystem alignment; c) ecosystem scaling up; d) value recovery innovation.**

barrier of competition is balanced, and actors can collaborate on projects, the amount of material to be recycled in the ecosystem increases.

The rise of new actors within the ecosystem has introduced novel responsibilities, including developing projects to increase material collection capillarity and involve consumers low market value of glass waste can pose a challenge for actors who are already engaged in recycling other materials to enter the ecosystem, because of the material price and the need for space for storage. Additionally, the material's separation and contamination can influence the final product's quality and hinder its use. Furthermore, reverse logistics can pose transportation challenges, as the weight and volume of the material, as well as the mode of transport, can make it difficult to recover value over long distances. To address these challenges, the actors develop projects to engage actors, leading to social will encompass critical to scaling up the use of glass waste in the ecosystem and achieving the associated sustainability benefits.

The least critical function highlighted is **Value recovery innovation.** A demand for more cullet by bottle manufacturers presents opportunities across multiple fronts. Some glass bottle manufacturers have implemented value recovery innovation within the value recovery ecosystem to capture culets involving various actors. Such initiatives typically entail the participation of a bottle manufacturer, a beverage manufacturer, a waste management startup, cooperatives, and companies developing technologies to overcome existing collection challenges. Startups typically propose projects, which companies then adopt. For companies, increased project development translates to increased material availability and improved business prospects.

*The circular economy rebound*

The complexity of a CE ecosystem arises from the interdependent interactions and combinations of solutions, variables, actors, and projects. While we highlight four important feedback loops that represents the critical function of the ecosystem, Fig. 1 illustrates that many others are present. These loops indicate numerous interactions between system variables, making it challenging to analyze them in isolation. As multiple variables change simultaneously, they can impact the system's behavior, making it difficult to predict. As such, a comprehensive understanding of the system requires analyzing these interdependencies and feedback loops, which can provide valuable insights for business practitioners and researchers alike.

Our ecosystem analysis revealed five circular rebound effects (CER). These CER are summarized in Table 1.

| **CER** | **Initiating mechanism** | **Developing mechanism** | **Mitigating Mechanism** |
|---|---|---|---|
| CER1<br>Increase of informal work | Demand for material to recycle; | Higher glass waste prices; | Policies directed at waste pickers:<br>Infrastructure development; |
| CER2<br>Accidents at work of waste pickers | Demand for material to recycle;<br>Bottle redesign; | With informality, there is a lack of knowledge and safety equipment | Policies directed at waste pickers;<br>Infrastructure development;<br>Security Training; |
| CER3<br>Rise of energy consumption in production | Bottle redesign; | The same amount of material can produce more bottles | Infrastructure development;<br>Combination with reuse strategy; |
| CER4<br>Increase of volume of Material in landfill | Bottle Redesign to use less glass | More breakages, and more incorrect disposal. | Infrastructure development;<br>Combination with reuse strategy; |
| CER5<br>GHG Emissions growth | Increasing cullet demand;<br>The need to collect glass in locations far from the factories | Poor infrastructure to reprocess materials. | Infrastructure development;<br>Synchronization of logistical activities; |
| CER6<br>Decrease of jobs at recycling plant | The need of better quality of pre-processed material;<br>Increased cullet used in manufacture; | Companies invest in technologies that automate the separation of materials | Public awareness;<br>Infrastructure development;<br>Qualification of labor for other activities |

**Table 1. Summary of circular economy rebound (CER) found in the ecosystem.**

The CER1 and CER2 result from high material demand, which increases the price paid for post-consumer glass, and led to a growing number of informal waste pickers (CER1) entering landfills and other locations with poor disposal practices to collect and sell the material to various companies and collection points that offer rewards. This increase in informal waste collection work is due to the improved economic incentives of the circular economy, but it may also lead to unintended negative consequences such as increased exposure to hazardous waste and workplace accidents (CER2) due to broken glass bottles.

The packaging redesign during manufacturing aims to decrease the amount of raw material used per product, leading to thinner and lighter bottles with reduced emissions during production and transport. However, this approach also has unintended consequences. The reduced material per bottle allows manufacturers to use the same amount of cullet to produce more bottles, potentially increasing the rate of energy consumption and emissions during production (CER3). Furthermore, the lighter bottles are more fragile, resulting in increased breakage and discarded material in landfills (CER4), where many informal waste pickers work, causing more accidents (CER2).

The need for increased material recycling, compliance with recycling legislation, and limited recycling facilities in Brazil, resulted in a need to transport waste over long distances, thereby increasing GHG emissions (CER5). Furthermore, some industries' focus on pre-recycling material treatment efficiency has shifted towards automated separation technologies, reducing jobs within the recycling plant (CER6).

## Conclusions

The ecosystem approach has proven successful in achieving positive outcomes in the value recovery ecosystem. This approach has promising implications for promoting sustainable development. However, it is important to consider the occurrence of CER at the ecosystem level and implement a combination of mitigating strategies, as Castro et al (2022) highlight, to prevent societal effects. Additionally, it is important to recognize that the ecosystem complexity leads to a need for actors to align efforts in implementing circular strategies and finding governance methods. This systemic comprehension assists in the CER mitigation mechanisms.

This research shows that the CLD is a useful tool to map the CER and other ecosystem aspects, so a future step is to verify the fit of the CLD as alignment and governance toll to the ecosystem.

Future research can expand on this topic by comparing this ecosystem with others that use different circular strategies, such as bottle reuse, and exploring the effectiveness of the ecosystem in prioritizing circular strategies. In summary, the ecosystem approach presents a promising strategy for promoting sustainable economic development.

# The interior architectural design framework for shaping interior components to optimize the lifetime of building products

**Celadyn Magdalena[a], Celadyn Waclaw[b]**
a) Faculty of Interior Design, Academy of Fine Arts in Krakow, Krakow, Poland
b) Department of Architecture, Cracow University of Technology, Krakow, Poland

**Keywords**: Interior architecture; Adaptive reuse; Building product; Interior component.

**Abstract**: This paper continues the discussion on the issue of adaptive reuse design strategy which contributes to the extension of the lifetime of architectural objects, while situating this problem within indoor environment. It does introduce the Interior Architectural Design for Adaptive Reuse (IADfAR) conceptual framework. This design scheme is based on the acquisition of the selected reclaimed building products, originally making the structural elements of building or its external finishes, from the refurbished or demolished buildings, and followed by their transfer into indoor environment to form the interior constitutive components. This article discusses the main assumptions and requirements of the proposed conceptual design framework, which covers the transformation of the secondary building products into the new valuable building substance. It identifies the two perspectives from which the design model then is to be analysed. The study examines the substance context, which refers to the material potential of pre-used building products, in particular the sustainability-related problems of retaining or resources effectiveness. Then, the immaterial context, relating to intangible values represented by the salvaged building products featuring the structure of interior components, is examined. It comprises the questions of the users' perception of interior components as being specific compound products absorbing the pre-used building products, cultural references, as well as users' emotional engagement. The analysis aims at the evaluation of the effectiveness of proposed design scheme's, and the influence of proposed design scheme on the optimization of the building products lifetime.

## Introduction

The adaptive reuse, discussed within disciplines of architecture and interior architecture, concerns the development and further application of design methods to allow the existing buildings to accommodate new functions (e.g., Pleovets & Van Cleempoel, 2013; Brooker & Stone, 2004; Bullen, 2007). This environmentally-friendly design strategy, based on the remodelling and altering buildings (Brooker & Stone, 2007), conversion of existing buildings to assure their continued use (Pleovets & Van Cleempoel, 2013) within the changed functional context, contributes to the extension of the lifetime of architectural objects, which remain the central elements of the built environment.

This study, continuing the discussion on the issue of adaptive reuse in the context of optimizing the building product lifetime, situates this problem within indoor environment, appointed as internal built environment (Yeang, 2009) or near environment (McClure & Bartuska, 2007), and featuring the building's interior. The adaptive reuse strategy to expand the lifespan of building products is identified from the interior architecture perspective. It concentrates on forming the interior's structural or constitutive components (i.e. enclosures separating the inner spaces from the natural environment physically and accompanied on the inner side by various technical devices, functionally and structurally developed spatial dividers of various volumes and finishes, raised floors, integrated and suspended ceilings) with the selected building products, pre-used, discarded as useless substances, and then reclaimed. Interior Architectural Design for Adaptive Reuse (IADfAR) conceptual framework, discussed in this paper, aims at the design techniques to effectively accommodate the secondary building products within interior components, and thus extend their technical life.

The following chapter considers this design scheme with regard to its main assumptions and terms. Then, the assessment of the effectiveness of design method, examined subsequently within materiality and intangibility contexts, is followed by conclusions on the impact of proposed design scheme on the extension of building products lifetime.

## Design framework: assumptions and requirements

*Inter-setting transfer*

The IADfAR scheme is based on the acquisition of selected reclaimed building products originally making the structural elements of building or its external finishes (e.g. ceramic bricks and tiles, panels, window frames) from the refurbished or demolished buildings, followed by their transfer into the inner spaces to form the interior components (Figure 1). This process encompasses the restrained repairing, reprocessing and final introduction of these secondary products into the building substance to form interior components as their structural parts or finishes. These interior components of mixed structure, are referred to as compound products or complex "instrumented products" (Cor & Zwolinski, 2014, p. 430). They absorb the acquired building products which still prove their usefulness and potential to contribute to the performance of interior components.

This design scheme objective is the inter-setting transfer, defined as displacement of reclaimed pre-used building products from the building structure or its envelope, mediating directly with natural environment, to indoor environment, performing in spatially, functionally, as well as formally altered contexts of inner spaces, as the constituent parts of the newly conceived interior components.

*Exploring the waste state of products*

The IADfAR adds the strategy of retaining to the recognized circularity-aimed sustainable design strategies which comprise the enhancement of reliability, maintenance, repair, as well as upgradability of products (Ceschin & Gaziulusoy, 2020). This approach is focused on "extending product-life through secondary transactions" (Cooper, 1994, p. 11), and examining the possibility of resourcing of waste products "at the end of their first life span when entering a second, by being transformed, reshaped, remodelled, or reconfigured" (Hebel et.al, 2014, p. 17).

This design concept refers directly to the reduction of the throughput of resources, while preserving the cultural and emotional values associated with reclaimed products. The design scheme puts forward the following design techniques: (1) Design for Display, to attract users' attention through the unpredicted or confronting appearance of pre-used building products, (2) Design for Interaction, to build up knowledge on the impact of compound products being interior components on the natural environment, (3) Design for Connection, to provide the users with the evidence on their contribution to environmental integration due to selection of the adaptive reuse scheme to form interior components.

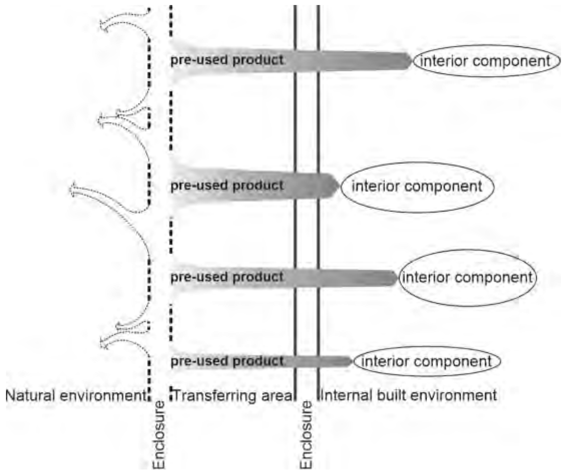

**Figure 1. Mechanism of transfer of pre-used building products: crossing the environmental boundary.**

*Accessibility*

The design of interior components, based on the acquisition and implementation of the building products salvaged from demolition, depends on the following: (1) Application potential (i.e. evaluation of the pre-used building products in relation to their possible introduction as structural parts of interior components), (2) Application (i.e. assessment of the attributes of building materials making the pre-used building products in view of their technical and environmental performance in a new context, (3) Local availability of pre-used building products, (4) Capacity of building

products to make a constituent of interior component.
The open access to the digital databases collecting above mentioned information is essential for the successful execution of the discussed design scheme.

*Commitment*
The interior architects' commitment to rationalize design interventions through the introduction of reclaimed building products into inner spaces is challenged by the users' individually inherited cultural behavioural patterns. The successful application of examined design scheme requires the occupants' acceptance and development by them a positive human-product relationship. The interior architectural design enables this if functionally upgraded, technically advanced, formally intriguing, as well as aesthetically challenging. The designers' determination in searching for the creative proposals to incorporate reclaimed products is to: (1) overcome the users' negative perception of reintroduced pre-used building products, (2) stimulate positive experience of cultural continuity manifested by retained material substance, (3) contribute to the end-users' approval of alternative design proposals, 4) form the emotion-driven, intense, and long-lasting product attachment.

The two perspectives of substance and immaterial, referring to the material potential of pre-used building products and their intangible values influencing the users' reaction, are identified to analyse the design scheme's effectiveness regarding the extension of lifetime of building products' (Figure 2).

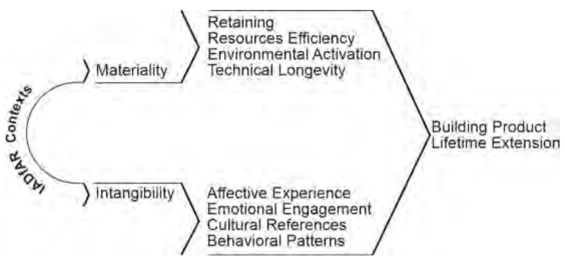

**Figure 2. The effectiveness of IADfAR: substance and immaterial contexts.**

## Design framework: materiality context

*Retaining*
This design framework embraces reintroducing of the reclaimed selected building products into the building fabric. They frequently display only relative obsolescence or apparent worthlessness, still proving their high utilitarian properties. Their disposal frequently comes about not due to factual deterioration in functionality or excessive physical damages but is the consequence of the process of complex demolition which entails the disposal of many of elements of a building, without prior assessment of general technical conditions of particular building products. The retention of reclaimed building products provides the preservation of their embodied energy, reduction in the amount of natural resources, prevention from the carbon emission, decrease in construction waste, as well as restraining from the energy-consuming recycling strategy alternatively undertaken.

*Resources Efficiency*
The design scheme accomplishes the eco-efficiency providing a method for recirculation and redistribution of resources. In particular, it complies with the sustainability-oriented demands for the "resourcefulness and restraint" (Walker, 2006, 81) in design. This strategy, applied to the architectural design of the interior components, assures their high environmental profile through the following: (1) Avoidance of significant reshaping or reprocessing of the pre-used building products, (2) Performing only essential interventions in the structure or surface of secondary products (e.g. removal of possibly toxic finishes, cleaning from dirt and residues), (3) Reduction in the amount of finishing materials.

The employment of the surprise as a design strategy (Ludden, Schifferstein & Hekkert, 2008) is a means to evoke the beneficial user-product interaction. IADfAR turns the occupants' attention to the effective usage of building materials and products in interiors by the inconsistencies in different aspects concerning the occurrence of interior components (e.g. specific setting of pre-used products, exploration of their tactual attributes), as a leading design method. The design techniques to rise the user's curiosity comprise the following: (1) Misleading associations (e.g. employment of building materials with properties inadequate to form certain shapes), (2) Functional assignments (e.g. exploration of physical properties of the recovered products to improve the quality parameters of indoor environment), (3) Processing techniques and range of their application (e.g. chopping or crushing to examine the function-related properties of products, while apparently deteriorating their physical condition).

*Environmental activation*

The pre-used building products acquired to form interior components perform as objects to fulfil the basic functions, as well as instruments of passive interior architectural design. Depending on the spatial layout, applied working techniques, as well as a creative exploration of the physical properties of building materials of the secondary building products, the interior components which accommodate these, act as the objects "environmentally activated" (Celadyn, 2018), and participate in adjustment of the indoor environment quality parameters (e.g. relative humidity of inner air, reverberation time, sound diffusion). This building materials' contribution to the improvement in quality of the indoor microclimate parameters indirectly influences the users' sensorial experience.

*Technical longevity*

The discussed design scheme respects the accumulative process of ageing in building products, accepts and articulates the signs of decay to protect them from disposal. It examines a creative approach to assimilate the marks of physical deterioration, malformations, discolorations, or other physical symptoms of time-related material destruction. This design approach, deliberately revealing the objects' imperfections or even slight damages, aims to slow down the potential removal or replacement of these parts or components. The application of design techniques (e.g. exposure of unfinished and imperfect surfaces of reclaimed products as a means to absorb the succeeding marks of usage) contributes to lengthen the usefulness of the secondary building products making constituent parts of interior components, as well as to extend the technical longevity of newly completed components.

## Design framework: intangibility context

*Affective experience*

Materials strengthen the design concept while offering opportunities for the users to interpret it and to express meaning (Celadyn, M. & Celadyn, W., 2021). IADfAR provides the users with affective experiences, driven by sensorial properties of building materials, particularly these attributes concerning visual and tactual aspects of the user-product interaction. The exploration of physical attributes of the acquired pre-used building products, and testing of the traditional building techniques to fulfil design requirements, intensify these experiences. This approach allows to examine comprehensively materials' sensorial attributes, which provide building products alone with a distinct meaning, as well as interior components they are intended to form. The experience of these compound products-interior components is mainly a human-product "non-instrumental interaction" (Desmet & Hekkert, 2007, p. 14). This kind of communication does not directly serve the function in operating a product, still it elicits the sensorial experience stimulated by perceived physical properties of the product (e.g. texture of building material).

Among factors influencing the experience is the physical context in which the user-product interaction takes place. The placement of pre-used building products in the inner spaces, creates a multilayered physical context thus, strengthening the possible affective experiences. Through the conscious stimulation of affective experiences based on the product-originated curiosity, inspiration, as well as fascination towards interior component, it's possible to provoke the multidimensional exploration of a product. This intensive user's involvement is the most desirable behavioral response, especially when followed by the arousal of the user-product attachment.

*Emotional engagement*

The meaningful properties of materials, adding the value to technical and functional characteristics, increase their role in terms of aesthetics for sustainability, while affecting the users-products engagement (Crippa et al., 2012). IADfAR affects the end-users' emotional involvement by exploring the characteristics of specific setting, as well as expressive properties of materials of pre-used building products. The gaining of emotional engagement through the broad inclusion of reclaimed products, depends on the purposefulness, meaning, expression, quality (Desmet, 2010) of building materials, as in the case of any product design. The design techniques applied (e.g. juxtaposition of porous and smooth surfaces, systemic reveal of roughness of finishing layers, exposure of objects' physical imperfections, presence of stains and fading) allow extensive display of materials' attributes in order to encourage the intuitive, emotional responses from the users.

The design strategy to strengthen and then extend in time the emotional attachment between the user and the product is an essence of Emotionally Durable Design (EDD) (Ceschin & Gaziulusoy, 2016). This consumer-product attachment is defined as a specific relationship developed based on the emotional ties between the user and a particular product (Schifferstein & Zwartkruis - Pelgrim, 2008) and remains outlined as a feasible sustainable design strategy (Page, 2014). IADfAR stimulates the users' emotional responses and contributes to the development of strong user-interior component affection, proposing the unpredicted, astonishing appearance of familiar building products to form the interior components. Making a more lasting the emotion-driven relationship between users and the secondary building products, continuing their technical life as constituent parts of interior components, is substantial for the effectiveness of the proposal.

### *Cultural references*

The cultural connotation of pre-used building materials (e.g. references to the continuing local building tradition, historical value of the locally developed manufacturing processes being preserved in the reclaimed building products), merged within the structure of interior components, adds meaning to their formal and functional attributes.

The cultural references of the secondary products, contribute to the emotional durability of interior components, as well as their composite substance-semantic content. The cultural connotation, marked in the structure of these compound products, appeal to the concept of the three levels of design (Norman, 2004). They encourage shifting from the visceral level of user's response to the product's occurrence, through the behavioural state, up to the reflective level of conscious interpretation of experienced emotions. The level of cognitive elaboration and arousal of a product's meaning, due to the perceptible connotation, is essential. This allows to override the occupant's well established attitudes towards the pre-used products' appearance (e.g. rejection of visible signs of wearing, negative reaction to the physical imperfections, concern about rough surfaces). It also refers to the value of the product in time-related perspective and helps in "linking the individual product experience to its societal, cultural, and historical context" (Schifferstein & Zwartkruis-Pelgrim, 2008, p. 3).

### *Behavioural patterns*

The recognition of the environmental association in the interior components by the users determine the successful built-up of the user-product connection. This is viable by the following: (1) broad exploration of specific mechanical working, (2) assembling techniques to implement the pre-used products into the structure of interior components in a creative way, (3) considering the physical and sensorial properties of materials. These issues are to stimulate the users' positive emotional experience that conditions the development of the product attachment. The latter elicits the users' more protective behavioural patterns toward the products causing this kind of interaction (Mugge, Schifferstein & Schoormans, 2006).

This engagement affects the rational and careful usage of objects, and their further systematic maintenance, thus indirectly responding to the issue of resources efficiency. Therefore, this interior architectural design scheme, emphasizing the environmental context in interior components development, impacts the users' habits and attitudes. It contributes to the Design for Sustainable Behaviour (DfSB) in its environmental dimension, while encouraging the users to adopt more environmentally sustainable patterns of the products' use, making the implementation of pre-used building products to form interior components, as an exemplary model.

## Conclusions

The Interior Architectural Design for Adaptive Reuse, examines the design method to minimise the negative environmental impact of building products, discussing the potential of the inter-setting transfer of pre-used building materials to form the selected constitutive interior components. This concept aims at the preventing the discarded building products from prematurely becoming demolition waste, while turning them into a valuable resource. This design scheme, assessed from the material and substantial perspectives, indicates its effectiveness. This is analysed with regard to the extension of the physical and emotional longevity of building products salvaged during demolition or refurbishment, as well as that of interior components, of which they are structural constituents. This design conceptual framework reveals to be inducive for the application of the circular perspective to the interior architectural design interventions.

# Developing Samples of Small-Scale Remanufacture from Pre-Consumer Textile Fallout

**Child, Emmeline**
a) University of Northampton
b) Chelsea School of Art and Design, UAL

**Keywords**: Remanufacture; Scaling; Fallout; Fashion; Upcycling.

**Abstract**: The context of this research is in the prolific levels of waste in the textile industry (WRAP, 2016). Less than 1% of material used to produce clothing is recycled into new clothing (Ellen Macarthur Foundation, 2021). Wasted material is also wasted money (Stahel, 2019) evidencing a sizable economic benefit to the industry to embed greater methods of remanufacture. By working with developed frameworks and garments from a textile manufacturing facility, the aim of this research is to understand if upcycling, utilising industry whole product fallout (seconds or production line errors) (Child, 2020) is possible.

It is estimated that approximately 10-20% of textiles are 'wasted' during garment manufacture (Lau, 2015). Manufacturers are currently bound by strict regulations imparted by the brands (Gunawardhana, 2016). This means that it is easier to incinerate fallout rather than deal with the complex issues around upcycling.

By reviewing samples from a manufacturing facility, the aim is to use the design-led insights to test if utilising whole product fallout is a viable resource for remanufacture in the future. The aim is to develop upcycling prototypes, to evidence the viability of using design as a solution to some pre-consumer factory fallout. This research will conclude by making suggestions for embedding design methods of remanufacture using fallout within scalable settings.

## Introduction

Demand for ever-cheaper production has pushed manufacturing further afield to developing countries (Ansett, 2007; Niinimäki *et al.,* 2020). The result of this is an unsustainable industry, where a holistic understanding of the supply chain has diminished, and issues of waste have become exasperated by the volumes of cheap products being produced (Niinimaki, 2013). These failings have led to complex issues arising around mass production and consumption, with waste being an increasing problem to deal with along each stage of the extended supply chain. Traditionally upcycling has been a micro-business model and unsuitable for companies wanting to scale up (Singh *et al.,* 2019). However, saturation point at both ends of the supply chains means that there is an abundance of resource that has the potential to be remanufactured, but currently, limited tools to support individuals on how to do this (Chapman, 2005).

Remanufacturing is a process of reinstating a discarded product back to its useful life, according to Lund (1996). Remanufacturing utilises existing material resource and therefore minimises the need for virgin material making it an excellent method to reduce waste (Krystofik *et al.,* 2015; Stahel, 2019). Stahel argues that remanufacture is more economically profitable, ecologically desirable, and currently the most advanced circular activity available (2019, p.26).

Despite pre- and post-consumer waste being different resources in the industry, from divergent waste chains, the methods in which the practice-led outcomes are developed draw little distinction from virgin or used material sources. There is a range of restrictions that the designer must address when working with these materials that, in some cases, can also present opportunities for unique design solutions (Keith & Silies, 2015). The pre-consumer waste being remanufactured as part of this research focuses on whole products and therefore is in garment form. As a result, the design techniques and processes informed by post-consumer waste (Child, 2016) has the potential to work with the increasing levels of virgin production falling out of the system (Child, 2020).

This research takes samples from a facility to test if scalable remanufacture solutions could be possible to add to the material lifetime, extending its potential in-use phase.

## Materials and Methods

A small product range of fallout samples were released from a manufacturing facility in Sri Lanka, selected as it is one of the leading sustainable facilities producing for many UK retailers.

Using the Design Framework for Upcycling (Figure 1), (Child, 2016), the process began by using design led strategies to respond to the garments given. For this test, garments were supplied by the manufacturing facility and were not predefined. The mixed fibre woven garments account for the biggest product fallout in this manufacturing facility and therefore validates the use of this resource (Child, 2020, Gunawardhana, 2016). Access to material on volume is key to ensure success when designing within these contexts and to facilitate upscaling. As the product is virgin, it ensures that the quality of the material is suitable for resale and minimises some of the barriers that can be found when working with post-consumer waste streams, allowing for a greater breadth of materials to be used. If this was implemented across other facilities, it is worth noting that different manufacturing sites have specific specialisms or product ranges of focus, which would result in a divergent base material to work with.

Observations will be made about the whole products utilised while enabling more generalised conclusions around the viability for remanufacture to increase the lifetime of the material.

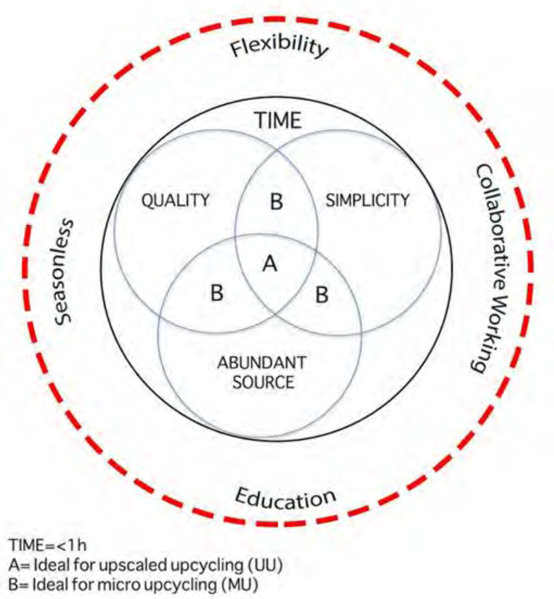

**Figure 1. Design Framework for Upcycling.**

*Process*

The garments were initially deconstructed then reconstructed, while being timed to gain an understanding of the time constraints, a key factor when considering scale. Figure 2 shows the first garment in its original form before the deconstruction process, showing multiple branding locations across the garment.

**Figure 2. Factory Fallout, Pre-Disassembly.**

The first process was to cut and unpick any branding from the material base (Figure 3) as garments must be completely clear to comply with the retailers' strict brand protection (Gunawardhana, 2016). This product line included branding on-seams as well as on the body of the garment, all of which needed to be removed before the base material could be reutilised. This threw up additional challenges as an unpicking process was required for the binding around the seams and is more time intensive than cutting alone. However, this process does not require any additional specialised areas or equipment and is not complicated as a process so facilitates scalable solutions. The process of deconstruction was timed as both the deconstruction and reconstruction elements need to be streamlined to create commercial, scalable outcomes.

**Figure 3. Factory Fallout, Pre-Disassembly**

Once the garments branding was removed, it was clear it would necessitate additional material from alternative garments to have enough base material left to create a garment of similar size and quality to follow the method of remanufacture. Therefore, it was essential to de-brand multiple garments to gain enough resource to work with (Figure 4). Due to the quantity of branding printed onto the fabric, it proved necessary to use two fallout products to make one completed garment (Figure 5).

**Figure 4. Garment 2, During Disassembly.**

**Figure 5. Remanufactured Top.**

Figure 6 shows the removed branding material from the four initial garments worked on within this pilot test. Although waste is still produced, it has significantly decreased from the original amount of fallout collected, reducing the quantity of virgin textiles being incinerated or landfilled.

**Figure 6. Removed Branding.**

The decision was made to reproduce a simple t-shirt that would be a similar product range to the original fallout garment, following the traditional remanufacture method where products serve the same function or end-use as the original (Den Hollander *et al.*, 2017; Dissanayake & Sinha, 2015; Hatcher *et al.,* 2013; Lund, 1984). It is important to adopt flexibility when working with this resource, and therefore mixing materials from alternative garments became a useful technique in creating a novel garment. The designer needs to be able to adapt to the different resource and respond to the available fallout to maximise the potential outputs. By working with multiple garments, the positioning of the branding was in different places allowing for greater streamlining when piecing back together. It was possible to utilise the top section of one garment and the bottom section of a different product style. This highlights the need to have a designer in this environment to respond to multiple product lines as they fallout the system, resulting in further efficiency gains (Von Weizsacker *et al.,* 1997).

Figure 5 shows the garment once remanufactured. The product is now void of any branding material as stipulated by the manufacturing facility. This allows prospective new markets to be sought for the product range or for existing brands to utilise this product as a subsidiary range within their collections. This has the potential to be utilised in both local and international markets, due to the commerciality of the product.

As garments are costed based on their time to manufacture, this investigation provides important information on whether this product would be financially viable to embed into the production line. Overall, the t-shirt took 8 minutes to deconstruct, with a further 12 minutes to remanufacture. Although this timing would differ to that in a factory setting, where individual workers would be allocated specific tasks to speed up the process, it allows us to identify that the deconstruction time almost significantly increases the overall production time of this garment. This would therefore almost double the unit costs in this setting. It is worth noting that the fallout material is already on site and cost neutral, therefore reducing some of the additional on costs. This cost implication is a consideration and could be a contributing factor as to why remanufacture in fashion is not currently more widespread.

Using the iterative practice, a second design was developed with mixed fibre woven jersey jogging bottoms. Again, like in the first process, it was necessary to remove all branding. Once this was completed, the same method was adopted to create a whole garment (Figure 7).

**Figure 7. Remanufactured Trousers.**

This shows that there are consistent barriers arising regardless of the product used. The fallout given for this test was also different colourways, and the aesthetic appeal of this will need consideration. This highlights the role of the designer in the process to make decisions related to commercial colour pairing. The colour of fabrics is an important consideration when designing a new product (Paras & Curteza, 2018), therefore, it may be necessary to produce a complementary colour chart to help manufacturers piece the material together in the manufacturing facility to allow for commercial taste.

This iteration was straightforward, branding was only on one leg, while it was more integral to the surface of the other garment. The time taken to deconstruct was only 4 minutes, with only another 7 minutes to piece back together. Resulting in similar time considerations to the first garment.

From these insights, a step-by-step framework was developed to support manufacturers wanting to implement similar processes within their chain (Figure 8). This considers the existing supply chain process with an additional 'novel' loop added.

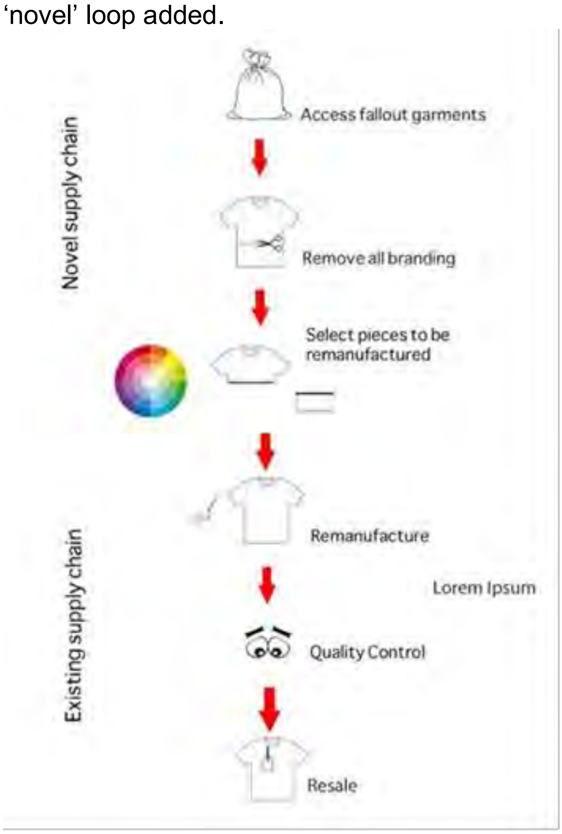

**Figure 8. Process Framework for Remanufacture.**

*Results*

From the original four garments selected, two garments were remanufactured. This reduced the original waste by up to 50% while creating novel garments suitable for re-sale from product fallout. This evidence the real reduction in waste, while extending virgin material lifetimes and cascading waste to landfills (Hall, 2021).

The garments through the process of remanufacture, took on a different design aesthetic to the original garments, reducing concerns around brand protection. This was realised by embedding the method of using two different fallout product ranges to make one (Figure 9). This aesthetic shift became an opportunity when making a case for commercialising this technique, as you can seek new commercial markets with this product without compromising the product aesthetic from the original garment and fashion brand.

Reviewing the quantities of product given by the manufacturer allowed a greater understanding of were some of the common placements of branding exist on the garments.

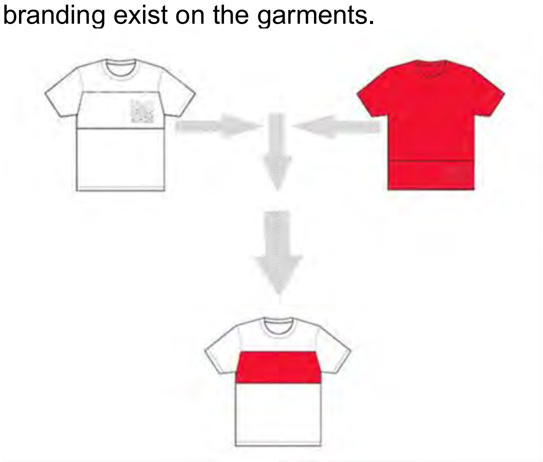

**Figure 9. Design Framework for Remanufacture.**

If this process was to take place within the manufacturing facility, there could be additional barriers and opportunities to consider, that would need further testing. Understanding how to intercept whole product on scale and develop multiple product lines will be key to oversee. Understanding how to bridge the gap between the designer and the manufacturer will also highlight design challenges when re-designing in response to product fallout. While the increased manufacturing costs will be a challenge to implement into the linear and LP lines when costings account for the primary incentive for manufacturers.

## Conclusions

From these samples, it can be concluded that remanufacture of fallout is possible; however, there are many barriers to overcome. Eliminating the logos/branding is time-intensive, meaning less time is available for remanufacture. This puts cost pressures on the product range and explains why incineration has been a key strategy to date. The time taken to manufacture is a consideration when working with factory fallout, therefore, simple design may be a crucial method to implement when developing this product range for upscaling.

Gaining access to the material resource was one of the most time-intensive and challenging aspects of this small product test and is one of the barriers to achieving success when working with this product resource. Greater transparency and accessibility is needed by brands to support the remanufacture of this product resource.
Significantly, the role of the designer is crucial at the product development stage and having a designer in-house in the manufacturing facility will enable flexibility in the decision-making process. This would support and eliminate barriers that arise from non-standard processes, such as using mixed colourways of multiple materials and working with smaller fabric pieces. Not having a trained designer in house is a potential barrier to success when working in an upscaled environment if adequate training is not supplied. However, utilising in-house designers may be a key strategy for manufacturing facilities to move forward, which would also create new roles in the industry. Importantly, this research has highlighted that to embed into a manufacturing facility, investment is needed to train the teams involved with the product range, and novel job roles may be required. Currently, without a market, there is resistance to invest in this area. Greater joined up thinking and collaborative working with brands and manufactures are needed to capitalise on this potential, while offering waste reductions overall.
This research has highlighted that the Design Framework (Figure 1) and Process Framework for Remanufacture (Figure 8) can be applied to different product types and works in the pre-consumer context. Future research will be necessary to identify if these design-led observations can work within the commercial supply chain. This will enable a better understanding of what additional developments are needed for the initial frameworks to embed this strategy for up-scaling.

This research has highlighted an area of waste that has had little focus to date. By raising fallout as an issue, further research can be carried out to understand better how best to capitalise on this resource to extend the material lifetime, while reducing the rate of usable waste going to landfill or incineration.

## Acknowledgments

Special thanks to the manufacturing facility for allowing access to the resource.

# Understanding product hibernation periods with children's products and exploring motivations for product care to encourage their reuse

**Yoon Jung Choi(a,b), Brook Kennedy(b)**
a) Royal College of Art, London, UK
b) Virginia Polytechnic Institute and State University, Virginia, USA

**Keywords**: Product hibernation; Children's products; Product care; Reuse; Circular economy.

**Abstract**: The phenomenon of product hibernation, namely the process by which end-of-use products are kept but no longer used is a common and significant barrier to prolonging product lifespans within a circular economy. Obsolete products challenge users' decision-making process for the after-use phase and are often discarded despite being perfectly functional. Especially in households with growing children, where children's products are outgrown but not discarded, product hibernation is the result. This paper presents the survey findings of 157 hibernating children's products, and interviews with ten families with growing children in the UK who have moved house, exploring product ownership, reasons for product hibernation, and the various barriers for their reuse. Understanding owners' product care motivation for re-recognizing their value and providing choices to reuse the children's products is vital to reduce product hibernation. Further, a workshop was conducted to explore the owners' reuse experience of with their children's products and the factors affecting their consistent caring process which aim to encourage people to reuse these products more. Through an idea generation process, nine influential factors were identified that suggest opportunities to change users' perception of the value of the end-of-use and care for these products. This paper makes an original contribution to product reuse knowledge with the development of a framework for understanding reuse motivations and barriers through the lens of care.

## Introduction

In households with growing children, children's products are often outgrown but not discarded, resulting in product hibernation that may encourage wasteful attitudes. According to the British Heart Foundation, 28% of parents throw away toys that are still in perfect condition, and as many as 47% admit that their children get tired of a new toy after just one week. Additionally, more than 183 million items of kids' clothing are thrown into landfills each year (Ellen MacArthur, 2017). The average young child needs new shoes every four months, leading to a rapid replacement cycle that sees Britons buying 80 million pairs of shoes per year, most of which end up in landfills (Berg & Magnus 2020).

A transformation of the children's product industry is urgently necessary. A transition to a circular economy will support to better capture the value of underutilised and landfilled children's product. The Circular Economy (CE) aims to reduce our impact on the planet by keeping products in circulation for as long as possible and out of landfills. It requires a systematic approach to maintain high quality products and materials. The closed-loop cycle with empowering circling longer through prolonging and reuse offers an alternative to selling significant numbers of low-cost products. In practice, this means exhausting every opportunity for reusing, re-purposing, and proving that it is possible to generate financial profit while respecting both the environment and society. One of the most environmentally friendly behaviours is to reuse the products you already own because it does not require raw material extraction or energy and water associated with new product manufacturing. As we are in the transitional stage to a CE, appropriate design approaches are needed to address people's sustainable behaviour in dealing with children's products, until a full circular system is established.

Care practices are an activity that aims to maintain value (Rodgers et al., 2019) and support caregivers (users in this case) to rediscover and re-recognize products' value. This research explores the drivers for reuse behaviour for product maintenance, focusing on key decision-making factors through the lens of care.

## Hibernating Products

"Hibernation, the dead storage periods when a product is still retained by users at its end-of-life" is a common important barrier to the circular economy (Wilson et al., 2016). We keep things we love because they add meaning to our lives; therefore, having an emotional attachment to objects is not always bad. However, in certain cases, people take no action when they are no longer needed, piling up objects at the back of the cupboard, as they still have emotional resonance, to be forgotten, or otherwise throwing them away although they are still perfectly functional (Botsman & Rogers, 2011). Hibernating products results in increasing people's wasteful attitudes. It is, therefore, crucial to understand the factors that inform the user (or owner) decision-making processes that result in hibernating products at end of use to overcome throw-away behavior and offer promising solution alternatives.

## Methods and procedure

*Survey*

In this study, a survey through a questionnaire was undertaken. In the first section, the research objectives and contexts are explained. The term 'end-of-use' object in this questionnaire refers to "objects that have ended their useful life, hence they are in a hibernation period" (Wilson et al., 2016). In the second section (1) participants were asked for their names; (2) participants' occupations were requested to provide collective and aggregate profiles that ensure that the participants were not taken from one sector. In the third section, participants were requested to answer whether they possessed hibernating or accumulated ~~objects~~ products at the end of use in their domestic environment. They were asked to list a maximum of three hibernating or accumulated products at end of use. The participants were recruited from primary school parent's groups via email communication.

*Interview*

The survey result provided an overview of the products in hibernation, however, to design a complete circular system it is important to understand the users' end- of-use phase and what is restricting users' further behavior. The semi-structured interviews were conducted with people who were facing a genuinely challenging moment. These were the people who were moving to a new house within a few weeks, and who had growing children. Ten series of interviews and five casual conversations were conducted over a ten-month period. The interview participants were selected from the survey participants. The casual conversation was carried out via phone calls after a certain period of time had elapsed, when the interviewees had moved to new places. They were asked to list the objects which had been thrown away of the three they had listed, or other objects, if necessary.

By following a thematic coding analysis approach, each participant's insight was written on an individual note, in the order that the participants mentioned the barriers (or motivations). The frequency of the words used by the participants and the tone of voice were important measuring tools to understand the users' relationship with hibernating or accumulated objects at end-of-use.

*Workshop*

Understanding owners' product care motivations for re-recognizing their value and providing choices to reuse the children's products are vital to reduce product hibernation. Therefore, a workshop session was conducted to explore the owner's reuse experience of their children's products and the factors affecting their consistent caring process which aim to encourage people to reuse these products more. The workshop enables the researcher to observe the participants' experience and collect data on the spot. Participants were asked to bring in their children's products in hibernation to the workshops. Additionally, they brought in children's products that had been used since their children were babies to analyze the factors affecting their consistent caring process. They were then asked to generate ideas create value for reuse. The idea generation session in the workshop lasted for two hours: ten minutes for each idea exercise on each influential factor that came out from the previous interview. Additionally, the motivations for product reuse were further discussed.

## Result

Three studies were conducted in this research to explore users' relationship with hibernating children's products.

### *Product in hibernation*

Among the 157 objects, children's toys, followed by clothing and shoes, and stationary were the most common hibernating or accumulated objects at end-of- use in the home although they are no longer needed, followed by books and furniture, and electronic related items.

### *Lingering attachment*

The survey and interview results provided an overview of people's behavioral barriers to reuse for children's products. Table 1 shows the classification of users' relationships with hibernating or accumulated objects at end of use into three different types. These are: 'users have lingering affection', 'users have lingering regret', and 'users have lingering responsibility'. A) relationship where 'users have lingering affection' toward the object. This involves the emotional aspect of attachment. B) A relationship where 'users have lingering regret' towards the object. This does not involve so much emotional attachment but involves a practical aspect of attachment. C) A relationship where 'users have lingering responsibility' towards the object.
The interview with people who had moved to new homes that has resulted in a C-type relationship does not involve so much attachment; instead, it has a high chance of disposal. Considering the responses from A2, A3, A4, and A5, there was a lingering emotional connection to those objects, and they were keeping them for a mostly unknown future for no particular reason. Users tried to avoid throwing them away but couldn't find a place where they would be needed. This indicates that objects in the C relationship require a design approach to increase the emotional connection or other external factors to reduce hibernation periods but to be taken care of. The objects in the B relationship were reluctantly thrown away except pharmaceutical and cosmetic products. When users realized their financial value, they tended to keep them for a possible next opportunity that might arise.

| Types of Object-User Relations | Recorded objects | Detailed background |
|---|---|---|
| A. Users have lingering affection | Some gifted items (e.g. inexpensive gift from their children)<br><br>A folding table, duvet, musical instrument, board game, children's painting cards received from their children<br><br>Chocolate packaging, Jacket, Kids' pair of boots. | It was an unwanted gift and the participant kept it because owner appreciate the person who gave them.<br><br>It contained memories and history of their children and family.<br><br>Participants kept them for years even though they were not used because they liked the designs of the product. |
| B. Users have lingering regret | Pharmaceutical products<br>Cosmetic products<br>Old Mobile Phones<br>Out dated electronics<br>Gaming cables<br>Kids toy<br>Cardboard boxes<br>A pair of running shoes<br>Sports equipment | They were kept at the back of their drawer (or fridge) because they had forgotten them, or just in case they might need them in the future although the use-by date had expired.<br><br>It was kept because I (or my children) might need it later. Sometimes they forgot they possessed the objects.<br><br>The functionality aspect was an important reason to keep it. |
| C. Users have lingering responsibility | Tent kit, Children's clothing, and socks, Books, Children's car seat, Children's kitchen Utensils, Children's bed frames, and mattresses<br>Children's furniture (desk, and bookshelf)<br><br>Children's hair accessories<br>Children's potty<br>A pair of running shoes<br>Underwear<br>Children's wetsuits | They were kept because the participants felt uncomfortable throwing them away due to the good quality of the objects and environmental concerns.<br><br>Participants don't know how to find /haven't found another user. It takes time and is not easy to find someone to giveaway due to size, and weight.<br><br>It takes up a lot of space. Difficulty of Disassembly<br><br>Fixed idea of inability to find new recipients.<br><br>Participants think it may be difficult to give it to a new recipient for reasons of hygiene. |

**Table 1. Analysis of emotional factors at play for users (or owners) towards hibernating products.**

| Influential Factors | Comments |
|---|---|
| Durability | The quality of materials, particularly plastic, has had some influence on the lack of use up until this point, as plastic toys fail to offer long-term satisfaction.<br><br>it is robust, and despite being plastic, it has held up and the color has not degraded at all.<br><br>Solid Construction. |
| Adaptability in growth of children | Updating the software is not a straightforward task, and the small screen on my son's Nintendo device has become less practical as he's grown older. He uses his own laptop to play game.<br><br>My son used to enjoy playing with his fire track plastic toy, it is no longer suitable for his current age and interests. It's not useful but I am keeping I might need it later. |
| Adaptability in the different context | Sports-related products, such as footballs, are often used for extended periods of time and can be utilized in various contexts beyond their intended sport. |
| Modularity | The plates and cutlery for children are typically designed with small sizes and specific graphics that are appealing to kids, such as the popular "Paw Patrol" characters. However, my kids have now outgrown these items and are no longer interested in using them.<br><br>Make clothing transformable.<br><br>I like my spiderman figure, it can move its arms, legs, and neck for different poses |
| Expandability | My children have outgrown their clothing, shoes, blankets, and other apparel, rendering them unusable. Those products can only be used for a certain amount of time. |
| Scalability | Not a particularly extendable structure but the product that I can adjust the size will be great. |
| Rewarding experience | Providing various rewards at different points is important. Rubik's cube is a timeless toy that provides me with a rewarding experience every time I play. |
| Gender neutral | Toys, soft toys, and games are often designed with gender-specific colours, such as blue and dark shades for boys and brighter colours like red, pink, and purple for girls. However, my kids are outgrown and not inclined to use products that are marketed in this way.<br>I was trying to give away the toy, and then the mom said it was too boyish, her daughter might not like it. |
| Aging gracefully | Make product repairable and cleanable will create attachment. |

**Table 2. Influential factors suggest opportunities to change users' perception of the value of the end-of-use and care for reuse.**

## *Design Considerations for Children's product care and reuse*

Focusing on the objects in the B and C relationship, a workshop was conducted to better understand the way to recapture value from the users. Table 2 summarizes the discussion that came out through the workshop session, which is organized by the potentially influential factors that suggest opportunities to change users' perception of the value of the end-of-use and care for the products to reuse. Nine relevant factors were identified to be applied in the children's product design process, except the gender-neutral factor requires further discussion. The result of applying gender-neutral factors in the design of products could limit consumer choices. More than half of the workshop participants faced challenging moments in exploring ideas. P4 mentioned, if children's products are not designed for a specific gender, there will be a slightly better chance that they will be reused and shared. However, another participant suggested that consumers should have the option to select gender-oriented children's products rather than having no choice at all.

Forty-five concepts were generated using the factors driven by the findings from the interviews and literature review. Figure 1 shows some of the participants' ideas that came out through the workshop session for redesigning products in hibernation. A relationship among these factors was observed that will lead to the theoretical construction of the children's product care for reuse motivation model.

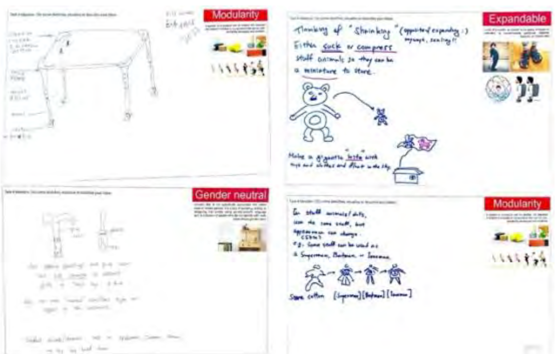

**Figure 1. A selection of ideas from the workshop.**

## Discussion

In order to successfully transition to the circular economy, designers are required to consider the result of hibernating or accumulated objects at end of use in an effort to prevent valuable resources from being thrown away. The product that is designed to be consistently cared for offers the ability to recreate the value of objects, reduce product hibernation periods, and be a part of a circular system.

Children's products that contain lingering affection were not considered in this research. In many cases, owners keep them in a special box or find a secure place where they can give away their objects that they still have a lingering affection for, so there is less chance they will be thrown away. The aim of this research was to explore the ways to recapture the value of products in hibernation and thereby extend the lifespan of children's products which have a high degree of lingering responsibility and lingering regret. The products in those products categories have the potential to increase product affection from users and extend product longevity through new design opportunities if there were available options or interventions for the user to recapture their reuse. The subsequent participatory workshop provided an opportunity to mediate the conversation, reminding participants about products in hibernation kept in their drawers or cupboards and allowed participants to reconsider further action in their reuse.

Although nine relevant factors have been identified during the workshop, adaptability factors tend to overlap with other factors such as modularity, expandability, and scalability. Adaptability was defined as the ability of an individual, system, or product to adjust and respond effectively to changing circumstances, environments, or requirements, which potentially could be the overarching factor that embraces modularity, expandability and scalability.

Having gender-specific toys may have less chance of being passed down or reused within the household, which can affect product longevity as it may not appeal to or be used by children of the opposite gender in the household. Additionally, keeping a product in a clean condition might also provide an opportunity for it to be cared for and reused. However, those factors clearly needs further research. Integrating such design considerations in the design process would raise designers' awareness of environmental and social problems, and would empower users to self-care, self-reuse, and self-upcycle their existing products. Maintenance tools or service should be made widely available in the market, in order to encourage consumers to provide consistent care to their products to further encourage business potential associated with prolonging product lifespans.

## Conclusions

Shifting towards a circular economy is one proposed solution, in which products are used and their value is recovered for as long as possible in a closed-loop system. Designing products for reuse behavior in the children's product category can empower the inner circle of the economy diagram by maximizing the number of cycles. Those behaviors are one of these closed loops that can be practiced by product manufacturers and users. It is vital to understand users' reasons for keeping products in hibernation and motivations related to their reuse to encourage them to care for the products more. This paper makes an original contribution to design research knowledge by identifying new motivational factors related to reuse behaviors, particularly for children's product longevity through the lens of care.

## Acknowledgments

The authors would like to thank the survey and interview participants. Thanks, also, to the workshop participants for sharing their products in hibernation thoughts and contributions to this project.

# Measuring long-term perceived quality in sports t-shirts: A comparison of two study designs

**Lars Claussen[a], Alex Lloyd[a], Daniel Ruiz[b], George Havenith[a]**
a) Environmental Ergonomics Research Centre, Loughborough School of Design and Creative Arts, Loughborough University, Loughborough, UK
b) adidas Innovation, adidas AG, Herzogenaurach, Germany

**Keywords**: Longevity; Testing; Quality; Perception; Sports clothing.

**Abstract**: This study aims to close the data gap on the long-term post-purchase garment quality for virgin and recycled polyester sports t-shirts. Long-term overall and perceived quality was assessed through both a real-life year-long wear trial as well as in a laboratory-based, in-store scenario, after repeated washing. Three research questions were addressed: 1) Does the quality perception of virgin and recycled polyester sports t-shirts change with prolonged wear and repeated washing? 2) Is there a difference in the perception of t-shirt quality between a real-life wear test and a laboratory-based, in-store scenario after repeated washing? 3) Does the use of different types of recycled and virgin polyester affect the quality perception of sports t-shirts? The quality ratings obtained from the two study designs showed that polyester sports t-shirts were of consistent quality over a one-year wear period and up to 52 wash cycles. Significant differences in the quality rating between the study designs were found only for virgin polyester sports t-shirts. The more pronounced use of tactile cues in the in-store scenario is one explanation for the differences in quality ratings between the two study designs. There was no difference in quality ratings between virgin and recycled polyester sports t-shirts collected during the wear trial, and recycled polyester sports t-shirts performed even better in the in-store scenario after repeated washing.

## Introduction

As a large contributor to environmental pollution, the sports apparel industry is transforming towards greater sustainability and circularity (Niinimäki et al., 2020). Extending the lifespan of garments and switching to more sustainable/recycled fibres are among the most effective ways of reducing the industry's environmental impact (ECOS, 2021; United Nations Climate Change, 2021; Wiedemann et al., 2021; WRAP, 2017). These suggestions are also increasingly adopted in policies. The EU textile strategy, for example, has the vision that by 2030 "all textile products placed on the EU market are durable, […], to a great extent made of recycled fibres, […]."(Directorate General for Environment, 2022). Extending garment lifespan and switching to more recycled fibres raises additional questions for the apparel industry, including how best to objectively assess clothing longevity and to what extent recycled fibres can influence this longevity.

Many textile testing methods exist that can indicate quality issues in garments. However, these tests only provide a snapshot of the current quality of the textile and, particularly for functional garments such as sportswear, it is difficult to relate the test outcomes to the quality perceived by the user, which ultimately determines the lifespan of the garment (Claussen et al., 2021; Connor-Crabb & Rigby, 2019). Repeated washing is often used to simulate the ageing of clothing (Benkirane et al., 2019; Claxton et al., 2015; Cooper et al., 2014; Heller et al., 2023). Whether repeated washing can replicate the ageing process of a textile during actual wear has not yet been validated. Previous studies have not been successful in conducting a long-term wear trial with a sufficient number of participants to compare repeated washing and real-life wear (Claxton et al., 2015).

Because of its functionality, polyester is the preferred raw material for sportswear. The switch from virgin polyester to mechanically recycled polyester can potentially reduce greenhouse gas emissions (United Nations Climate Change, 2021). However, several studies have shown that quality-critical material properties such as tensile strength of recycled polyester are lower than those of virgin polyester, and perception-based studies have shown scepticism about the quality of recycled clothing (Botwinick & Lu, 2022; López et al., 2014; Majumdar et al., 2020; Wagner & Heinzel, 2020). Both can potentially affect the longevity of recycled polyester sportswear. Whether there is a difference in quality perception between market-ready virgin and recycled polyester sportswear in long-term use has not yet been investigated.

To further knowledge on these issues, the following research questions are addressed in this study:

1) Does the quality perception of virgin and recycled polyester sports t-shirts change with prolonged real-life wear and repeated washing?
2) Is there a difference in the perception of t-shirt quality between a real-life wear test and a laboratory-based, in-store scenario after repeated washing?
3) Does the use of virgin polyester, mechanically recycled polyester, and mechanically recycled polyester that contains ocean plastics affect the quality perception of sports t-shirts?

## Method

The present study compares the long-term overall and perceived quality of recycled and virgin polyester sports t-shirts assessed within two study designs. Study design one assesses quality perception during actual use via a wear trial, and study design two assesses quality in a laboratory-based, in-store scenario after repeated washing.

Participants rated the overall quality on a seven-point Likert scale (low quality – high quality) (Oliver, 2015). Perceived quality for a wide range of attributes was calculated as the difference between participants' expectations of the performance of an excellent sports t-shirt before the experiments and their perception of the performance during the experiments (Abraham-Murali & Littrell, 1995; Parasuraman et al., 1988, 2002). For the expectations and performance ratings, participants were presented with statements about attributes of sports t-shirts. Participants were asked to use a seven-point Likert scale (strongly disagree – strongly agree) to indicate the extent to which an excellent t-shirt (expectations rating) and the actual t-shirts (performance rating) would possess these attributes. Nine attributes were selected from previous sports garment quality studies: 'Longevity', 'Workmanship', 'The ability to keep the wearer dry and at a pleasant temperature', 'Support in achieving higher athletic performance', 'Comfort', 'Fit', 'Look', 'Odour' and 'Hand feel' (Claussen et al., 2021). To test for differences in overall and perceived quality between time points/wash cycles, study designs, and polyester types, a Kruskal-Wallis test (overall quality rating) and a one-way ANOVA (perceived quality rating) were performed with a significance threshold of $p < .05$.

### *Materials*

A major sports clothing company supplied t-shirts made from three different polyester types: 1) virgin polyester (Virgin PET); 2) mechanically recycled polyester (Rec. PET); and 3) mechanically recycled polyester that contains ocean plastics (mainly PET bottles from beaches and coastal communities before reaching the ocean) (Ocean PET). Design, fabric structure and yarn fineness of the t-shirts were matched to ensure that any differences in perceived quality could be as much as possibly attributed to the type of polyester used, although variations in unknown parameters cannot be excluded due to the complexity of the textile chain. Small logos in different colours were printed on the t-shirts to differentiate them, but participants were blinded to the meaning of this difference. The t-shirts were each produced in a men's and women's cut and available in the sizes S, M, and L.

**Figure 1. T-shirts used displayed in men's cut.**

### *Study design 1: Wear trial*

This study presents twelve months of data from an ongoing wear trial that began in February 2022. Demographic and performance expectations were collected from a diverse sample of 244 participants who enrolled for the study. Each participant was given two of the three t-shirt types to ensure frequent use of the t-shirts. Participants were asked to wear one of the two t-shirts every month, alternating between the two. To ensure that all garments were tested simultaneously, half of the participants in a t-shirt combination group started with one t-shirt, and the other half of the group started with the other t-shirt. Participants were expected to wear and wash the t-shirts at least once a week. An online questionnaire on quality perception and the participant's t-shirt use and care behaviour was sent out every two months.

### *Study design 2: In-store scenario*
To replicate the real-life use of t-shirts, a repeated wash cycle test was performed according to ISO 6330:2012 (washing machine type A, procedure no. 4N, reference detergent 1, line drying) (British Standards Institution, 2021). Quality perception tests were carried out after 0, 26, and 52 wash cycles, representing a new t-shirt and approximately the times of wear at 6 and 12 months during the wear trial. 52 wash cycles correspond to literature recommendations for the target lifetime of a 'long-lasting' t-shirt (Claxton et al., 2015; Cooper et al., 2014; ECOS, 2021). A sample of 40 participants was invited to attend three sessions in a shop-like laboratory environment. The three types of polyester t-shirts, with the same number of wash cycles, were each tested in one session, and the order of the sessions was randomised. The participants were informed of the purpose of the study but were blinded to the number of wash cycles. At the beginning of the first session, the expectations rating was performed. During the sessions, the participants were given time to wear and familiarise themselves with the t-shirts and were then asked to rate the overall quality and attribute performance of the t-shirts.

### *Sample*
Loughborough University's Human Participants sub-committee granted ethical approval for the studies (Project ID: 5834 and Project ID: 10435), and participants gave written informed consent.

| Category | Wear trial ($n_{start}$=244) | Repeated wash cycle test (n=40) |
|---|---|---|
| Sex | | |
| Male | 122 | 15 |
| Female | 122 | 25 |

| T-shirt size | | |
| S | 72 | 25 |
| M | 91 | 15 |
| L | 81 | - |

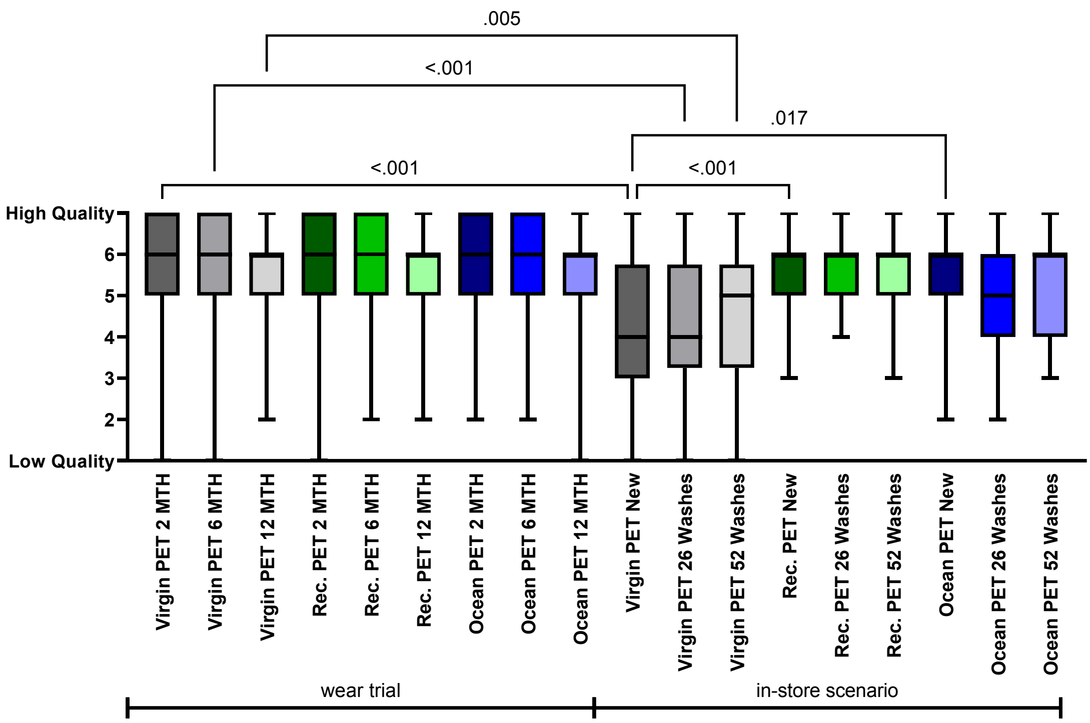
**Table 1. Demographics of samples.**

## Results
Both overall and perceived quality ratings of all three polyester t-shirts remained consistent over one year of wear and up to 52 wash cycles. No significant differences in quality perception were found between the different time points or wash cycles (Figure 2 and 3).

Significant differences in quality perception between the two study designs were found only for the virgin polyester t-shirts, which were rated significantly lower in the in-store scenario. The perceived quality rating varied between the two study designs for the attributes 'The ability to keep the wearer dry and at a pleasant temperature', 'Support in achieving higher athletic performance', 'Comfort', and 'Hand feel'. These differences were more frequent for the conditions 2-months wear and new (Figure 3).

While participants could not perceive any difference in overall or perceived quality between the different types of polyester t-shirts during actual wear, differences between the three types of t-shirts were perceived during the in-store scenario after repeated washing. In the in-store scenario, the unwashed virgin polyester t-shirts had a significantly lower overall quality rating than the mechanically recycled polyester t-shirts and the mechanically recycled t-shirts containing ocean plastic. There was no difference between the two recycled polyester t-shirts. It was interesting to note that in the perceived quality ratings, the differences between the materials were again apparent for the attributes ‘Ability to keep the wearer dry and at a comfortable temperature’, ‘Support for increased athletic performance’, ‘Comfort’ and ‘Hand feel’. Virgin polyester was rated significantly lower for these attributes than the other two polyester types. For ‘Ability to keep the wearer dry and at a comfortable temperature’ and ‘Support in achieving higher athletic performance’, the significant difference was only present for the unwashed t-shirts. Differences between virgin polyester and the other two types of polyester were found for ‘Comfort’ and ‘Hand feel’ for all washing conditions (Figure 3).

**Overall quality rating**



Number of responses:

$n_{2\ MTH} = 230$
$n_{6\ MTH} = 214$
$n_{12\ MTH} = 148$

Use and care:

## Discussion

It is often argued that a decline in garment quality has led to shorter garment lifespans, and the apparel industry is being challenged to change its design, production and testing practices to promote quality garments compatible with extended garment use and reuse (Aakko & Niinimäki, 2022; Piippo et al., 2022; Sahimaa et al., 2023). However, there is limited data on garment quality, particularly on the long-term quality of garments after purchase (Vesterinen & Syrjälä, 2022). The present study therefore examines the long-term quality of polyester sports t-shirts. The data demonstrates that for basic polyester sports t-shirts, quality perceptions remained consistent during a year-long wear trial and after up to 52 cycles of repeated washing, suggesting that the t-shirts are long-lasting. The t-shirts used represent basic polyester sports t-shirts, which suggests that this apparel category is likely less susceptible to durability issues.

To the authors' knowledge, this is the first study to provide data on garment quality perception during a year of actual wear ageing (wear trial) and to compare this with washing-induced ageing (in-store scenario). There were significant differences between the two study designs' quality ratings for the virgin polyester t-shirts, but not for the two types of recycled polyester t-shirts. Where there were significant differences, the ratings were lower in the in-store scenario. The fact that there were significant differences only for the virgin polyester t-shirts shows that the stimulus is a crucial factor in testing whether repeated washing can replicate extended wear. This highlights the difficulty of finding a method or general guidelines for measuring the longevity of garments made from different materials and for different use cases (Cooper et al., 2014). The lower ratings in the in-store scenario may have different causes. Based on observations of the in-store scenario, participants seemed to be more eager to find quality issues in the t-shirts than they would be in a real-life scenario. Differences in perceived quality ratings were only found for the attributes' Ability to keep wearer dry and at a comfortable temperature', 'Support for increased athletic performance', 'Comfort' and 'Hand feel'. In a scenario where participants interact with the t-shirts mainly by touching and trying them on, it makes sense that the hand feel rating is more central to the quality rating. Previous studies have shown that different interaction scenarios (touching, wearing, exercising in) can influence the tactile perception of textiles (Wilfling et al., 2023). The participants in this scenario did not do any exercise, they just tried on and touched the t-shirts, however they rated the attributes 'Ability to keep wearer dry and at a comfortable temperature', 'Support for increased athletic performance', and 'Comfort' significantly lower than the participants in the wear trial where exercise was involved. Clothing comfort is a multidimensional concept that includes physiological comfort, sensorial/tactile comfort, and psychological comfort and studies investigating the key factors in sports clothing comfort at different times/phases of exercise suggest that texture (roughness - smoothness) is the best determinant of comfort up to the first 10 minutes of treadmill running and during the rest and walking phases (Jiang et al., 2022; Raccuglia et al., 2018; Slater, 1985). Based on the multidimensionality and reciprocity of the clothing comfort concept, it is hypothesised that during the in-store scenario, participants will make assumptions about physiological comfort ('Ability to keep wearer dry and at a comfortable temperature'), psychological comfort ('Support for increased athletic performance') and overall comfort based on sensory/tactile comfort, about which participants in the scenario have more information. Qualitative feedback from the participants supports this hypothesis.

This hypothesis is also a possible explanation for the differences in the quality rating between the virgin polyester t-shirts and the two types of recycled polyester t-shirts during the in-store scenario. Objective measurements of the tactile properties of the t-shirts in the different washing conditions support this postulation. Differences in roughness between the t-shirt types were found, which were greatest in the unwashed condition (Claussen et al., 2022). That no differences between the virgin and recycled polyester types in quality perception were present during actual use, and that this differed from the in-store scenario, is an important finding which could assist in removing consumers and industry associated barriers to the use of recycled polyester (Botwinick & Lu, 2022; Wagner & Heinzel, 2020).

## Conclusions

Quality ratings of virgin and recycled polyester sports t-shirts obtained from a year-long wear trial and in-store scenario after repeated washing showed:

1) Contrary to popular belief, polyester sports t-shirts showed consistent quality over a year of wear and up to 52 wash cycles.
2) Significant differences between study designs were found only for virgin polyester sports t-shirts, suggesting tactile perception plays a greater role in perceived quality in an in-store scenario compared with actual wear.
3) Doubts about the quality of recycled polyester are not supported by the present data. There was no observed difference in the quality rating between virgin and recycled polyester sports t-shirts in actual use, and recycled polyester sports t-shirts performed even better in an in-store scenario.

# Durable Apparel in the Circular Economy: Exploring the effect of post-industrial material waste on garment lifetimes

**Claxton, S.**[(a)]
a) Nottingham Trent University, Nottingham, United Kingdom.

**Keywords**: Circular apparel and textiles; Post-industrial apparel waste; Clothing durability; Design for durability; Circular supply chain.

**Abstract**: A key principle within a circular fashion system is to extend garment lifetimes by increasing durability, thereby reducing consumption, and improving resource efficiency (Ellen MacArthur Foundation, 2017; Bocken et al, 2016). Durability is now an established concept within sustainable apparel, with research informing best practice principles for design and product development (Cooper et al, 2014). Sustainable design should be a strategic process, incorporating the integrated systems of manufacturing, distribution, retail, and consumption (Ceschin and Gaziulusoy, 2016), seeking to minimise waste and other environmental impacts at all stages of the product lifecycle (Vinhod et al, 2011). Nonetheless, problems occurring during the manufacture and supply of apparel designed to be durable can lead to material waste generation, thereby undermining any potential improvements in resource efficiency (Claxton et al, 2017). This paper uses a qualitative multiple case study approach to explore retailer and supplier perspectives of the nature and management of post-industrial material waste problems of durable apparel, and assess their effect on garment durability claims. The findings demonstrate that the garment lifetime can be compromised by material waste arising from inefficiencies and a lack of transparency within production process management. The paper concludes that retailers aiming to demonstrate circularity by producing durable apparel should review the relationship between durability and sustainability performance outcomes, where waste is viewed as an environmental, as well as a financial impact. Problems should be effectively managed to prevent material waste and a reduction in garment lifetimes, and solutions must be holistically applied, ensuring that all stages of the supply chain are included.

## Introduction

Durable apparel design seeks to reduce the need for consumers to replace garments that have failed prematurely, thereby reducing production volumes and the associated post-consumer waste (Ellen MacArthur Foundation, 2017). Indeed, extending the active life of 50% of UK clothing by nine months would reduce the annual carbon, water, and waste footprints by an estimated 20-30% each (WRAP 2017). Circular textiles and apparel literature tends to depict the lifecycle of a durable garment in a singular dimension, moving through potential cycles of manufacture, use and ownership within circular business models or CBMs (Pal et al, 2019). However material waste in the form of yarn, fabric and garments can be created at every stage of the upstream supply chain during manufacture, and also during the storage, transport and retail stages of the product lifecycle where garments may be found to be faulty, and customer returns or poor sales can lead to the disposal of wearable garments (Reverse Resources, 2017). The resource efficiency benefits claimed for durable apparel may therefore be undermined and the waste unaccounted for in apparel retailers' sustainability reporting (Akter et al, 2022). This study investigates the factors leading to post-industrial material waste within the apparel supply chain. By using a qualitative approach, the research aims to demonstrates a deeper understanding of the potential commercial and operational challenges of managing and addressing potential waste problems that could undermine a circular apparel model based on durability.

## Literature Review

### *Durability as a circular design principle.*

Improving apparel durability has been proposed a sustainable design approach as garments that last longer can theoretically reduce overall consumption, the associated environmental impacts of production, and post-consumer waste (Laitala et al., 2015). Advocates of the circular economy propose that the entire garment lifecycle should be considered, identifying opportunities to improve resource efficiency, reduce waste, and minimise damage to the environment at each stage (Ellen MacArthur Foundation, 2017). In the circular model, durable apparel is depicted within a system of multiple cycles of production and consumption, demonstrating its potential to retain and create value across different CBMs such as resale and rental (Pal et al, 2019). Physical durability can be enhanced by using fabrics and sewing methods that are more hardwearing, reducing the risk of garment failure (Cooper and Claxton, 2022), whereas emotional durability refers to the consumer's attachment to, and enjoyment of wearing the product that keeps it in use for longer (Chapman, 2015). Consumers already demand durable apparel in functional garments and classic wardrobe staples such as jeans and basic t-shirts (Fisher et al, 2008) and are more likely to wear a garment for longer if it continues to fit them well, feels comfortable and looks good; therefore good practice in emotionally durable design for classic apparel tends to incorporate ongoing improvement of body fit, overall design aesthetics and comfort (Cooper et al, 2016).

## *Factors leading to post-industrial apparel waste*

Apparel retailers normally outsource manufacturing to external suppliers, passing over control for volume production once a new style has been developed and approved (Shen and Chen, 2018). Factories follow routine quality assurance (QA) procedures to ensure that garments meet the specified aesthetic, physical performance and safety standards established at the design stage, and quality control (QC) practices monitor the consistency of the product as it progresses through production (Keiser and Garner, 2017). Textile and apparel manufacturers can apply risk assessment and lean manufacturing principles to optimize production efficiencies and reduce costs, as well as contribute towards sustainability by minimising waste However, materials, components and garments tested and found to be non-compliant may be rejected and potentially wasted if the problem cannot be rectified (Cooper et al, 2016; Vinodh et al, 2011). Furthermore, the transparency of post-industrial waste generation can be obscured by operational inefficiencies within globally fragmented supply chains, making it more difficult to share data and knowledge between the buying company and suppliers (Aage and Belussi, 2008). Influence over upstream suppliers can be weak, sometimes resulting in sub-standard materials and garments being hidden (for example in the practice of non-disclosed production sub-contracting), and the requirements for increased speed and flexibility of supply can lead to inadequate product risk assessment (Shen and Chen, 2018). As a result, clothing retailers and suppliers can encounter problems both during and after production that create waste and / or shorten the overall product lifetime (Claxton et al, 2017). Examples include defective materials and garments caused by poor process and inventory management; fibre, yarn and fabric waste generated during manufacturing; and surplus materials or dead stock caused by overproduction, late deliveries and inaccurate demand forecasting (see figure 1). Current post-industrial waste volumes are significant, with up to 25%-30% of the original fibre estimated as being wasted throughout the apparel supply chain, and less than 1% of raw materials being fully recycled as a closed loop process (Reverse Resources, 2017).

**Figure 1. Simplified apparel supply chain model with examples of material waste at each stage. Adapted from Reverse Resources, 2017.**

The effective resolution of waste issues requires negotiation between buyers and suppliers to establish responsibility and agree action to be taken (Cooper et al, 2016). As waste avoidance has a financial benefit, cost recovery is commonly prioritised in resolving waste problems rather than sustainability; this includes applying financial penalties to suppliers of faulty goods (Shen and Chen, 2018) and finding other markets or applications for substandard or surplus materials and products (Akter, 2022). However, the overall waste generated by producing a specific apparel style in volume within a globally widespread supply chain is difficult to measure as the retailer may only be involved in resolving issues created in the first or second tier of supply representing garment and fabric production (Reverse Resources, 2017). Curwen et al (2012) propose that a company mandate for sustainability, shared values between retailers and suppliers, and more effective and transparent knowledge exchange is needed to address these challenges, however the greater power of the retailer in supplier relations can lead to a lack of trust and transparency on both sides (Talay et al., 2022). To date, initiatives to address post-industrial waste have been limited by a lack of transparent data, and the low priority of waste within sustainability reporting, meaning that the journey and eventual destination of wasted material or product is often unknown (Reverse Resources, 2017).

### *Apparel durability and waste within the circular model*

Apparel retailers are now piloting CBMs to assess the economic and practical viability at scale (BSR, 2021), although infrastructural and cultural barriers limit consumer engagement (Camacho-Otero et.al., 2018). Nonetheless, many retailers have started to incorporate circular principles such as durability and recyclability into apparel design to prepare for a future circular model that may be more formally regulated through legislation (Gueye, 2021; European Commission, 2022). Measuring a product's environmental impacts can inform circular design approaches, and lifecycle analysis (LCA) frameworks can be used to map, measure, and address the associated water use, greenhouse gas emissions, chemical emissions, and energy consumption

(Munasinghe et al., 2021). However, apparel durability can be measured through physical testing regimes, but is not commonly incorporated into LCA frameworks that predict environmental impacts at the design stage (Kozar and Hiller-Connell, 2015). Moreover, even if a product has been designed to be durable, the associated post-industrial and post-consumer waste is difficult to measure as retailers are not in control of the manufacturing or consumer use stages of the product lifecycle (Laitala et al, 2018). It can therefore be argued that the overall durability of apparel products can be undermined when post-industrial waste is generated during production, distribution or retail, and that it is difficult to predict or assess this through LCA at the design stage (Claxton et al, 2017).

## Research Design and Methods

This paper goes on to investigate the following research questions:

1. What are the examples and causes of post-industrial waste are created in the supply chain of durable apparel?
2. How do buyers and suppliers at each stage of the supply chain attribute responsibility, find solutions and take action?
3. What are the opportunities for developing more effective practices to reduce waste that could support sustainability and circularity claims related to durable apparel?

A multiple case study approach as proposed by Yin (2018) was employed where participants were able to describe and address the specific issue and research questions. Qualitative semi-structured interviews were undertaken with seven industry experts representing five apparel companies to explore first-hand experiences of the management and mitigation of post-industrial waste problems and premature garment failure. The case companies were UK based apparel retailers and a first-tier garment supplier. Expert participants in apparel product development and supply chain relations provided information relevant to the research questions and aims of the study, having been identified by purposive selection (Maxwell 2012). Retailers A B and C are private label brands of differing size, market level and customer focus. Company D is a SME manufacturer brand with a semi-vertical supply chain. All the companies, including garment supplier E have globally diverse supply chains. Each company has a stated commitment to sustainability that could influence design strategies, although the range of initiatives varied, with only one company (B) explicitly linking sustainability to circularity.

The interviews explored eight examples of classic apparel styles designed with a 'best practice' approach to garment durability that had all failed to meet the required quality or compliance standards of the retailer resulting in post-industrial waste. Due to confidentiality requirements, Retailer B discussed a range of general examples rather than specific products. A process of thematic analysis was used to organise and code the data into categories aligned with the research questions. The case companies, research participants and products discussed are listed in Table 1.

| Company | Participant | Products Discussed |
|---|---|---|
| A: Large UK high street clothing retailer | A1 Technical Manager multi product | Men's formal trousers<br>Boy's formal trousers |
| B: Large online clothing retailer | B1 Sustainability Manager | General discussion of product problems that can occur resulting in material waste |
| C: Medium size online retailer | C1 Technical Manager<br>C2 Senior Technologist (Knitted Product)<br>C3 Senior Technologist (Accessories) | Women's jersey leggings |
| | | Women's printed silk scarf |
| D: Small cashmere brand / manufacturer | D1 Technical Director | Women's cashmere sweater |
| E: first tier supplier to a large UK high street retailer | E1 Technical Executive | Women's cotton sweater |
| | | Women's lambswool sweater |
| | | Women's acrylic sweater |

**Table 1. List of case companoes, research participants and products discussed.**

## Analysis and Discussion of Research Findings

The research findings derived from the first two objectives explored the factors leading to post-industrial waste or premature garment failure, and how buyers and suppliers within the supply chain assess, manage, and mitigate waste problems (see Table 2 for a full analysis). In response to the third objective, participants discussed how waste was accounted for within their business, potential improvements to mitigate waste impacts and increase transparency, and ways of integrating this with sustainability strategy and reporting.

### *Classification and causes of problems leading to apparel waste*

All eight garments were considered classic styles and the participants confirmed that durable design principles are commonly used within the new product development process for classic apparel using 'best practice' QA methods in line with Cooper et al's Clothing Longevity Protocol (2014). All had failed to meet the required quality or compliance standards during production and had resulted in wasted garments, fabric, or yarn. Poor production process control and inadequate risk assessment of changes to product specifications and distribution routes were found to be the main causes of waste, rather than errors in product design and specification. Four garments were affected by inadequate control of quality or manufacturing procedures resulting in inconsistent garment sizing, fabric shrinkage, fabric faults and excessive pilling; two garments were found to be non-compliant to safety regulations and deemed unsafe for wear; and the remaining two were affected by changes to the product specification or factors during transit which caused unforeseen damage to the garments.

### *Management of waste problems: finding solutions and taking action*

***Influence of supply chain stage where problem identified on waste implications:***
The different examples discussed generated waste at the manufacturing, distribution and retail sales stages of the garment lifecycle, in line with Reverse Resources' model (2017). All participants discussed the importance of finding problems early in order to reduce the scale of potential waste and lost sales. For instance, supplier E found problems early at pilot manufacturing stage for two sweater styles where a new yarn supplier or a modified yarn was being assessed. Although this caused some waste, the problems were discussed with the retail customer and resolved for the majority of the order. If problems are found following production, for instance in the retailer's warehouse, retail outlets or by customers, the opportunity to address them is more limited; the focus is on salvaging sales, learning lessons for future orders and disposing of affected stock through nominated routes. Retailer C's problem with inconsistent sizing on jersey leggings, and

| Product | Description of problem | Supply chain stage | Reason and responsibility | Action taken | Waste handling |
|---|---|---|---|---|---|
| **Retailer A** Men's and Boy's formal trousers (2 styles, same fabric). | **Safety non-compliance:** pocket lining dyed with harmful chemicals (part order). | **Retailer's stores:** due diligence testing by retailer from products in-store. | **Garment supplier.** Dyehouse sub-contracted part of the order for pocket dyeing to another dyehouse without the retailer's knowledge. | Destruction of entire stock due to inability to identify affected garments. Supplier was fined and no further business placed. | Stock was destroyed (incinerated). |
| **Retailer C** Women's jersey leggings. | **Non-conformance of sizing:** variation due to poor quality control in pressing / cutting. | **Retailer's UK warehouse:** quality inspection of delivered stock. | **Garment Supplier**. The problem pointed to poor production control. Exact reason was not discovered due to inadequate investigation. | 100% inspection of stock resulting in high rejection rate and insufficient stock availability. Entire order was returned to the supplier. | Not known what the leggings supplier did with the rejected stock. |
| **Retailer C** Printed silk scarf (continuity line with seasonal print). | **Product damage:** new adhesive care label left adhesive residue on the product. | **Consumer:** returns / complaints after handling / wearing the product. | **Difficult to assign responsibility.** Due to either inadequate assessment of new label, or change in label quality. | Scarves were reprocessed to remove adhesive. Problem persisted so they were withdrawn from sale. | Retailer sold off some of the scarf stock at public sales and remainder sent to charity. |
| **Brand / manufacturer D** Women's cashmere sweater. | **Non-conformance to fabric performance:** excessive pilling. | **Consumer:** returns / complaints after wearing the product. | **Yarn spinner**: Insufficient control of spinning process leading to brittle yarn. | Garments withdrawn from sale. The yarn was tested to identify the problem. Meanwhile, a new anti-pill finish was applied in production. | The returned faulty cashmere sweaters were donated to charity. |
| **Supplier E** Women's cotton sweater. | **Product damage:** mould found on cotton garments after shipping. | **Supplier's UK warehouse**: quality inspection of delivered stock. | **Garment supplier.** Garments became damp during storage in Bangladesh. The mould developed over the 4-6 week journey to the UK. | Re-processing of affected stock to remove mould. Humidity control system was set up in Bangladesh warehouse. | Destruction of part of the order (3,000 pieces) where mould could not be removed. |
| **Supplier E** Women's lambswool sweater. | **Non-conformance to fabric performance**: dimensional stability tests failed on pilot order. | **Supplier's Bangladesh factory**: factory QC procedures performance testing. | **Yarn spinner.** Production process control issue. Problem not present at NPD stage. | Entire order cancelled. Left-over yarn and garments were returned to the spinner who was charged for the loss. | Not known what the spinner did with the yarn and garments. |
| **Supplier E** Piece dyed women's acrylic sweater. | **Non-conformance to fabric appearance**: uneven dyeing observed when trialling a new yarn supplier. | **Supplier's Bangladesh factory:** factory QC procedures / visual assessment. | **Yarn spinner.** Production process control issue. Problem not present at NPD stage. | 100% inspection of stock resulting in high rejection rate. Left-over yarn and garments returned to the spinner who was charged for the loss. | Not known what the spinner did with the yarn and garments. |

**Table 2. Analysis of case company apparel waste problems.**

the mould affecting supplier E's cotton sweater were found on completed production orders during quality checks in UK based warehouses, and the scale of each problem was too widespread to be able to salvage a commercial quantity of acceptable product. Retailer A's men's and boy's formal trousers were found to have banned chemicals in the pocket linings following due diligence testing carried out on product taken from retail stores. Retailer D's cashmere sweater and Retailer C's silk scarf developed problems during initial use causing premature product failure and resulting in customer returns. Products were withdrawn from sale until a solution could be found.

***Approaches to waste handling:***
The case companies investigated the eight apparel styles to identify the nature, cause, and implications of the waste problem. Retailers must follow legislation relating to safety non-compliance, so company A's men's and boy's formal trousers containing harmful chemicals meant that the garments could not be sold and were destroyed by incineration. Disposal routes for the other six products shown in Table 2 were varied, and included the following: one style where part of the order was destroyed due to garments being spoiled by mould; three styles where faulty yarn, fabric or garments were returned to the supplier deemed to be responsible; and faulty garments from two styles were disposed of via sample sales and / or charity donation. Where garments or fabrics were found to be unusable through being defective, any rejected stock was seen as the responsibility of the producer and action would be taken to recover costs which included the imposition of fines for any actions contravening contractual agreements. All the retailers interviewed had a range of options and conditions for dealing with rejected stock that depended on the size and nature of the problem, although there was considerable variation in approach. Retailer A had the most formal contractual requirements for waste handling of defective garments; suppliers could elect to take the stock back, de-brand it and sell on to a different market during a later season, have it sold as 'seconds' through nominated UK factory outlets or donated to charity partners. However, in the cases of retailer C and supplier E, the eventual disposal route of defective fabric and / or garments returned to suppliers was unknown due to having no waste tracing policy in place.

*Opportunities for reducing material waste problems*

***Improving communication, trust, and transparency:***
Interviewee C2 stated that it was difficult to allocate time and resources to investigate problems with its jersey leggings, thus it remained unresolved, and the opportunities to learn lessons and improve procedures were limited. This concurs with Aage and Belussi's (2008) assertion that geographically distant global sourcing locations can prevent the sharing of knowledge and data between buyers and suppliers. Participants agreed that resolving problems originating beyond the first tier garment supplier is even more challenging as retailers have little influence on, and knowledge of processes further upstream. However, interviewee A emphasised that resolving the problem on their two trouser styles was essential as product safety is a legal, rather than a voluntary requirement, thus they were prepared to invest time and resources to visit the garment and fabric suppliers, and the dyehouse in China. All participants agreed that trust and knowledge sharing between suppliers and buyers were critical in identifying potential waste problems at an early stage and learning lessons to avoid them. That said, the findings demonstrated that retailers perceived a lack of competence and / or transparency on the part of suppliers, and the most serious waste problems contravened contractual agreements, such as retailer A's supplier's use of unauthorised sub-contracting. On the other hand, supplier E stated that it can be difficult to decide when and how to communicate a problem to the retail customer as transparency could lead to a lack of confidence and the risk of order cancellations.

***Improving waste management approaches and systems:***
Participants agreed that supply chain waste transparency between buying companies and their suppliers is insufficient to allow the development of circular approaches to waste handling, although the larger retailers had the most ambitious and formal approaches in place. Retailer B was developing a protocol for fabric or garment stock that had to be written off, and setting up a tracker to trace garments and any associated waste throughout the supply chain. Interviewee A1 stated that careful selection of waste handling partners was

imperative, and that focusing on partners with the best environmental compliance programmes should be prioritised over seeking the best price. Participants also discussed potential new CBMs such as re-manufacture of dead stock, and reverse supply chain initiatives within upstream processes as having the potential to increase resource efficiency, repurpose waste and achieve financial benefit as proposed by Reverse Resources (2017). Interviewee B1 suggested that these approaches are likely to gain more prominence as companies respond to multi-stakeholder sustainability / circularity initiatives such as WRAP's Textiles 2030 (WRAP, 2022). Retailer A had already set up an in-house team to re-design and manufacture new products from pre-consumer waste garments and fabric, selling through their outlet stores. Interviewee B1 suggested that this approach could also be outsourced to specialist re-processing companies, but would be difficult for value retailers as the cost of reprocessing could be higher than the original garment cost.

***Incorporating post-industrial waste into sustainability reporting:***
All interviewees confirmed that apparel durability was important to their brand identity and quality level, but waste created during the production and distribution of the example garments was accounted for in financial terms only, via charges covered by contractual agreements and in lost sales. Apart from retailer B who had created a collection designed with circularity principles, durability was not seen explicitly as a sustainability proposition. Participants agreed that waste levels above industry norms created by durable apparel production and supply would undermine any sustainability or circularity claims relating to extending garment lifetimes. However, it was evident from the examples discussed that waste was not fully traceable where defective fabric and garments were returned to suppliers, meaning that data to inform accurate LCA was largely unavailable. Retailer B was the only company using LCA to assess apparel sustainability, but in a very basic way to inform fibre and fabric selection at the design stage. Participant B1 stated that transparent accounting for post-industrial material waste impacts may become important in the near future due to proposed legislation on waste reduction and increasing resource efficiency, responding to initiatives such as the EU Strategy for Sustainable and Circular Textiles (European Commission, 2022). It was also suggested that including waste measurement and prevention within business sustainability strategies and reporting could improve transparency and drive more effective lean management practice and risk assessment within the supply chain as proposed by Vinhod et al. (2017), thereby supporting the move to a circular approach.

## Conclusion
Evaluating apparel durability as a circular approach has identified several issues that need to be overcome to support sustainability claims. The research demonstrates that durability needs to be measured at an individual product level to support circular business models, but that where durable apparel is proposed as a circular approach, it should not be solely assessed in the single dimension of LCA at the design stage. Garment production and supply in volume should maximise material resource efficiency and minimise waste created due to unforeseen or poorly managed commercial or manufacturing problems, and waste should be viewed as an environmental, as well as a financial impact. Solutions to address waste and support circularity should be holistically applied, crossing company boundaries and ensuring that all stages of the supply chain are included. This is necessary to address the fragmented nature of apparel supply chains, and the resultant lack of transparency and innovative solutions in managing and preventing post-industrial material waste to achieve credible sustainability improvements. A limitation of the research is its focus on UK based fashion businesses. The issues discussed could be investigated further within other product sectors and in global retail markets.

# Modeling effects of smartphone reuse on market-level lifetime and environmental impacts informed by consumer survey data: preliminary results

**Christian Clemm[a], Levon Amatuni[b], José M. Mogollón[b], Mitsutaka Matsumoto[c]**
a) Fraunhofer Institute for Reliability and Microintegration IZM, Berlin, Germany
b) Leiden University, Leiden, The Netherlands
c) National Institute for Advanced Industrial Science and Technology, Tsukuba, Japan

**Keywords**: Reuse; Product lifetime; Smartphone; Environmental impacts; Consumer survey.

**Abstract**: Product reuse is a core strategy for developing a circular economy that can minimize pressures on the environment. However, such effects are often assumed rather than quantified. In this work, we propose a method that assesses user behavioral changes due to a second-hand market and the associated environmental impacts while integrating existing primary market and product lifetime data into a stock-and-flow framework. The study found that the smartphone second-hand market is responsible for a total product use time increase of 20 %, total devices demand reduction of 27 %, and a corresponding GWP impact reduction of 23 %.

## Introduction

Product reuse is a core strategy for the circular economy and one of the traditional 3Rs, 'reduce, reuse, recycle'. Reuse is commonly believed to reduce new production and waste. However, these benefits are often assumed rather than understood, and consequently, the overall effects remain unclear (Cooper & Gutowski, 2017). Less expensive second-hand goods can grant access to consumers who would otherwise have been unable to afford the products, leading to increased rather than reduced overall consumption (a direct rebound effect). A study by Makov & Font Vivanco (2018) further discussed and quantified the re-spending effect, considering that consumers spend saved money from buying used products on other goods and services.

The rate at which reuse displaces the consumption of an equivalent new product is a key component when quantifying the environmental effects of reuse. The displacement rate depends, at least in part, on the extent to which reuse prolongs (or shortens) the lifespan of a product. Studies investigating the environmental effects of the reuse of ICT products such as smartphones or laptops, frequently make assumptions about this factor in the absence of primary data. For instance, Fangeat et al. (2022) assumed that reuse extends the lifespan of a smartphone from 3 to 5 years, thereby displacing 67 % of a new product. Other studies assume a perfect substitution in which a used product displaces a new product in a ratio of 1:1 (Cordella et al., 2021).

Other research has focused on modeling the market dynamics in presence of reuse while determining consumer preferences. Thomas (2003) estimated the shares of a hypothetical population that will purchase new or used products, or refuse altogether, as functions of a lifetime, prices, and transaction costs of transferring used goods between users. That study explored the impact of the reuse activity on the demand for primary, new products, and showed that the resulting impact on primary demand can change in different directions. However, such population shares and product lifetimes were not grounded in real data, and the actual impact of second-hand markets remains unknown.

Zink & Geyer (2017) explored multiple rebound effects related to circular economy practices such as reuse, suggesting to focus further research on empirical data, as such market effects are rather complex to predict and model. The authors conclude that most studies misleadingly assume a linear decrease on primary manufacturing due to reuse and thus no rebound effects, and that such assumptions are not grounded on empirical studies. For the case of smartphones, the authors further mention that evidence exists that they are resold to those who would otherwise not buy a new device, thereby leading to a net increase in production and consumption.

To better understand this aspect, Matsumoto et al. (2023) surveyed consumers who had experience selling or buying used phones, investigating how much longer they would have used their phones in the absence of a second-hand market without the option to buy used or re-sell. Results indicated that linear use of a phone by a single user is typically longer than when users re-sell their phone or buy a used phone. At the same time, the total smartphone lifetime that is used by several users is prolonged by 35 % on average compared to linear use, thereby potentially displacing and avoiding the environmental impacts of 35 % of a new phone.

Amatuni et al. (under review) collected primary data on the user behavior of electronic equipment, including smartphones, via a consumer survey, reporting on different types of possession spans (with or without reuse), including the total expected domestic lifespan of phones. The authors reported that the lifespan of products that are owned by multiple users is 34 % longer on average compared to a product that is only owned by a single user, which is strikingly close to the findings reported by Matsumoto et al. (2023). Yet, the study did not assess the overall behavioral change related to reuse.

In this work, we expand on previous literature by integrating primary data on smartphone longevity (Amatuni et al., 2023) and behavioral changes (Matsumoto et al., 2023) into a stock and flow model that describes the consumption preferences of users, their typical possession and use times, and the required manufacturing rates of new products. This work thereby attempts to obtain preliminary estimates for the impact of the second-hand market (reuse) on the expected lifespan of smartphones. Further, this study addresses the effect of reuse on the manufacturing rate of new products and the associated environmental burden of smartphone production and consumption.

## Methods

Modeling the effect of reuse on the average product lifetime and the manufacturing rate of new productsThe basis of our proposed model is the Markov chain described by Amatuni et al. (under review). We depict its adaptation for our purposes in Figure 1.

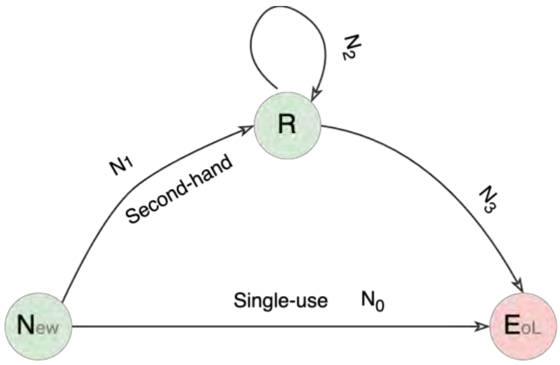

**Figure 1. Markov chain describing the stochastic model of product service life cycle, adapted from Amatuni et al. (under review).**

Four user types were identified by Amatuni et al. (under review) depending on their consumption pattern and interaction with the second-hand market. They are labeled as $N_0$ through $N_3$ in this work as described in Table 1.

| User type | Description of consumption pattern |
|---|---|
| $N_0$ | Linear use: Acquire new, use, dispose |
| $N_1$ | First use: Acquire new, use, resell |
| $N_2$ | Interim use: Acquire used, use, resell |
| $N_3$ | Last use: Acquire used, use, dispose |

**Table 1. Categorization and description of four identified user types.**

Within each user group, an average product possession lifespan has been estimated in the original study ( $LT_i$ ) along with an average hibernation time $H$ for users from various countries. In this study, around 80% of respondents were from USA. Only user types $N_0$ and $N_1$ consume new products. With  we simultaneously denote group sizes of the corresponding user types. Based on this framework, we consider the smartphone market from a stock and flow perspective. Stocks are four user groups of the corresponding sizes and use and ownership time spans. The yearly material outflows from the stocks adhere to the mass balance assumption and are equal to $f_i = \frac{N_i}{LT_i}$ . Products' transition probabilities between three states (see Figure 1) were recalculated based on such flows $f_i$ rather than the corresponding user group sizes $N_i$ as it was in the original study.

The manufacturing rate $M$ within a given time period $T$ in a market with population $P$ (sum of $N_0$ through $N_3$) can therefore be expressed as:

$$M = \frac{T * N_0}{LT_0} + \frac{T * N_1}{LT_1}$$

The resulting yearly average per-capita material (unit) requirement of smartphone consumption can be expressed as: $M/P/T$.

The expected time between the very first purchase and the end-of-life (EoL) treatment or the expected total product lifetime (TPL) of each manufactured phone has been estimated in accordance with the stochastic framework from the original study (Amatuni et al., under review).

The average product use time that, in contrast to ownership based TPL, does not include the average hibernation period $H$ can be expressed as:

$$TPU = TPL - H$$

To estimate the effect of the reuse market on the output variables M, TPL, and TPU, the stock and flow model was run using different input values for the two scenarios as described in Table 2.

| Scenario | Description |
|---|---|
| Scenario A | Scenario based on consumer surveys data to approximate the current market situation |
| Scenario B | Alternative benchmark scenario in which no second-hand market exists |

**Table 2. Description of two scenarios for comparison of impact on manufacturing rate, total product lifetime and environmental impact.**

Scenario A is based on user-reported data collected via the open consumer survey described by Amatuni et al. (under review). The ratios between user groups ($\frac{N_0}{N_1}$ and $\frac{N_2}{N_3}$) are based on the number of corresponding reports in the original survey (102 respondents). Given these data inputs and the mass balance equations from the stock and flow model, resulting sizes of the user groups along with the magnitudes of flows between them were obtained, hence, defining the existing market setting in the form of defined stock and flow model. The relative consumer group sizes and the average lifetime of smartphones by each user type are reported in Table 3. Lifetimes include the active use span and hibernation times. The market-average hibernation time across all user types was 0.9 years.

| User types | Relative user type occurrence (P=1) | Lifetime types | Average lifetime [years] |
|---|---|---|---|
| $N_0$ | 0.45 | $LT_0$ | 3.7 |
| $N_1$ | 0.23 | $LT_1$ | 2.9 |
| $N_2$ | 0.17 | $LT_2$ | 2.2 |
| $N_3$ | 0.15 | $LT_3$ | 2.2 |

**Table 3. Input parameters for scenario A (actual scenario with second-hand market).**

As has been shown by previous studies, assuming no behavioral change and rebound effects caused by the possibility to participate in the second-hand market, can be misleading. Hence, it would not be correct to assume that in scenario B, all users would use devices for the same length. Yet, no primary data can be collected for the fictitious scenario B in which no second-hand market exists. To estimate user behavior in this scenario, insights on the effects of a hypothetical absence of a second-hand market reported by Matsumoto et al. (2023) were utilized to 'convert' user types $N_1$, $N_2$, and $N_3$ into $N_0$. Accordingly, user type $N_1$ would use their phones longer by 33 % if re-selling was not possible. User type N3 would use a new phone longer by 62 % if buying a used phone was not possible. Both factors were applied to intermediate user type $N_2$ in the absence of survey data. These factors were applied to $LT_1$, $LT_2$ and $LT_3$ to estimate $LT_i'$ in absence of a second-hand market. Values $LT_1'$, $LT_2'$, and $LT_3'$ were combined with the original $LT_0$ to estimate the modified $LT_0'$ in the market everyone practices single-use behavior. Table 4 reports the resulting values.

| User types | Relative user type occurrence | Lifetime types | Average lifetime [years] |
|---|---|---|---|
| $N_0$ | 1 | $LT_0'$ | 3.8 |
| $N_1$ | 0 | $LT_1'$ | 3.9 |
| $N_2$ | 0 | $LT_2'$ | 4.7 |
| $N_3$ | 0 | $LT_3'$ | 3.6 |

**Table 4. Input parameters for scenario B (benchmark scenario where second-hand market would not exist).**

### *Estimating environmental effects of reuse*

Here, the environmental impact related to the consumption of smartphones is calculated by multiplication of the total demand for new smartphones $M$ with the global warming potential (GWP) factor $G$ related to the non-operational life cycle phases of a single smartphone:

$$(1)\quad E = M * G$$

Operational impacts arising from smartphone use, i.e. emissions from provisioning of electricity for battery charging, are not included, assuming that the total population-wide use time is identical in both scenarios and power efficiency increases with newer smartphones are negligible.

The value for G is derived from the Ecodesign preparatory study for smartphones (Schischke et al. 2020), where base case 2 is a fictitious smartphone with typical mid-range specifications associated with a life cycle GWP of 32.2 kg $CO_2e$ for the non-operational life cycle phases (material acquisition, manufacturing, distribution, disposal) after deducting credits for recycling.

No primary data was available the share of phones that undergo additional treatment such as repair, refurbishment or remanufacturing. Instead, it was assumed that 50 % of all phones transferred between users undergo refurbishment. Based on Fangeat et al. (2022), refurbishment processes, including transportation, result in 3.8 kg $CO_2e$ per phone per year of use. That estimate was added to 50 % of all phones transferred between users. Transaction impacts of phones that are not refurbished are considered negligible.

## Results

Running the model (eq. 1) based on the primary market data reported in Table 3 and estimated market data in Table 4 resulted in the values for total manufacturing rate per 100 users ($P = 100$), total product lifetime and total product use time reported in Table 5. As shown in Table 5 and illustrated in Figure 2, the existence of the second-hand market increases the total product use time by 20 % and reduces the demand for new smartphones by 27 %.

| Output variable | Unit | Results of scenario A | Results of scenario B |
|---|---|---|---|
| M | Units | 27 | 37 |
| TPL | Years | 5.4 | 3.8 |
| TPU | Years | 3.6 | 3.0 |

**Table 5. Results of the scenario based on consumer data (A) and the benchmark scenario without second-hand market (B).**

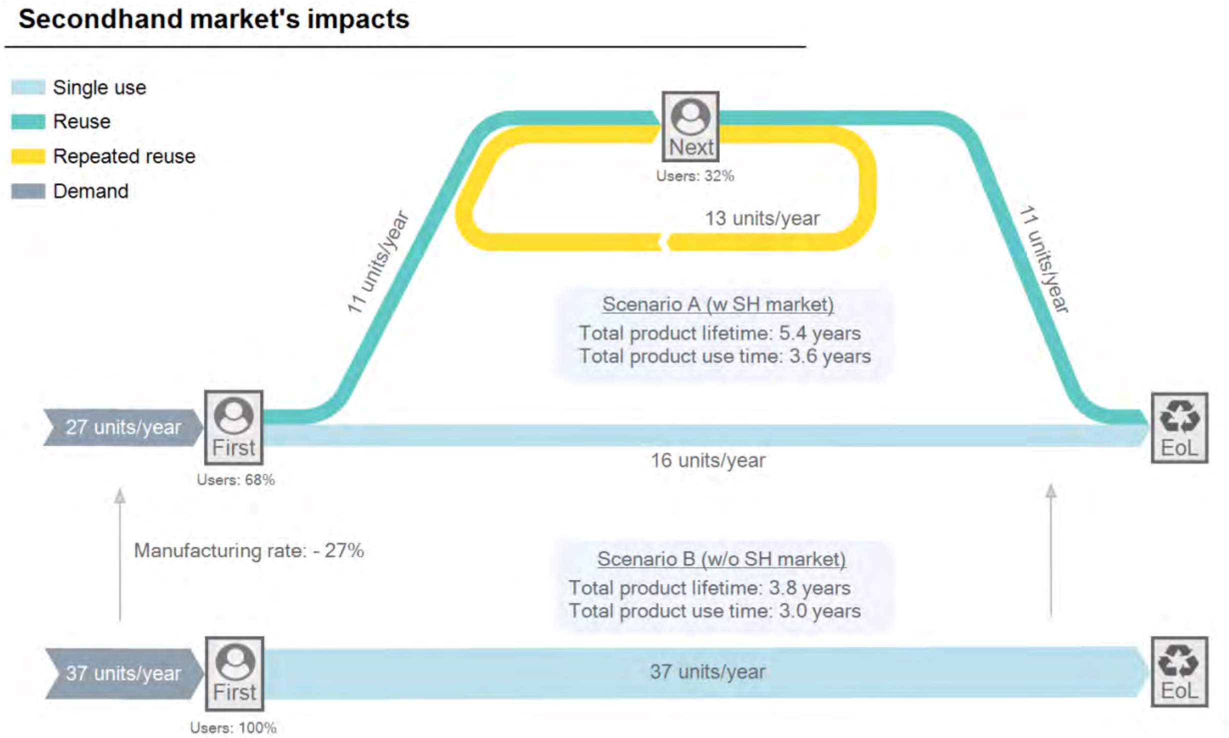

**Figure 2. Sankey diagrams depicting the total demand for new smartphones and the flow between user types until products reach end-of-life in a benchmark scenario (A) based on surveyed consumer data and a scenario without a second-hand market (B) estimated from consumer data in a market with a population of P = 100; SH = secondhand.**

The environmental impacts calculated for both scenarios are depicted in Figure . Total users' interaction with the second-hand market enables avoidance of 23 % of GWP due to the more effective use of fewer manufactured smartphones. At the same time, we estimated that another 11% could be decreased if, while still participating in reuse, users would not shorten their ownership spans of reused products compared to new ones (rebound effect). Another 4% increase was explained by the additional transaction costs.

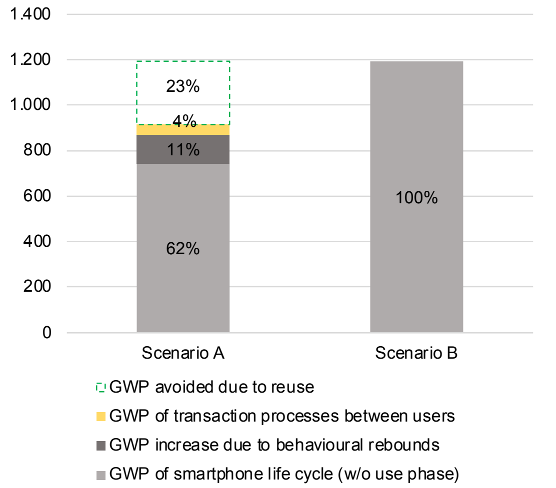

**Figure .: Global warming potential calculated for both scenarios based on a population of P = 100 for the time period of one year.**

## Discussion and Conclusions

In this work, we proposed a stock and flow model method to estimate the total population's manufacturing requirement and the associated environmental impact depending on actual data on average product life and use times and user behavioral changes caused by the interaction with the second-hand market of smartphones. Two scenarios were compared to provide preliminary estimates of the impact of the existence of the second-hand market. The study found that the smartphone second-hand market is responsible for a total product use time increase by 20 %, total devices demand reduction of 27 % and a corresponding GWP impact reduction by 23 %.

Although this study accounts for rebound effects associated with users' interaction with the second-hand market, being shorter use times for the individual users of a product with multiple owners along its life cycle, other rebound effects, such as the re-spending effect addressed by authors such as Makov & Font Vivanco (2018) are not addressed here.

Major limitations of the study are related to the multi-regional nature of the survey data and uncertainty with some of the user behavioral patterns like the discard rate of the existing second-hand products, and rebound factors exhibited by $N_2$ type of users. Additionally, we have assumed that the entire population uses smartphones regardless of the availability of new versus used devices, hence, overlooking the possibility of some users making a purchase only when a second-hand product becomes available, which could amplify the negative environmental aspects of reuse. Finally, one device per user was assumed.

As a continuation of this study, more consumer surveys and real market data analysis will be conducted to address the above-mentioned limitations.

## Acknowledgments

This work was in part funded with a personal fellowship from the Canon Foundation in Europe and EIT Raw Materials.

# A socio-technical critique on the future use of digital technologies for clothing manufacturing

**Ms Rachel S. Cox, Dr Amy V. Benstead, Dr Rosy Boardman & Dr Steven G. Hayes**
The University of Manchester, Manchester, England, UK

**Keywords**: Digital, Manufacturing, Social, Sustainability, Fashion.

**Abstract**: There is currently a great emphasis on digitalisation and more technological integration within clothing manufacturing. This includes additive manufacturing, cloud manufacturing and Internet of Things-based technology. Digitalisation paves the way for opportunities such as distributed manufacturing. It is unclear how this will impact garment workers within the UK fast fashion and ready-made clothing industries; in particular, the impact on the speed at which workers are expected to produce, which some sources have linked to poor worker welfare and a lack of social sustainability (Hohn and Durach, 2021; Ozdamar-Ertekin, 2016). Drawing on academic and industrial sources, this conceptual study adopts a narrative literature review to analyse the current digital technology trends starting to be used and suggested for the future of fashion clothing manufacturing. Socio-technical systems theory (STS) is used to critique current sources to analyse how digitalisation within production supply chains could impact garment workers including the benefits and drawbacks of more digitalisation within a geographically localised ecosystem/s. Furthermore, it explores how digital technology could be used to value and empower workers in the context of localised and distributed fabrication within the UK. The result of the secondary analysis will be used project considerations needed for such integration and use of digital technology to contribute to better socially sustainable practice in fashion production. Overall, this study will provide future research suggestions around digital manufacturing considerations in fashion and clothing as well as the importance of involvement of makers and producers for decision-making within digital production of ready-made clothing.

## Introduction

Digitalisation is being explored within the fashion industry (Nouinou et al., 2023; Teunissen and Bertola, 2018; WhichPLM, 2022). Digitalisation and localised manufacturing are current discussions within UK fashion and clothing production (Harris et al., 2021; Hetherington et al., 2022; House of Commons, 2019). The UK fashion industry has seen a resurgence from increased interest for localised clothing manufacturing including a drive for reducing lead-times (Rashid and Barnes, 2017; Camargo et al., 2020) as well as a greater perception of transparency around social sustainability issues (Fashion Revolution, 2021). Some highlight the industry's late technology adoption (Harris et al., 2021), identifying concern around technical capacity, particularly in mass production, putting the UK at risk of lower global competition. Reports and documentaries have exposed poor working conditions of garment workers (GWs) in UK ready-made-garment (RMG) production (O'Connor, 2018; Hadland et al., 2017; Hammer et al., 2015; HomeWorkers Worldwide, 2017; Labour Behind the Label, 2020), demonstrating a lack of social sustainability existing within clothing production. Minimal literature questions the impact speed has on GWs (Hohn and Durach, 2021; Ozdamar-Ertekin, 2016), some relating specifically to digital technologies (Hohn and Durach, 2021) and little within the UK context to the authors' knowledge. There is very little research exploring social issues and impact in circular economies (CEs) (Murray et al., 2017) and non-linear production systems. Nouinou et al. (2023) and Khin and Kee (2022) raise concern around digital technology's impact on job security. Bragança et al. (2019) note technological advancements have improved human aspects of manufacturing such as worker safety. It is unclear how this increase of digitalisation in production may translate to working conditions and expectations of GWs. This paper explores current themes within academic and industrial literature through a narrative review surrounding the potential impact of digital technology on working conditions of GWs through a Socio-Technical-

Systems (STS) lens and making suggestions for future CE research.

## Method

Narrative reviews are appropriate if the area under investigation has been explored by various groups of researchers from diverse disciplines (Wong et al., 2013). Conceptual and scoping approaches are used to critically synthesise literature making future research suggestions (Jesson et al., 2011) from academic and industrial literature including but not limited to government, NGO and research institutions. It questions under-explored areas within digital manufacturing that may have an impact on GW working conditions. calling for more interdisciplinary research not limited to business and operations management journals (Sehnem et al., 2019). Areas such as operations management, clothing and fast fashion, digital technologies in manufacturing, STS, welfare and social sustainability are brought together in an interdisciplinary manner highlighting themes to create a future research agenda using an STS lens. It explores how research can be worker-centred in the digital manufacturing of clothing products, and the influence and role this has on product lifetimes and CE. The search strategy used Google Scholar, Emerald Insight, ScienceDirect, The University of Manchester's library and Google to find peer-reviewed academic articles, book chapters and industry reports. Keywords included: manufacturing, fashion, clothing, garment worker, working conditions, exploitation, modern slavery, circular economy, UK, digitalisation, workload, STS, fast fashion, cut-make-and-trim (CMT), RMG, Industry 4.0 (I4.0) and Industry 5.0 (I5.0). Current trends in digital manufacturing as well as theoretical and contextual understandings in RMG working conditions were gained. This enabled flexibility in finding context relevant STS perspectives, also noticing what was not present through neglect spotting (Sandberg et al., 2011).

## An overview of STS theory

This study focuses on social sustainability concerning people within fashion supply chains, specifically GWs who make and produce clothes. STS focuses holistically on dynamics and interdependencies between people (socio) and technology (technical) within organisational structures (Appelbaum, 1997; Gattorna and Passmore, 2022). This systems-based theory was pioneered in the 1960s by the Tavistock Institute (Appelbaum, 1997; Trist et al., 1993) and developed since (i.e. Cherns, 1976; Mumford, 2000). STS instigates human centricity in technology management within an organisation (Appelbaum, 1997; Bednar and Welch, 2020). Cherns (1976) explains a social system must exist for a production system to operate. Appelbaum (1997) argues STS is for the empowerment of people within organisations through greater flexibility and autonomy around work design. Gattorna and Passmore (2022; p.492) discuss this "Work System" aspect of STS. Bednar and Welch (2020) suggest working with a systems theory allows a phenomenon to be observed through interactions of each system element. Gattorna and Passmore (2022) suggest that more technology introduced and developed calls for involvement of the people interacting with the technologies in their adoption. Mumford (2000) notes STS promotes the inclusion of users at multiple levels of technology design, though is often not the reality when technology design challenges power structures. Mumford (ibid.) highlights the importance of motivation of technology development serving to reduce disparity between economic and social challenges. This indicates STS has the capability to centre social considerations for sustainable technology management.

## Findings & discussion

### *Fast fashion production in the UK*

Poor working conditions in a UK context relate to low wages, health and safety hazards (O'Connor, 2018; Hammer et al., 2015; HomeWorkers Worldwide, 2017), labour intensity, pressure and working time often leading to worker stress (Hammer et al., 2015; Taplin, 2014). Crane (2013) models working conditions such as labour intensity, as the foundation for exacerbating practices of worker exploitation and in severe cases, modern slavery. Speed is a common motivation in digitalised information systems for production. This is highlighted as a benefit in lowering production costs (PWC, 2016), increasing business profits (Harris et al., 2021) and shortening delivery lead-times. Froy (2019) indicates importance of fast fashion brands increasing economic potential within the UK. Fast fashion and ultra-fast fashion (Camargo et al., 2020) are built on quick response (QR) strategies (Hammer and Plugor, 2019; Taplin,

2014) involving fast production (Anguelov, 2015). Viewed as a "race to the bottom" (Fletcher and Tham, 2019; p.17), this speed is often driven by financial cost pressures (Lulani and Metcalf, 2012) and fast market response (Anguelov, 2015). Some fast fashion brands have strategically sourced local production to achieve fast product to market through closer geographical proximity between corporate and manufacturing operations (Mooney & Nilsson, 2020; Hammer and Plugor, 2019). Some as little as one to two weeks, design to customer (Hendriksz, 2017). Forza and Vinelli (1997) link QR-driven strategies with information and physical flow speed within fashion and textiles manufacturing (p.130). Much fashion management literature discusses fast fashion speed from a business-centric approach (i.e. Doyle et al., 2006; Parker-Strak et al., 2020; Runfola and Guercini, 2013), failing to consider consequences of this speed on GWs. Watson and Yan (2013) argue fast fashion has been justified given the attributed success and dominance of retailers. Ozdamar-Ertekin (2016) explores speed within fast fashion production demonstrating links with producer welfare and stress as well as fear around slower paces and job losses as a result. This research indicates a clear theme of speed taking top priority within fast fashion supply chains whatever the implications.

### *Digital manufacturing technology and the CE*

Speed is a dominant theme in digital technology literature (Dos Santos et al., 2021; Paritala et al., 2017; PWC, 2016; Veile et al., 2021). Levin (1993; p.489) refers to technology as "physical objects", "processes" of these and the "knowledge" required for their operation. Levin (1993; p.499) highlights the human interaction and involvement, recognising technology as a "social product". I4.0 literature encompasses a variety of digital technologies including IoT/IIoT, big data, blockchain, additive manufacturing and cloud computing. A common depiction of digital technologies includes a "hyperconnected manufacturing chain" (Ghobakhloo et al., 2021; p.1535). Øvrelid et al. (2019) describe digital infrastructures as "interconnected systems", and the users within (p.222). Digital information systems bring greater connection and speed for better efficiency, productivity and profits (Dos Santos et al., 2021; Ghobakhloo et al., 2021; PWC, 2016; Taifa et al., 2020a; Veile et al., 2021). Digital technology is capable of transferring information and data between machinery used within working systems. Products produced and consumed in CEs use a "cradle-to-cradle"® approach (McDonough and Braungart, 2003; p.13), designing out waste (Ellen Macarthur Foundation, 2015) through closed-loop infrastructure (Castro et al., 2022). Nouinou et al. (2023) suggests digital technologies can enable circular business models, demonstrating how technologies can be used at different product lifecycle stages (see p.14).

### *Infrastructure & organization*

Organisation of production infrastructure is discussed within literature. It is interlinked with the use of digital technologies through the ability of information systems to connect geographical clusters of production together for workflow management (Srai et al., 2020; Srai et al., 2016). Infrastructure and organisation are key parts of STS (Davis et al., 2014). Distributed manufacturing comprises multiple firms geographically widespread within or across regions (Montreuil et al., 2000; Srai et al., 2020; Srai et al., 2016). Organizational capabilities of digitalisation could act in workload allocation to suppliers across regions i.e. equitable order sharing (Taifa et al., 2020). Hirscher and Fuad-Luke (2013; pp.174-195) model conceptual networks between designers, producers and new actors within "open participatory design". They depict collaborative opportunities across producers (Ellen Macarthur Foundation, n.d.). Digital systems could influence workload management through the speed of sending and receiving information to and how this translates to working expectations. CE research could investigate how digitally reliant organisational systems may adopt product repairs and reproduction processes and what impact this may pose on GWs. Buyers would need to be aware of a supplier's capabilities such as worker skills and current workload capacity overall. Future research should consider features of the design of information systems to be able to clarify worker capability at a supplier in relation to product durability design and repair skills. Case studies of specific manufacturing firms and current technologies could provide contextual insight.

*Connectivity of information systems*

Literature conceptualises the capability for digital technologies to form connected manufacturing networks. Dos Santos et al. (2021) produced conceptual network configurations of digital information technology. Noori and Lee (2006) conceptualise a central hub distributing information to multiple enterprises. This indicates potential for greater speed and flow of information as well as greater control over how the speed and flow of information is processed and acted upon. Veile et al. (2021) argue that I4.0 technologies increase the intensity of buyer supplier relationships (BSRs). Increased cooperation, trust and long-term nature of BSRs are discussed as a result. Cost and lead-time pressures from fast fashion are justified by consumer demand for constant newness (Barnes and Lea-Greenwood, 2013) and buyer order pressures on suppliers (Hammer and Plugor, 2019; Taplin, 2014). Ozdamar-Ertekin (2016) frames technology as an enabler for fast fashion systems getting faster. Veile et al. (2021)'s argument also suggests this connectivity has potential for quicker and clearer responses for managing work intensity. Future research can explore motives of developing and implementing digital technologies for CEs and the social consequences. For example, how greater intensity of information flow in BSRs could translate to expectations and labour intensity of GWs and where this may create challenges based on skills needed for services such as repairs. Research could also focus on product longevity and consumption speeds through a production-centric STS lens.

*I5.0: A facilitator for worker voice*

I5.0 is the "fifth industrial transformation" (Elangovan, 2022; p.8), building on I4.0's digitalisation focus. I5.0 recognises the importance of human design (Hughes in St John, 2021) as well as promoting "human centricity and social needs" (Leng et al., 2022; p.280). I5.0. centres human welfare contributions, not just productivity and efficiency (European Commission, 2021). To date there is little presence of I5.0 within the fashion industry to the authors' knowledge. General I5.0 literature reflects the drive for worker-centricity and greater social focus within manufacturing (Maddikunta et al., 2021; Nahavandi, 2019; Yang et al., 2022). Despite the use and drive for more digital information systems in supply chains, the fashion industry is reliant upon people to produce clothes, therefore valuing the contribution of worker voices in research is vital to meet the needs and aspirations of garment workers (Thomas, 2018). Hohn and Durach (2021)'s sampling appears to not include current GWs despite drawing upon expert opinions on social sustainability and working conditions within additive manufacturing. Worker voice as a methodology within technology management is a highly important strategy going forwards, using stakeholder theory to facilitate this approach and general consideration of stakeholders within fast fashion supply chains (Ozdamar-Ertekin, 2016; p.27). Future research should include viewpoints from GWs around technology innovation management and design within CEs to increase social sustainability within RMG production. It is challenging to fully replicate human finesse required for a RMG apparel pipeline (Salahuddin et al., 2022). Carr (1972) emphasizes importance of the "ability, skill and enthusiasm" (p.101) of the people producing clothing regardless of infrastructure and machinery. Research could look at the co-existence of individual skills with use of technology in the manufacturing of products with a long lifetime.

*Techno-stress*

Erebak and Turgut (2021) studied the impact of automation and speed of technological development on worker's stress levels. The "white-collar individuals" (p.4) sample indicates working role context difference to GWs. Though the study was not sector-specific,19 out of 243 participants worked in "Textiles, Clothing Leather" (p.4), demonstrating some industrial context reference. Bragança et al. (2019) raise concern of workers experiencing "mental stress to worker", p.645, via collaborative human-computer interactions. Research links labour intensity with working conditions (Crane, 2013; Hammer et al., 2015; Taplin, 2014). Hammer et al. (2015) reiterate speed playing a role within UK working conditions. Veile et al. (2021)'s work on BSR intensity increase from digitalisation suggests possibility to translate onto GW workload expectations. In the additive manufacturing context, Hohn and Durach (2021) highlight a consensus of additive manufacturing lowering labour intensity through reducing health and safety concerns in specific higher risk tasks. However they also indicate those "unskilled" (p.1052) are more vulnerable to job losses as a result, and encourage future research to challenge technological developments, but within a Global South context, though is still applicable to the UK context explored. Socio-psychological perspectives would provide relevant contributions to focus on GW welfare at the centre of technology management. Methods should again include worker voices for greater inclusion of relevant experience. Research could focus on retailer and consumer awareness of manufacturing speed in relation to product value and how this impacts product longevity through product use.

## Conclusion

This review provides future research suggestions for CE and product lifetimes from an STS standpoint around digital technology and working conditions for GWs within the UK RMG context. Figure 1. has been conceptualised to summarise this.

## Limitations

This is an interpretative conceptual analysis based on secondary resources. It is a qualitative study to help readers critique the potential use and misuse of digital technology within manufacturing environments and how this can contribute to product lifetimes. While suggestions are made, ideas should not be generalised given the exploratory nature of the traditional literature review (Jesson et al., 2011). The importance of worker voice highlighted has been based on research where some but not all sources reviewed have included GW voices in their research. The context is primarily focused on applying literature to working conditions within the UK RMG industry, so may not be applicable to other geographical or industrial contexts.

## Acknowledgments

This research is funded by the Engineering and Physical Sciences Research Council (EPSRC), UK Research and Innovation (UKRI).

# Does Resale Extend the Use Phase of Garments? Exploring Longevity on the Fashion Resale Market

**Mette Dalgaard Nielsen**[a]**, Else Skjold**[b]
a) Royal Danish Academy, Copenhagen, Denmark
b) Royal Danish Academy, Copenhagen, Denmark

**Keywords**: Fashion Design; Sustainability; Resale; Circularity; Longevity.

**Abstract**: This paper presents a follow-the-garment exploration in which the two Danish fashion brands GANNI and Baum und Pferdgarten (BuF) have been followed in selected resale environments from September 2020 to September 2022. Drawing on data from two pilot studies and an ongoing PhD project which is part of the large-scale Danish research program TraCE (trace-im4.dk), an actor-network theoretical (ANT) case study approach is used to explore how mechanisms on the resale market can inform design strategies with the purpose of extending the use and lifetime of garments. Following the idea that design strategies can be improved by studying actual examples of garment trajectories, the resale market is proposed as an appropriate field of research to explore mechanisms that determine how garments perform in circular business models. As resale is considered one of the most effective circular business models in the fashion sector (Niinimäki, 2018), we dive into the market to stimulate a shift in gears from theoretical possibilities to design for longevity and to practical realities where garments are shifting hands. The paper contributes with insights that can further understandings of relationships between fashion design and resale mechanisms and finds that design for longevity strategies are limited in their possibilities to succeed due to the dynamic existence of garments whose destinies rely on user behaviours and are modified with everything that happens with and around them.

## Introduction

This paper sheds light on mechanisms in selected resale environments to explore *why*, *when*, *where* and *if* different types of fashion design perform well in circular business models. Focusing on the following research question, we unfold three examples of mechanisms that can deepen understandings of possibilities for circular business models to extend the use and lifetime of garments through resale and design strategies:

*How do design strategies for extended use and product lifetimes align with mechanisms on the resale market?*

We draw on a case study approach in which the Danish fashion brands GANNI and Baum und Pferdgarten (BuF) have been followed in selected resale environments over a two-year time period. As such, we do not provide generalisable answers that are representative of all brands in all resale environments but follow the journeys of selected garments to examine how ideas about design strategies for longevity resonate with mechanisms on the resale market.

## Design for Longevity

Design is not a straightforward process where input *a* (design methods for longevity) necessarily results in output *b* (long-lasting design). Thus, in this section, we present a variety of scholarly contributions that describe design for longevity as a nonlinear concept whether the strategy is directed toward *technical, functional, aesthetic* and/or *emotional* durability (Hasling & Ræbild, 2017). Leaning on Fletcher's idea that design for longevity strategies are necessary but neither suffice to extend use or product lifetimes (2017), we argue that garments are entangled in intertwinements of situated, systemic and contextual parameters that influence their lifespans.

Theoretically, garment lifetimes should be extended by improving the overall product strength through quality and durability upgrades (Akko et al., 2022). However, just because a product *can* last, there is no guarantee that it *will* last. As Chapman exemplifies, it is relatively easy to design a t-shirt that can last physically for 15 years, while it is strangely difficult to design a t-shirt that someone will want to use and keep for 15 years (2015:74). Thus, while durable product attributes are necessary, a strict focus on material qualities may prevent designers from responding adequately to the issue of increasing longevity (Neto & Ferreira, 2023).

Irrespective of the design strategy applied, the use and lifetime of garments is unlikely to be extended without reductions in wardrobe volumes and the total number of garments in circulation (Maldini et al., 2019). While design for emotional durability has gained traction as a winning strategy to enhance garment lifespans, research supporting the relationship between strong emotional product attachment and increased use is lacking (Fletcher, 2017:7). The same applies to other strategies that are expected to deliver climate and environmental benefits but lack empirical validation. According to Maldini et al.'s review of sustainable fashion strategies neither *production on demand*, *service-based models*, *user involvement*, *multifunctional/transformable/modular garments* or *design for slowness, longevity and repair* have been verified to work in practice (2017:233). However, there is scarce data on how garments actually perform in the hands of users, how long they are used for and in what ways such issues are site-specific and context related (see e.g. Wiedemann et al., 2020).

Perceiving longevity as a decentralised human-object-reliant concept, Fletcher and Fitzpatrick define durability as a diverse and heterogeneous concept that "exists in all contexts" (2021:3). In this relation, Fletcher argues that longevity is a disruptive process that is achieved through the "craft of use" (2016). Craft of use emphasises the impossibility of designers to control garments beyond the design phase and is based on the idea that garment lifetimes rely more on everyday practices of use than design strategies. A perspective that is supported by other researchers, including Gill and Lopes who write that a more sustainable material culture is perhaps "more about making new relationships than making new things" (2011:307).

In this paper, we argue that complex mixtures of situated, systemic and contextual parameters play a profound role in shaping garment lifespans. Following the nonlinear and difficult relationship between design strategies for longevity and actual garment trajectories, we direct our attention to resale mechanisms that hold rich information about integral garment dependencies. As such, we follow the suggestion of Gill and Lopes who argue that the already made hold insights that enable designers to work backwards (2011).

## Methodology

The paper relies on actor-network theoretical (ANT) inspiration that situates garments as co-dependent and world-making phenomena that are intertwined with multiple agents of change and stabilisation (Latour, 2008). With ANT, objects can only be understood through their entanglements which means that neither garments, nor users or their surroundings can be seen as stable entities (Yaneva, 2009).

We draw on data from two pilot studies and an ongoing PhD project that is facilitated as a partnership between Royal Danish Academy and 18 companies with different business models. Special attention was given to the brands *GANNI* and *Baum und Pferdgarten* (BuF) who were followed in the following resale environments through fieldwork and netnography (Kozinets, 2019) from September 2020 to September 2022:

1) *Trendsales*, the largest peer-to-peer platform for pre-owned fashion in Denmark
2) *Vestiaire Collective*, one of the largest peer-to-peer platforms for pre-owned fashion internationally
3) *Facebook Forums* for resale
4) Local hybrid/physical resale concepts such as *flea markets* and *consignment shops*.

Based on the observation of more than 5000 active resale listings, data (e.g. images, product category, listing price, condition, material composition, sizing) from more than 50 individual designs were registered and analysed in and across time and resale environments.

By stretching over two years, the data are comprehensive and reflect changes in trends, seasons and other circumstances that can only be achieved over time. Out of several possible themes, we have committed this paper to three resale mechanisms that can inform design strategies for longevity.

## Analysis

*Mirroring the Conventional Fashion Market*

While our fieldwork and netnographic explorations took off within selected resale environments, it did not take long for our attention to be redirected to the conventional market as we were met by strikingly recent designs: garments that were available in the conventional market were often available in the resale environments too (Figure 1). Further, it was not unusual to identify more resale versions of the same designs which were e.g. listed in different colours, sizes or geographical areas and in more of the resale environments simultaneously.

To some degree, the resale market appeared to mirror the conventional fashion market by providing access to resale versions of current designs. The resale versions were often listed with more or less symbolic discounts relative to their first-hand prices which seemed to provide a baseline for the resale valuations. This became apparent when the seasonal sales hit the conventional market, and the price reductions enforced comparable price reductions in the resale environments.

When designs had sold out in the conventional market, it could stimulate hype-like movements in the resale environments. This emerged e.g. from what we have termed “Asking ads” where users sought for specific designs that were no longer available for first-hand purchase. Asking ads appeared often to be self-confirming and boost the desirability of the asked for garments more generally. Thus, when someone asked for a design, it seemed to strengthen the overall garment awareness and inspire others to ask for the same design. In this way, users seemed to confirm each other in the appeal and desirability of certain designs.

**Figure 1. Resale versions of BuF AW21 designs. The Delaware Coat and ABI Dress were spotted in the consignment shop *KLAEDER 2.Hand Luksus* on 22.09.2021, just as the collection had launched © BuF.**

*Reflecting Changing Weathers*

While the previously described resale mechanisms seemed to mirror mechanisms on the conventional market, the explored resale environments did more than mimic the fashion calendar. In fact, they seemed highly influenced by weather changes which gave the impression that users want functionally durable garments that match their time-specific contextual needs. Thus, in this section, we focus on local and weather-related mechanisms.

When it rained, rainwear and rubber boots were in demand, when it snowed, it was winter coats and sweaters, and when the summer temperatures were extended a few months, so was the demand for sundresses. The weather-determined preferences appeared both from swift oversupplies of seasonally specific designs from the prior season and the lack of specific seasonally relevant designs for the season taking over (Figure 2).

While the local, weather-related mechanisms appeared highly influential to the explored resale environments, they were strangely disconnected from the conventional market. Thus, in this relation, the resale environments seemed to expose the counterintuitive logics of the conventional fashion calendar which does not reflect the most prevailing user needs on local and temporal scales (Fletcher & Tham, 2015). Due to the apparent importance of functional use relevance, we draw attention to the question of how resale may influence garment-relationships for resale suppliers, i.e. users, in the following section.

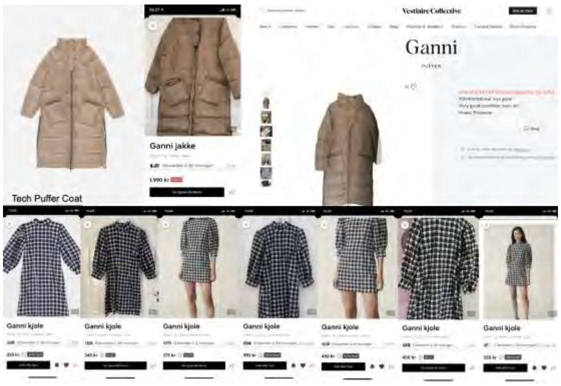

**Figure 2. 1) Example of ‘asked for’ GANNI design (Tech Puffer Coat), showcasing the preference for functionally durable design. 2) Example of a seasonally specific GANNI design (Seersucker Check Dress) that was widely available after the summer of 2022. © GANNI.**

### *Preserving the New-Like Appearance*

From the perspective of the explored resale environments and the rapid conversion of new garments to resale garments, the resale option seems to encourage a material culture of non-binding garment relationships. In this section, we draw attention to resale’s validation of such garment relationships and ask how the resale possibility may impact product care and maintenance.

Based on our explorations, it seems reasonable to argue that resale shapes user behaviours, firstly by legitimising half-hearted purchases, and secondly by encouraging users to perceive these purchases as investments. As the resale market relies on the willingness and capability of users to deliver excellent supplies of pre-owned garments, it is interesting to explore how it shapes their behaviours in terms of product care and maintenance. Across the explored resale environments, ‘product condition’ revealed itself as a highly important factor. Thus, the presence of the resale option may create incentives for users to treat their garments extraordinarily well.

While we cannot determine the correlation between product condition and resale performance in this study, our data give the impression that the resale performance of GANNI and BuF designs depends on their approximation to a ‘like-new’ appearance. Throughout the data collection period, the explored resale environments were loaded with garments in excellent condition, sometimes despite being several years old. As such, the possibility for users to grow revenue streams out of their wardrobes may positively impact product care and maintenance, even when human-garment relationships are non-binding.

## Discussion

Just as the conventional fashion market, the resale market is influenced by multiple mechanisms that guide garment trajectories, regardless of their intrinsic, material attributes. As it appears from our analysis, garments rely on a variety of mechanisms that determine how they perform through use and on the resale market. This poses questions to understandings of longevity as an exclusively design-reliant concept.

In the explored resale environments, the performance of GANNI and BuF designs seemed e.g. related to mechanisms from 1) *the conventional fashion market,* 2) *changing weathers* and 3) *new-like product appearance* which support the idea that longevity has as much to do with the variable contexts that designs are intertwined with as the designs themselves. Thus, design strategies that are systemic and encapsulate both the complexity of human-garment relationships and their dependencies are needed.

The explored resale environments seemed to mirror movements on the conventional market, including its culture of rapid garment relationships. In this relation, the frequent introduction of new collections that leads to recurring discount cycles on the conventional market had a negative impact on resale performance: when designs were sold on discount, they seemed to lose monetary value in the resale environments as well. Other research has too pointed to relationships between movements in the conventional market and the resale market (Sihvonen & Turunen, 2016; Choi & Kim, 2019). A relationship which appeared to shape patterns of supply and demand in both markets in our explorations where the performance of designs seemed to follow a predictable rhythm that, again, had more to do with mechanisms than design attributes.

The tendency for seasonally relevant garments to perform well, makes us assume that they are primarily purchased to be used rather than resold. Thus, as users did not appear to purchase with the *intent* to resell, we like to think of them as purchasing with the *possibility* to resell. At least many garments from GANNI and BuF revealed themselves as promising investments. While considering garments as investments and purchasing them with the resale possibility in mind may express a culture of non-binding garment relationships, it can positively impact how garments are treated: when users consider garments as valuable, it is likely to affect their behaviours. Thus, the resale possibility may positively impact human-garment-relationships in terms of product care and maintenance.

As stated initially, emotional product attachment does not necessarily increase use. Thus, in this light, the non-binding garment relationships may limit the accumulation of inactive garments in private wardrobes. According to a survey by Laitala and Klepp, reused garments are, nevertheless, used 30% less than garments acquired from new, while garments that are set to be donated or resold are used 22% less than garments planned to be thrown away (2021). On this notion, we will finish the discussion by stating that our data do not indicate that resale lives up to its reputation as a provider of extended use and product lifetimes - and that academia, as far as we know, offers no such evidence.

## Conclusions

Focusing on GANNI and BuF, we have committed this paper to explore how design strategies for extended use and product lifetimes align with mechanisms on the fashion resale market. The resale performance of garments has been shown to rely on a variety of non-material mechanisms exemplified through *the conventional fashion market*, *changing weathers* and *new-like product appearance.*

Focusing on resale mechanisms rather than intrinsic and material design attributes has allowed us to view garments as contextually reliant and dynamic objects that are constantly evolving and modified with everything that happens within and around them.

From the lens of the resale market, longevity is among other things a culture-, context- and user-dependent concept that relies on multiple mechanisms other than those installed in the garments. Thus, in the attempt to extend use and product lifetimes with circular business models and resale, a holistic durability concept that encapsulates the non-stable and constantly evolving genesis of garments, their users and their environments is essential.

## Acknowledgments

This paper draws on data from two pilot studies and an ongoing PhD project. The pilot studies are funded by the Innovation Network under the Danish Ministry of Higher Education *Lifestyle and Design Cluster* and ran from the Fall of 2020 and throughout 2021. The PhD project is part of the project *Blockchain, IoT and Resale* lead by Copenhagen Business School and funded by the Innovation Fund Denmark as part of the mission-based research partnership *TraCE* (trace-im4.dk) that was installed by the Danish Government in 2021.

# A qualitative framework for mapping rebound effects of different circular business model archetypes

**Ankita Das[a], Nancy Bocken[a], Jan Konietzko[a]**
a) Maastricht Sustainability Institute, School of Business and Economics, Maastricht University, Tapijn 11 Building D, P.O. Box 616, 6200 MD Maastricht, The Netherlands.

**Keywords**: Circular Business Models; Circular Economy; Rebound Effects; Circular Economy Rebounds; Business Model Experimentation.

**Abstract**: Circular business models have gained popularity in recent years due to their perceived environmental benefits. However, they can have unintended negative environmental impacts that might undermine their intended positive ones. For example, customers might buy more clothes on a second-hand clothing exchange platform, assuming it is sustainable, potentially causing negative environmental rebound effects. While the concept of rebound effects is not new, research on how they affect circular business models is still limited. Companies are increasingly experimenting with new circular business model ideas. Yet, professionals tend to use rules of thumb to determine the environmental impact of these business models due to high uncertainty during the experimentation phase. This can lead to inaccurate forecasts, with no net environmental benefit or at times even worse outcomes (backfire effects). There is a need to categorise rebound effects of different circular business model archetypes so that they can be mitigated from the outset. In this study, we propose a qualitative framework that maps circular rebound effects for different circular business models, based on a detailed review of empirical academic studies. The framework can help practitioners to be well informed while making decisions about which circular strategies to pursue while in the experimentation phase. The study aims to scope out a relatively unexplored field in circular business model literature, and to help practitioners avoid common pitfalls and mistakes in the crucial experimentation stage where impact can get locked in.

## Background

The plethora of unsustainable business models across different sectors from food to clothing and finance, has given rise to sustainable business model responses, most notably the 'circular business model' (Urbinati et al., 2017). A circular business model sets out to slow, close, narrow and regenerate resource flows (Bocken & Geradts, 2022; Konietzko et al., 2020). Yet previous work has suggested that the interpretation of circular economy in business often narrowly focuses on recycling (Allwood, 2014). Furthermore, circular business models need to be designed as such to achieve the desired results to avoid negative rebound effects (Figge & Thorpe, 2019). To illustrate, knowing that a product is made of recycled materials or secondhand, consumers might replace these more quickly (Catlin & Wang, 2013).

The first problem with well-intended sustainable and circular business models is that their impact is only measured by business on a cursory level, if measured at all (Das et al., 2022). Second, companies typically experiment to develop desirable, feasible and viable business models (Baldassarre et al., 2020), but circularity appears to be an under-explored area still (Bocken et al., 2021). This means that circular business models might be developed with good intent, but that the actual environmental impacts and worse, negative rebound effects, remain unaccounted for.

The phenomenon of rebound effects is not new with origins in energy economics literature in the 1860s when it was first called the Jevon’s paradox (Jevons, 1866). More recently, the topic has been explored in the context of circular economy by Zink & Geyer (2017), Figge & Thorpe (2019), Castro et al. (2022), Metic & Pigosso (2022), and Zerbino (2022). Zink & Geyer (2017) were the first to help understand the circular economy rebound effects, by classifying them based on direct, indirect, system-wide, and transformational effects. Castro et al. (2022) and Metic & Pigosso (2022) have gone a step further in identifying existing research gaps and establishing a research agenda in this field. And most recently, Zerbino (2022) has contributed a conceptual methodology to manage circular rebound effects, including anticipating them, monitoring impact, designing policies, and engaging stakeholders.

While there is increasing research on this topic, the awareness around rebound effects among businesses is quite low at present. However, if companies do not account for rebound effects when designing and implementing their circular business models, they risk not achieving their intended environmental goals and targets at all, specifically when accounting for their upstream (e.g., logistics, raw material sourcing) and downstream impacts (consumer behavior). This can have serious consequences down the line with anti-greenwashing laws and environmental impact reporting laws, that could potentially see companies penalized for misreporting of environmental outcomes. Additionally, companies that take a proactive approach to addressing their rebound effects early on in the experimentation phase, may also gain a competitive advantage in the marketplace, by demonstrating their commitment to sustainability and advancing their environmental agenda (Schaltegger et al., 2012)

In light of these recent developments in the field of sustainable and circular business models, and the increasing levels of experimentation by business in practice (Bocken & Geradts, 2022), this study focuses on categorizing important rebound effects of circular business model archetypes. This could help companies in having a better understanding of the true environmental impact potential and associated rebound effects of their new business idea, in the experimentation phase. This could be a step further towards mitigating them when (re)designing circular business models. We aim to answer the following research question: what are the typical rebound effects of circular business models?

## Method

This paper follows a systematic literature review approach (Bryman & Bell, 2011; Tranfield et al., 2003) to identify empirical studies of rebound effects for circular business models, with the aim to develop an emerging 'circular rebound framework' for future research.

### *Data Collection*

Data collection was done by searching Scopus and Web of Science using two search strings in order to be comprehensive. The search was further refined by research areas to exclude articles from research areas deemed to be irrelevant to circular economy (e.g., biomedical sciences). The detailed research protocol is described in Table 1.

| Research Protocol | Description |
|---|---|
| Search string #1 | ("circular economy" OR "circular*" OR "circular business*" OR "sustainable business*") AND ("rebound effect*" OR "rebound*" OR "unintended consequence*" OR "backfire effect*" OR "take-back effect*" OR "spillover effect*" OR "indirect effect*" OR "secondary effect*") |
| Search string #2 | ("circular economy" OR "circular*" OR "circular business model*" OR "sustainab*" OR "business model*" OR "business*") AND ("rebound effect*" OR "rebound*" OR "unintended consequence*" OR "backfire effect*" OR "take-back effect*" OR "spillover effect*" OR "indirect effect*" OR "secondary effect*") AND ("environment* impact*") |
| Refined by Research Areas | Engineering, Environmental Sciences, Ecology, Science Technology, Business Economics, Materials Science, Energy Fuels, Public Environmental Occupational Health, Biodiversity Conservation, Behavioral Sciences, Social Issues, Psychology, Automation Control Systems, Public Administration, Transportation, Communication, Education Educational Research, Telecommunications, History, Philosophy of Science, International Relations, Philosophy, Urban Studies |
| Scan of | Title, Abstract, Keywords |

**Table 1. Literature Search Protocol.**

The search included all articles, conference papers, and book chapters that were published on the topic until 1st February 2023 in the English language. The search resulted in 669 results from Scopus and 678 from WoS, with a total of 1347 articles. The list was scanned for duplicates (499) and resulted in a final of 848 articles.

The titles and abstracts of the articles were then scanned for relevance. The inclusion criterion was that the articles needed to clearly measure and identify rebound effects of circular business models through quantitative methods. This resulted in 56 articles being selected for a full reading. Four articles were also identified through snowball sampling. The full reading phase resulted in 27 articles being rejected. As a result, a final total of 33 articles were reviewed for this study. The process is described in detail in Figure 1.

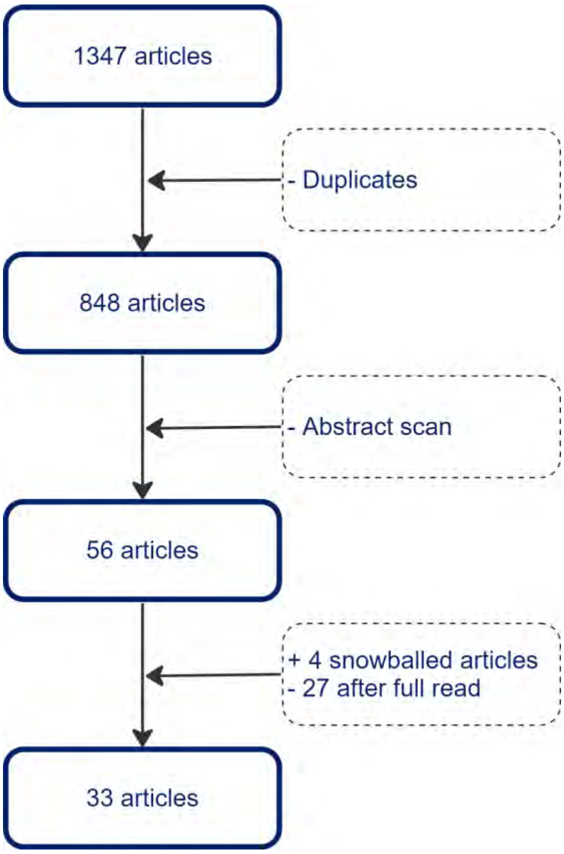

**Figure 1. Literature Review Process.**

*Data Analysis*

These final articles were then reviewed and analysed through coding in Excel for characteristics such as country focus, sector focus, data analysis methodology employed, core circular business model strategy, and rebound effects reported. The circular business model archetype typology proposed by Pieroni et al. (2020) was used for classification in the emerging framework (Table 2). These broad archetypes were: Dematerialized or Efficiency, Collaborative Consumption, product-Service Systems, Long Life, Next Life, Circular Production and Distribution, and Circular Sourcing. The codes on the rebound effects recorded were further refined based on the systematic qualitative coding protocol described by Patten & Newhart (2017). This meant that first, open coding was done to identify the prominent rebound effects, these were then consolidated through core coding into the broader categories presented in Table 2.

## Results

This study reviewed 33 articles from 2002 to 2023. The oldest article was Fons et al. (2003) on industrial symbiosis, the most recent one was Meshulam et al. (2023) on a peer-to-peer food-sharing platform. The top sectors for which rebound effects were reported were mobility, electronics and clothing/textile. The circular business model archetypes with the most empirical research on rebound effects was *Circular Production and Distribution*, with 10 articles. The least explored archetypes in research were '*Dematerialized or Sufficiency*', and *'Long life'*. Unsurprisingly, the most common rebound effect described was increase in consumption based on consumer's perceptions that the product or service in consideration is a 'greener' alternative. Table 2 lists the rebound effects observed for the different circular business model archetypes.

| Circular Business Model Archetypes | Rebound Effects | Sources |
|---|---|---|
| Dematerialised or Sufficiency (E.g., Dematerialised services, Demand reduction services, Encourage sufficiency) | - Increased exports to other markets with less environmental awareness to make up for reduced consumption.<br>- Re-spending (of time, money and energy) by consumers in other areas due to economic savings | (Grabs, 2015; Tukker et al., 2011) |
| Collaborative Consumption (E.g., Sharing economy, Co-access, Co-ownership) | - Increased logistics (and subsequently related energy and financial costs) required to maintain sharing services.<br>- Increased cleaning costs in terms of heat, water, energy, etc.<br>- In the case of car sharing, modal shift away from previously environmentally friendly activities such as biking, public transport, and walking.<br>- Increase in consumption due to improved accessibility of products. | (Amatuni et al., 2020; Levänen et al., 2021; Medina-Tapia & Robusté, 2018; Meshulam et al., n.d.; Realini et al., 2021; Vélez, 2023; Warmington-Lundström & Laurenti, 2020) |
| Product-Service Systems (E.g., Product-as-a-service, Rental, Hire, Leasing, Pay-per-use, functional sales) | - Increased logistics (and subsequently related energy and financial costs) required to maintain sharing services.<br>- Increased cleaning costs in terms of heat, water, energy, etc. | (Bridgens et al., 2019; Johnson & Plepys, 2021; Vélez, 2023) |
| Long Life (E.g., Long life products, Products with life extension services, Reduce, Repair, Modular design, Refill, Upgrading) | - Increased energy and raw material use in product life extension services.<br>- In the case of modularity, could encourage replacement leading to higher rate of upgrade than conventional products. Also, a more complex design can mean the product does not work as intended.<br>- If product is replaced earlier rather than repaired, then the value is lost<br>- Potential for overproduction of components to keep in sync with demand could increase impact. | (Levänen et al., 2021; Proske & Jaeger-Erben, 2019) |
| Next Life (E.g., Direct reuse, Next life sales, Product transformation, Refurbish, Remanufacture, Incentivised return & reuse, Recycling, Waste Management) | - High energy use in manufacturing.<br>- Imperfect substitution of primary materials with secondary materials.<br>- Increased $CO_2$ emissions if recycling rate is slow and inefficient.<br>- Remanufacturing may prolong the life of outdated technologies that are more polluting (for e.g., old car engines or refrigerators). | (Catlin & Wang, 2013; Levänen et al., 2021; Makov & Font Vivanco, 2018; Morimoto et al., 2021; Siderius & Poldner, 2021; Wiprächtiger et al., 2022; Zhang & Chen, 2015) |
| Circular Sourcing (E.g., Source circular supplies, Industrial Symbiosis, Renewable energy, Using bio-materials) | - Increased consumption based on the assumption of products being 'greener' alternatives.<br>- Increased food spoilage rates in plant-based packaging compared to conventional plastic packaging. | (Fons et al., 2003; Gerassimidou et al., 2021; Heller et al., 2019; Hutchings et al., 2021; Siderius & Poldner, 2021) |
| Circular Production & Distribution (E.g., Take-back & reprocessing used products, Cleaner production, Eco-efficiency, Energy efficiency, On demand production) | - Re-spending (of time, money and energy) by consumers in other areas due to economic savings<br>- Adopting new technologies may lead to increased waste and shorter product life times.<br>- New innovations cannibalizing existing environmentally friendly alternatives<br>- Reduced consumption may lead to increased exports to markets with less environmental awareness. | (Albizzati et al., 2022; Conte et al., 2015; Dzombak et al., 2019; Font Vivanco et al., 2014; Joyce et al., 2019; Kagawa et al., 2013; Naumov et al., 2020; Spielmann et al., 2008; Walzberg et al., 2020; Wiprächtiger et al., 2022) |

**Table 2. Framework of rebound effects observed in different circular business model archetypes (based on circular business model archetypes by Pieroni et al. (2020)).**

## Discussion & Conclusion

Past research on this topic has provided general classifications of rebound effects in the circular economy (Castro et al., 2022; Zink & Geyer, 2017). This paper takes it a step further by providing a classification of rebound effects for specific circular business model archetypes. These findings can act as a starting point for research and practice on designing truly sustainable circular business models. Further, awareness in business of rebound effects is limited as of now. And so, another aim of this framework is educational, in order to make the concept of circular rebound effects more accessible to business practitioners. Accessible information about circular rebound effects in the early experimentation stages is important for practitioners as otherwise they can lead to poor business outcomes, such as lower profits or damage to the company's reputation. The proposed framework could allow companies to make more informed business decisions, and to pivot away as necessary from a proposed pilot idea that might not give enough environmental savings, or even has backfire effects. This can ensure that good intentions also become impactful.

While we found several possible rebounds from circular business models in the literature, only some can be directly mitigated by businesses. For example, a potential rebound effect of remanufacturing, is lifetime extension of outdated, more polluting technologies, such as old car engines or old refrigerators. This could be mitigated easily through rigorous monitoring to phase out product components that are deemed harmful (Zerbino, 2022). However, it can be argued that others like indirect or system-wide rebound effects (Zink & Geyer, 2017) might be beyond the direct influence of companies. For example, re-spending of time, money and energy by consumers in other areas due to savings from efficiency, can only be somewhat influenced by companies if they employ awareness and/or sufficiency marketing campaigns, and requires more societal or policy level interventions.

Future research can look at improving this framework further by exploring mitigation strategies for the rebound effects that are in this direct zone of influence of companies.

## Acknowledgments

This work is part of the Circular X project and has received funding from the European Union's Horizon 2020 European Research Council (ERC) funding scheme under grant agreement number 850159.

# Exploring paradoxes to scaling circular business models in cascading systems in the textile and clothing industry

**Mohammadreza Dehghannejad**[(a)], **Rudrajeet Pal**[(a,b)]
a) Swedish School of Textiles, Department of Business Administration and Textile Management, University of Borås, Sweden
b) Faculty of Engineering and Sustainable Development, University of Gävle, Sweden

**Keywords**: Circular Business Model; Cascading; Scaling; Paradox Theory; Textile and Clothing.

**Abstract**: To achieve the ultimate potential of circular economy (CE), cascading plural circular business models (CBMs) can essentially slow down, narrow, and close resource loops while simultaneously achieving long-life products. Operating in cascades, however, organizations face many paradoxical tensions (PTs) due to different goals, designs, and resource requirements, as well as demands for new and unusual collaborations. Having a narrative literature review, 7 categories of PTs that could hinder scaling CBMs in cascaded systems in the textile and clothing (T&C) industry were identified. Conducting 20 semi-structured interviews with European brands/retailers, charities (secondhand stores), sorters, and recyclers who operate in cascading, this paper has contextualized four paradox classes (organizing, performing, belonging, and learning) of Smith and Lewis's (2011) paradox theory framework along those 7 categories; while mostly classified as organizing and performing, categories 5 (between circular supply structure and governance alternatives) and 1 (between scale and scope) are reported as the most prominent among T&C actors, respectively. Although those prominent categories can directly hinder the scalability of cascading CBMs, those that appeared internally and were associated with a particular CBM could indirectly affect scaling.

## Introduction

Circular Economy (CE) aims at reducing the consumption of raw materials and eliminating waste through the optimization of resource usage by circulating products and materials (De Angelis, 2021; Hopkinson et al., 2018). For its implementation, CE strategies require attention by businesses and consumers across the value chain, in order to preserve the product-material quality (and value) in the highest form. In this context, the sequential use of product-material combinations, termed cascading (Campbell-Johnston et al., 2020), can transform the value proposition and lead to sustainable product offerings. Cascading helps the sequential use of resources before ending in energy recovery and has often conflated with the concepts of recycling or down-cycling (ibid.). However, in order to achieve the ultimate potential of CE, cascading of plural circular business models (CBMs), not only at the end of the resource cycle, but in conjunction with the product use cycle, can essentially lead to slowing, narrowing, and closing the resource loops and simultaneously achieve long-life products.

Extant literature (e.g., Bressanelli et al., 2018; De Angelis, 2021; Lüdeke-Freund et al., 2018) argue that while operating in cascades, companies might encounter many challenges such as those associated with quality, quantity, and timing, when redesigning their supply chains but at the same time demand forming new, unusual collaborations. In a similar vein, Campbell-Johnston et al. (2020) point out the relative dearth of literature regarding examining how such cascading can be operationalized within the frame of CE. Drawing upon this gap, our paper postulates that such integration of CBMs into cascades demands alignment of inter- and intra-organizational processes, which can as well result in certain "conflicts". Unmanaged, such "conflicts" can eventually hinder cascading (i.e., scaling the entire system) respective scaling of individual CBMs. We draw upon some examples to illustrate this; Daddi et al. (2019) highlight such a "conflict", while using recycled materials promises environmental commitment, loss of competition due to the low quality of the products might appear. Similarly, while extending the life of products preserve material resources, it might not be accepted as new products can be more energy-efficient (Prendeville et al., 2017). From a theoretical standpoint, Smith and Lewis (2011) call such "conflicts" *paradoxical tensions* (PTs), given that these arise between different alternatives of organizational processes, structures, and goals, yet are interrelated and persist over time.

One of the industries where cascading is prominently observed is the textile and clothing (T&C) industry. In general, the T&C industry has been looking for "added value" creation through the implementation of CE principles, for a long time (Salmi & Kaipia, 2022), by operating different CBMs such as repair, reuse, sharing platforms, refurbish, recycle, down-cycle, etc. This also provides a scope for the emergence of several PTs at the level of resource needs, designs, and goals which can further hinder scaling. For instance, while having a design for longevity and higher durability of products is preferred for upscaling inner circular loops such as sharing or product-service-system (Pal et al., 2019), a design for mono materiality fits the scaling recycling CBMs (outer loop). Such PTs can also become even more prominent if different types of CBMs work together in a cascading system (Campbell-Johnston et al., 2020).

In light of this argument, the purpose of this paper is ***to explore the main paradoxical tensions that hinder scaling CBMs in cascaded systems in the T&C industry.*** De Angelis et al. (2018) argue that multiple value creation of CBMs, and the inherent complexity of CBM innovation, lead to the emergence of PTs in this context. To offer a framework of PTs in the context of CE implementation, this paper uses Smith and Lewis's (2011) typology of paradox classes. Therefore, the next section continues with framing the literature followed by the methodology and data handling. We discuss the results in the last section and conclude with remarks.

## Literature framework

### *Paradox theory*

This paper uses the paradox lens of Smith and Lewis (2011) to highlight the organizational PTs that can arise due to the implementation of CE principles. Smith and Lewis (2011) define PTs "*as contradictory yet interrelated elements that exist simultaneously and persist over time*" (p. 382). These PTs are nested at single organizational levels but also cascade across levels, where a PT at one level can lead to a PT at another (ibid.). PTs can exist both inherently within the system (latent) or be constructed socially through organizational players' cognition (salient). Either way, they are juxtaposed through environmental conditions (ibid.). As it is stated, in order to respond to the divergent demands and meet long-term sustainability, continuous efforts are needed to identify and live with PTs, rather than being selected to achieve short-term performance (ibid.). In other words, since contradictions are placed at the heart of the PTs, they should be embraced, rather than resolved. Therefore, their elements will remain in place to be managed continuously as their relationships are contradictory at times (Huerta Morales, 2020).

Smith and Lewis (2011) have defined four PT classes as organizing, performing, learning, and belonging. Organizing classes arise from organizations' leadership and structure, design, and competitive processes leading to the tensions between routine and change, competition and cooperation, as well as empowerment and control. Performing classes appear due to the existence of conflicting goals between the demands of internal and external stakeholders. Change in dynamic systems leads to learning classes; attempts to destroy the past to create the future, such as the tension between incremental and radical innovation. Finally, belonging classes or tensions of identity surface due to the complexity and multiplicity between individuals and groups that follow both differentiation and homogeneity. Besides those four classes, PTs can surface as inter-class such as organizing-learning, performing-belonging, learning-performing, etc. For example, a learning-organizing class indicates organizations that pursue focus and efficiency while changing and being agile (ibid.).

*PTs within cascaded systems of CBMs*

Regulatory, technological, and cultural PTs along with the ones experienced in the market and organization, are among those derived from the transition toward the CE principles (De Angelis, 2021). These PTs are often classified at the micro, meso, and macro levels, and thus, need to be analyzed more from a business model perspective in order to know how to create added value and make a competitive advantage (ibid.). Thus, a cascaded system is essential not just for the scaling of each CBM, but rather for operationalizing scale across different single CBMs to deliver transformational value propositions (Franco, 2019). Optimizing performance, product longevity, and raising resource effectiveness are the core of the cascading system to get multiple CBMs linked in resource loops for material/product circulation (De Angelis et al., 2018). In other words, cascading can prevent value loss and strengthen the expansion of the inner loop through more collaboration in a value chain, including different actors such as suppliers and designers. De Angelis (2021) also points out that the circulation of longer and net inputs is possible through more business model integration.

Studies conducted in the field of CE, indicate PTs in different industries. In terms of attaining scale, Bressanelli et al. (2018) have explored PTs between upgradability versus longevity. Referring to home appliances, they point out that products designed to last longer cannot participate in the processes of continuous technology improvements. For example, extending the life of a washing machine can lead to a loss of the chance to participate in the continuous increase in energy or water efficiency offered by new models. PTs between reverse supply chain disposition choices (e.g., refurbishing versus recycling) due to the potential loss of value of electronic devices, used computers, and mobile phones are also reported by Huerta Morales (2020).

In the T&C industry, Daddi et al. (2019) have identified tensions between eco-friendly solutions such as the use of recycled material versus customer value and compliance, for making substitution choices. As they point out, producing clothes from recycled materials and by-products, although can address environmental concerns, threaten organizational managers at the risk of losing competitiveness due to the loss of brand credibility. Another example refers to PTs between different CE loops to attain scale in the same industry; while from a design and durability point of view, keeping garments' combinations can increase product quality and lifetime (Pal et al., 2019), recyclability and calling for mono-materiality are needed to close the loop (Sandvik & Stubbs, 2019).

As stated before, PTs can appear latently and saliently (Smith & Lewis, 2011), while more distinguishable in the linear value chains due to less complexity, they might not be easily discoverable when it comes to the cascading system, especially when cascading takes place within inter- and intra-organizational relationships. Based on this notion and to categorize PTs, which we will discuss later in the methodology section, this study has identified 7 categories of PTs given a narrative literature review as follows (Figure 1).

| No. | Paradox categories | Contextualization | Derived from |
|---|---|---|---|
| 1 | Between scale and scope | Economies of scale through standardized routines (reducing total costs as well as increasing productivity) versus economies of scope through customization and upgradability (involving initiatives to create business opportunities as well as producing high-value products). | Bressanelli et al. (2018), Sandvik and Stubbs (2019), Huerta Morales (2020), De Angelis (2021) |
| 2 | Between different CE loops | Having iterations between different loops for enabling the circulation of materials/products and closing the loop versus slowing and narrowing the loops by producing long-lasting products. | Prendeville et al. (2017), Sandvik and Stubbs (2019), Kühl et al. (2022) |
| 3 | Between reverse supply chain disposition choices | Having loops where the product can be used in cascade, but because of the potential loss of materials/products value, the wrong loop is selected or even some loops are ignored. | Huerta Morales (2020), Kühl et al. (2022) |
| 4 | For making substitution choices | Choosing an alternative to have a product or service but replacing the original desire in order to satisfy some demand, especially when it comes to market competitiveness or customer reaction. | Bressanelli et al. (2018), Daddi et al. (2019) |
| 5 | Between circular supply structure and governance alternatives | Choosing different types of structures and governance (being decentralized and collaborative to have more flexibility and resiliency to meet the needs of stakeholders versus being centralized and controlling to have a core competency). | Bressanelli et al. (2018), De Angelis (2021), Jensen et al. (2022) |
| 6 | Between the influence of regulatory instrument alternatives | Having global regulations (e.g., to control the flow of materials and waste to ensure safety) versus liberal regulations (from which innovation can emerge). | Tong et al. (2018), Daddi et al. (2019), Johansson (2022) |
| 7 | In terms of organizational mindsets and innovation paths | Simultaneous attention to customer requests and established organizational technological standards (each requires its own interactions). | Muñoz and Cohen (2017), van Bruggen et al. (2022) |

**Figure 1. Categories of paradoxical tensions based on the extant literature.**

Smith and Lewis (2011) note that living with PTs helps actors to depart from linearity and rationality, by putting the puzzle pieces together. In other words, this is through this paradoxical thinking that is possible to reduce ambiguity and manage the complexity of sustainability issues (van Bommel, 2018). CE covers multiple production and consumption strategies operating at different scales of upcycling and downcycling stages that can be used to valorize the process of specific materials (Campbell-Johnston et al., 2020). Since the T&C industry is controversial, implementing the CE, by designing products with sustainable inputs as well as cascading can depend on how PTs are addressed (Daddi et al., 2019).

## Methodology

To address the purpose, a narrative literature review is done through a database search (on Scopus, Web of Science, ABI/INFORM Collection, ProQuest One Business, and Business Source Premier). We scanned different industries such as T&C, furniture, automotive, food, construction, wood, etc. since macro-level transformation in the T&C industry needs identifying key paradoxes. We also looked beyond the *paradox* and *CE* as keywords since a paradox could be often implicit and, in many papers, either used reciprocally or mis-connoted as dilemma, barrier, or challenge. Overall, 7 categories of PTs were revealed after screening the final literature list and removing overlapping similarities (Figure 1).

Having purposive sampling enabled this study to include different sets of European T&C actors who operate with CBMs in the cascading system. Reviewing their CE initiatives and collaboration in various CE loops, they were asked who would be most suitable for the topic under study by sending them an email explaining the full purpose of the research. By simplifying the questionnaire, 20 online-based semi-structured interviews (about 1 hour each) were conducted with 3 Swedish brands/retailers, 8 charities (including 7 Swedish and 1 Norwegian), 8 sorters (including 2 Dutch, 2 German, 1 Polish, 1 Swiss, and 2 Swedish that one of which is non-profit), and finally, 1 Swedish recycler.

Due to the implicit understanding of PTs, we took a step back by sending the questionnaire offline a few days before the interviews, asking respondents to reflect on the 7 paradox categories. In conducting the interviews, we also used various examples of PTs obtained from the literature review to make them clearer to respondents. Voluntary participation and recording of the interviews are done following GDPR, and respondents were assured that the results will be reported anonymously. Transcribing interviews, using Excel and Word, results are discussed in the next section.

## Discussion and conclusion

Figure 2 shows the matrix of 7 categories and 4 classes of PTs of Smith and Lewis (2011), and maps the organizations from which these PTs are evident. As can be seen, all seven categories of PTs that were identified through the literature are present among the T&C actors having CBMs; though most common are those related to organizing and performing classes, while belonging and learning class PTs were less noticeable. Out of 7 categories, our analysis reveals that categories 5 (between circular supply structure and governance alternatives) and 1 (between scale and scope) are the most prominent ones. In addition, T&C actors have experienced inter-class PTs such as organizing-learning, performing-belonging, etc.

<table>
<tr><th>Categories</th><th>Learning Class</th><th>Belonging Class</th><th>Organizing Class</th><th>Performing Class</th></tr>
<tr><td rowspan="3">1</td><td></td><td rowspan="2"></td><td>Charity 2; Brand/Retailer 2; Recycler 1; Sorter 5</td><td rowspan="3">Sorter 7; Brand/Retailer 3</td></tr>
<tr><td>Charity 7*</td><td>Charity 7*</td></tr>
<tr><td></td><td colspan="2">Charity 2</td></tr>
<tr><td>2</td><td></td><td>Brand/Retailer 3*</td><td></td><td>Brand/Retailer 3*</td></tr>
<tr><td>3</td><td></td><td></td><td>Charity 6; Sorter 6</td><td>Charity 2</td></tr>
<tr><td>4</td><td></td><td></td><td>Charity 6; Sorter 6</td><td>Charity 2</td></tr>
<tr><td rowspan="3">5</td><td rowspan="3"></td><td rowspan="2">Charity 2</td><td>Charity 2; Charity 3; Brand/Retailer 1; Brand/Retailer 2; Charity 4; Sorter 2; Recycler 1; Sorter 3 (Non-profit); Brand/Retailer 3</td><td>Sorter 1; Sorter 5; Sorter 6; Sorter 7; Brand/Retailer 3</td></tr>
<tr><td colspan="2">Recycler 1; Brand/Retailer 3</td></tr>
<tr><td colspan="2">Charity 8</td><td></td></tr>
<tr><td>6</td><td>Charity 4</td><td colspan="2">Charity 4</td><td>Charity 1; Charity 4; Sorter 8</td></tr>
<tr><td>7</td><td></td><td>Charity 5</td><td>Brand/Retailer 1; Sorter 8</td><td>Charity 2; Charity 7; Sorter 4</td></tr>
<tr><td colspan="5">* Inter-class</td></tr>
</table>

**Figure 2. Distribution of T&C actors based on paradox classes along the 7 categories.**

It is evident that all 7 categories yield performing PTs. As an example, and in relation to category 5, sorters point to the paradox of economic versus environmental goals (Smith & Lewis, 2011) in selecting between a local but costly supply chain and a global one with a larger environmental footprint. Performing paradox has also appeared latently, hindering cascading flow. Referring to category 3, a charity (secondhand store) states that brands/retailers tend to recycle rather than reuse to protect their brand reputation as well as for the sake of fast fashion.

As mentioned, organizing PTs are highlighted more in relation to category 5, arising in terms of supply chain design, such as between global and local organizations, or process centralization versus decentralization (De Angelis, 2021). This sometimes leads to category 1 tension, since working in a centralized way increases scale but limits room for creativity (e.g., scope). For scaling, some sorters strongly believe in working globally, even though the exportation of post-consumer clothes faces tighter restrictions due to the upcoming EU regulations for reducing transportation. Apart from that, tax issues due to the organizational structure of some charities (who are capable of improving new CBMs such as repairing and refurbishing), along with the need for education and training, understanding customer expectations, and target groups hinder cascading scalability. The current example not only reflects the organizing class (creativity versus exploiting existing ways of working), but also indicates the learning paradox. As Smith and Lewis (2011) state, the learning-organizing paradox is prominent in organizations that pursue efficiency while changing and being agile.

Belonging PTs or tensions of identity (Smith & Lewis, 2011) are also seen in the form of competing values, roles, and memberships as well as value for individual players or for the whole circular ecosystem. In relation to category 7, as an example, Charity 5 points to the internal clash between different managerial tiers in terms of prioritizing between social and customer values.

To conclude, while the most prominent categories can directly hinder the scalability of cascading CBMs, other PTs, such as the ones that appear latently, and especially the latter example (surfacing clash between different managerial tiers) that is internal to a single CBM, can indirectly hinder cascading.

Further research is needed to rank PTs in order to get addressed based on the higher priorities.

## Acknowledgments

We would like to acknowledge FORMAS, The Swedish government research council for sustainable development, under grant number 2021-00529, for funding this study.

# Repairing reality: from artificial biomechanics devices to bio-inspired fixing kit for existing conventional products

**Julia Bonilla Domínguez** [(a)], **Jorge Sierra-Pérez** [(a)], **Laura Talens Peiró** [(b)]
a) Universidad de Zaragoza: Escuela de Ingeniería y Arquitectura, Zaragoza, España b) Sostenipra (2017SGR1683), Institut de Ciència i Tecnologia Ambientals (ICTA-UAB), Universitat Autònoma de Barcelona (Unitat Excelencia Maria de Maetzu MDM CEX2019-000940-M), 08193 Cerdanyola del Vallès, Barcelona, Spain

**Keywords**: Repair; Bio-inspiration; Product Design; Furniture; Do-it-yourself.

**Abstract**: Repair is one of the powerful strategies to keep the value of the already existing products longer in society. Currently, advances in manufacturing technologies and material properties have not resulted in consumer products with more durable lifetimes and design features that promote this. Unexpectedly, other scientific areas such as biomechanics have developed artificial devices as prosthesis that can serve as inspiration to propose new repair solutions to extend the lifetime products and prevent waste. This study builds on bioinspiration to develop newer devices for the repair of conventional household products as furniture, using as case study the breaking of chair legs. The association between a chair leg and a limb of the human body has facilitated this association of ideas and following a product design method an adaptation of repair methods from the medical area to the furniture sector is proposed. Existing splints for the immobilisation of limbs, orthopedic legs or hip prostheses has been used to develop a first prototype of a one-self repair kit. The repair kit includes the fixing device and also a full set of supporting information to allow users without any previous knowledge from the Do-It-Yourself approach. The aim of the resulting one-self repair kit is two-fold. First, to motivate users to repair simple products in an independent way and to promote responsible consumer behaviour over time. Second, the progressive acquisition of technical skills increases their level of expertise in repairing products which makes consumers feel contributors to advancing towards longer lasting products.

## Introduction

The European Commission (EC) defines a circular economy (CE) as one that aims to keep the value of products and materials as long as possible in the value chain and minimize waste generation (European Commission, n.d.). This means that products shall be designed for longer lifespans and that the waste generated shall be converted into secondary resources to be used again in the production of new products and services. Therefore, CE can refer to the repairability of products, the recycling of materials or the development of new business models based on services. This paper proposes a kit to perform a **product repairability.** This idea is tested as an enhancer of creating new business models that enable the repair of products and materials, and that foster collaboration and cooperation between the different actors in the value chain. The development of the repairability kit also aims to raise awareness on product lifetimes and engage consumers towards a more sustainable consumption. It is important to promote the 'Right to repair' and to empower consumers towards waste reduction by repairing and reusing their products. **One-self repair** can be particularly important in the context of CE, as it can help extend the life of consumer products, thus reducing the waste and environmental impact associated with the production of new products (Talens Peiro et al., 2022). Facilitating the repair of consumer products, the need to extract new materials is reduced, and thus the amount of waste associated.

In this regard, EC has started to work on the *Ecodesign for Sustainable Products Regulation* (European Commission, 2023). This proposal is the cornerstone of the EC's approach to designing more sustainable products. It builds on the existing Ecodesign Directive (European Commission, 2009), which currently only covers energy-related products. As shown in Figure 1, among the products with the highest priority to regulate from an environmental standpoint are: textiles and footwear, furniture, Ceramic products, or Tyres.

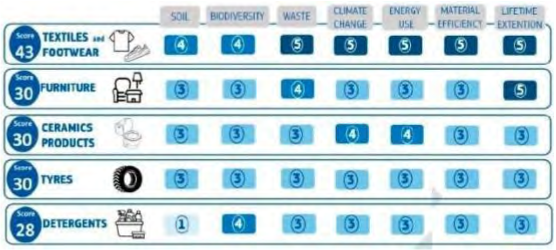

**Figure 1. Environmental assessment of the 12 end-use products shortlisted (European Commission, 2023).**

**Furniture** presents one of the products with the highest environmental improvement potential in terms of waste reduction and lifetime extension. There is therefore great potential for the application of circular design strategies: design for durability, design for disassembly, design for refurbishing and recyclability, improving the availability of spare parts and a minimum recycled content material. The availability of replacement parts in a product is one key aspect affecting all impact categories. In the case of conventional household products as furniture, there are other proposed requirements:

- Performance requirement on design to facilitate reuse, repair, refurbishing and recycling.
- Performance requirement on availability of spare parts for the product.
- Information requirement on how to repair the product to increase durability to avoid air pollution due to new products acquisition.

The transition of the furniture sector from a linear to a CE will require significant changes. The furniture sector has a lot of potential in terms of lifetime extension, but there is still a need to facilitate products that ease repairability. Today, there is also a great share of consumers with the need to renew their furniture in a short time. Some previous studies have demonstrated that product attachment is key for product retention, therefore providing kits to enhance the repair of products becomes crucial (Mugge et al., 2008; van den Berge et al., 2021). In this regard, the furniture sector has already rethought its strategies, considering some data that will allow it to offer more value to its customers, especially at the time of purchase. Within a framework of sustainability and repairability, the furniture industry is evolving into a renewal market, and this remarkable change must be considered into the design process.

## Bio-inspired design

Bio-inspired design is chosen to take its functionalities as a reference and transfer them to the product design (Bar-Cohen, 2006). The structure and function of biological systems are identified, as well as how they maintain their function through these products. Bio-inspired design offers many possibilities of innovative and sustainable products by observing and studying natural systems. The use of bioinspiration as a tool is about designing by incorporating characteristics of natural systems to improve processes and products (Forniés & Muro, 2012).

This study proposes as a necessity the repair of a chair, due to the breakage of one of its legs (or several), seeking inspiration in the human body and its limbs. The limbs of the human body are a marvel of evolutionary engineering. Each species has evolved specific limbs that allow them to adapt and survive in their natural environment. Human limbs can be damaged, and, from trauma medicine approach, different methods have been developed to replace them, mainly by using prostheses. In this regard, prostheses are taken as bioinspiration for the design of repair solutions for the case study.

Prostheses are artificial devices designed to replace or supplement a part of the body that has been lost or is not functioning properly due to injury, disease, or disability. These features are taken as inspiration to repair and fix the broken chair legs. By means of Inspiring Panels, characteristics are extracted and reflected in the concepts as shown in the following figures. Each prosthesis panel is classified according to the function of:

- Connecting parts (Figure 1)
- Fasteners parts (Figure 2)
- Replacement parts (Figure 3)

**Connecting parts**, such as those used in hip or shoulder prostheses, shown partially in the inspiring panel in Figure 2, have some similarities to the limbs of the products in terms of function and design.

In hip prostheses, the attachment piece is used to fix the prosthesis to the pelvic bone and the femoral head. This attachment piece must be carefully designed to ensure a solid and stable connection between the prosthesis and the bone, while also allowing sufficient range of motion for the wearer to move comfortably and painlessly. Similarly, in some products, limbs or components may require a connecting piece to attach them to other parts of the product. This attachment part must also be designed to provide a secure and stable connection while allowing enough range of motion.

In both cases, material selection is important to ensure the durability and strength of the mating piece. In hip replacements, materials such as titanium, which is strong and lightweight, are used, while in some products, reinforced plastics or strong metals may be used for the mating parts.

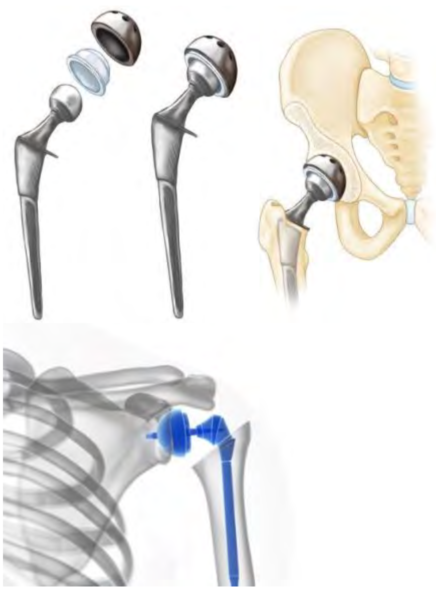

**Figure 2. Connecting parts (e.g. hip or shoulder prostheses) (https://orthoinfo.aaos.org/, https://www.institutamoros.com/).**

**Fasteners parts** are focused on 3D printed wrist splints, shown in the inspiring panel in Figure 3, used in the fabrication of customised prostheses. Wrist splints are orthopedic devices used to immobilise or stabilise the wrist in cases of injury or disease affecting the wrist joint. These splints provide a comfortable and secure fit to improve the user's mobility and quality of life. Moreover, 3D printed wrist splints can be used to hold limb products in a secure and stable position. These braces can be designed to fit the unique shape of the product and provide a personalize fit and specific position. They can be a useful tool in the holding of limbed products and in the manufacture of custom parts. The ability to customise these fasteners makes them a versatile solution for a wide range of applications.

**Figure 3. Fasteners parts (e.g. splints).**
https://www.dezeen.com
https://www.nicerapid.com

**Replacement parts**, such as prosthetic legs or feet (Figure 4), are used to replace lost or damaged limbs in humans. These prostheses can be designed to fit the specific shape and size of the user's limb. In the context of limb products, inspiration from prosthetic legs or arms can be used to design a functional and comfortable replacement part. They can be designed to match the shape and size of the product's limb, providing a secure and stable fit that allows the user to perform daily activities. These prostheses allow flexion by substituting the musculature and tendons of the foot and leg by its structure and the material used. This can provide new functionalities to the repaired product.

**Figure 4. Replacement parts (e.g prosthetic legs or arm) https://www.blatchfordmobility.com/.**

## Methodology

The product design methodology has been followed. Four phases are identified in the **design process** that allow the overall development of the project to be completed.

**Phase 1. Research:** Analysis of the current scenario of CE including the consumption-repairability relationship in furniture sectors. Moreover, existing initiatives to the implementation of repairing into the sector are identified. Finally, it has been identified significant deficiencies in the sustainability framework.

**Phase 2. Case Study:** The different types of breakages for each furniture typology are studied. The main conclusions of the Case Study are drawn, and the following phase is limited to one type of furniture, being the one with the greatest potential to be repaired (chairs).

**Phase 3. Conceptualisation:** A chair analysis focused on the main typologies of possible breakages was performed. For the Ideation phase, different Creative Techniques are used to conceptualise the ideas. These are: Bio-inspired design using Inspiring Panels (Figures 1, 2 and 3), Analogies or Mind Map, according to different functions, which are especially focused on the repair of legs, the extremity of the chair that is most frequently repaired.

**Phase 4. Final development:** During this phase, the main part of the product, as well as the rest of the elements of the repairability kit, have been formally and functionally developed. The final step was the construction of a functional prototype of the kit.

### Product design concepts

The main objective is to make a transfer from clinical products/devices to conventional domestic products. This case is related to the extremities of the chair, i.e. its legs, and how the concept of repair is applied in each type of prosthesis. Each concept focuses on a specific chair structure (morphology) and its similarities to the limbs of the human body.

*Concept 1. Connecting parts for repair chair limbs*

This concept is inspired by a shoulder prosthesis (Figure 2) and allows it to maintain the functionality of the chair repairing the broken leg. In this case, the proposed kit does not allow rotation, in accordance with its original functionality, the repaired leg remains static and well-fixed to the seat (Figure 5). It is a bio-inspired design, especially in the process of fitting the prosthesis, and in this specific case, adapted to the process of repairing the chair.

Components included in Repair Kit1:
1. Assembly piece for leg
2. Assembly piece for seat
3. Intermediate connecting piece
4. Headless bolts

**Figure 5. Repair process with connecting parts.**

*Concept 2. Fasteners parts for repair chair limbs*

The kit is bioinspired in a splint, which has modular and flexible qualities. These parts can be joined together in any direction, forming a network of the necessary size depending on the type of leg. These parts are made up of thicker main axis

Each piece incorporates some central axes, as a backbone, and together with other thinner transverse axes, as branches, can be intertwined with other pieces. A 360º net is formed that adapts and wraps around the shape of the chair leg (Figure 6). By applying heat to the netting, the fabric is shrink-sealed to the chair leg and is acquired with greater precision and strength at the junction.

Components included in Repair Kit2:
1. 3D printed flexible fabric of bio-inspired 'Sugru' material.
2. Corrugated wooden fixing dowel.

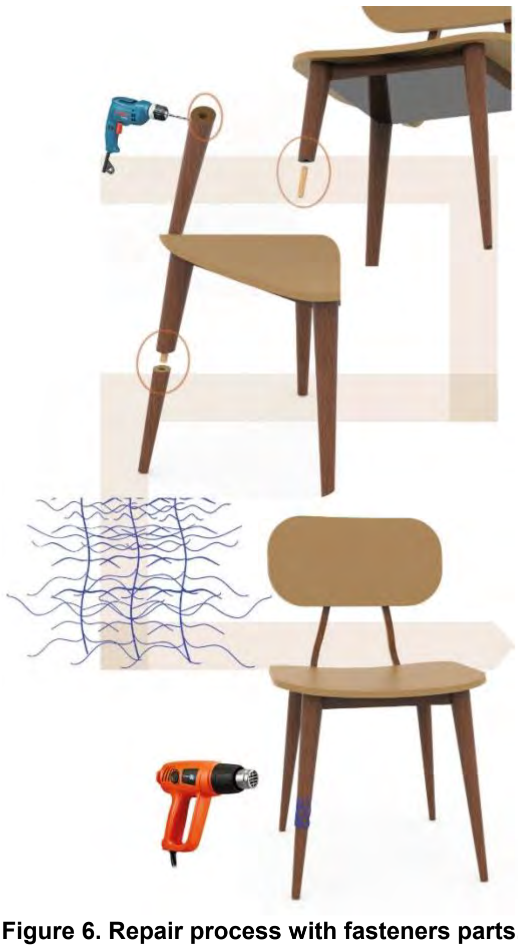

**Figure 6. Repair process with fasteners parts.**

*Concept 3. Replacement parts for repair chair limbs*

The kit proposes a bioinspired concept on leg prosthesis, which allows the replacement of the broken leg by the new one. This prosthesis has elastic and modular properties. It has a particular quality that gives the new functionality to the chair: The prosthesis of the leg has a slight flexion, i.e. can allow for balancing. In this way, the repaired chair has new functionalities. Moreover, the formal aspect can be changed to give it uniqueness, showing the emotional value and sense of belonging behind the process of repair. For optimal movement, two legs are replaced (Figure 7). Additionally, this concept can be extrapolated to other furniture products with extremities such as table, bookshelf or chest of drawers.

Components included in Repair Kit 3:

1. Bio-inspired PP bending leg prosthesis
2. Adjustable upper part
3. Reinforcing ring for hole

**Figure 7. Repair process with replacement parts.**

## Final repair-kit proposal

The approach developed previously has been focused with the aim to contribute to **sustainable development and resource efficiency**. In the case of furniture, there is a great potential to have an impact on these aspects by facilitating their lifetime extension. As furniture products are a common business to consumer products, we identified that the main motivation from the user approach is to have the 'Right to repair' using the 'Do-it-yourself' (DIY) approach. DIY should be easy, feasible and cost-effective with an investment of dedication and technique to keep furniture in the best condition.

In this sense, the proposed repair-kit is composed by an unique part that can be purchased at the same place as the chair (Concept 1). Each kit, presented in a paper bag, is designed to fix one leg (Figure 8).

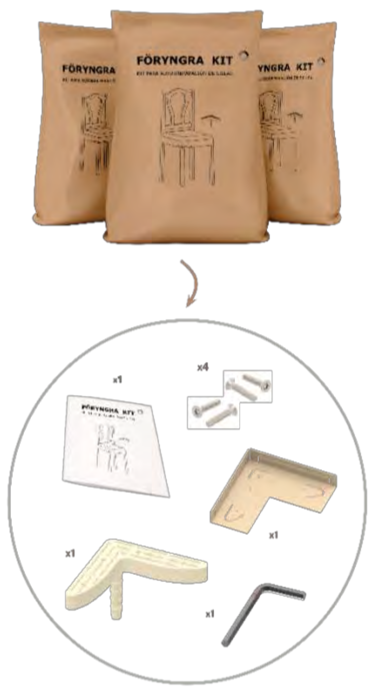

**Figure 8. Repair kit for chair leg.**

The kit includes, in addition to the "chair prosthesis", the fasteners (standard M6 screws) and tools (a standard 5 Allen key) to perform the repair. In addition, it includes an user's guide and a template to facilitate the location of fasteners in the chair during the repair process. The instructions have been designed using the assembly instructions found in conventional assembly of furniture by users. This selection was made because these instructions combine a good balance between written and illustrative information and are generally well-understood by users.

As part of the work, a prototype of the selected kit for the one-self repair of chairs was developed using 3D printing. The repair kit was afterwards tested on real chair legs. This kit is ready to be commercialized as a stand-alone product, thus, to facilitate repair and the product retention. Furthermore, this repair kit could be included as part of a furniture business model to attract and build customer loyalty.

## Discussion

This study has followed product design methods and used bio-inspired design to use know-how already available from other disciplines by applying creativity. It allowed to contribute to the broadening of the vision of this activity, and not to consider it as an ordinary process, but as a metaphor that is based on the medicine of objects. A surgical process that goes beyond functionality, but also focuses on the acceptance and visualisation of prostheses that make it possible. The selection of the discipline of traumatology is an example of how expertise can be transferred across sectors, and how repair expertise from other disciplines, in this case medicine can serve as inspiration for furniture. The current study demonstrates the benefit of addressing repair from different disciplines and sectors.

The use of this kit avoids the premature discard of the chairs and can also serve as inspiration to develop eco-design strategies using a systemic view of products. The user gets his/her chair leg repaired and rejuvenates its functionality and appearance which enables product retention. Moreover, product repair can have an emotional connection with users, whether as a form of personal satisfaction, care and preservation.

The promotion of one-self repair as a way to extend product lifetime and contribute more broadly to product sustainability and it also encourages the user to participate more actively in the knowledge and implementation of a sustainable and circular model.

# Methodology for Holistic Circular Product Creation combining Strategy Measures and Life Cycle Assessment

**Jan Druschke[(a)], Nils F. Nissen[(a)], Lutz Stobbe[(b)], Martin Schneider-Ramelow[(a,b)]**
a) Fraunhofer Institute for Reliability and Microintegration IZM, Berlin, Germany
b) Technische Universität Berlin, Berlin, Germany

**Keywords**: Electronics; Life Cycle Assessment; Priority Parts; Repair; Lifetime.

**Abstract**: Extending the use time of electronic products through repair is a cornerstone of the European Green Deal. In the majority of cases, more repair will be beneficial environmentally, because value (both economically and environmentally) is preserved, thus reducing the overall resource consumption. There are a number of obstacles to establishing, enacting and enforcing more repair through regulation or non-regulatory incentives. This paper provides a methodology combing the 5C Method, orientating life cycle assessment with subsequent ecological cost-benefit analysis and a strategic principles approach to weight up trade-offs for priority parts and entire electronic products for the circular economy.

## Introduction

The circular economy, as an economic model focuses for example reuse, repair, refurbish, and recycling in a closed circuit to preserve the utility and value from products, components, and materials. The aim of the methodology is to enable companies to develop products for the circular economy holistically. Therefore, a combined approach consisting of sustainability assessment and potential identification, circular product development and circular value creation and business development.

## Sustainability balancing and potential identification

The current proposal for a new Ecodesign for Sustainable Products Regulation builds on the existing Ecodesign Directive by the Joint Research Center and suggests a Scoring system for assessing the reparability and upgradability of generic products placed on markets. It founds on three pillars: Priority parts, Key parameters for repair and upgrade and the Scoring Framework. The priority parts, which identify at product group level to enable the comparative assessment of products, are first functionally important and second likely to fail or to be upgraded by definition. The functional importance include not only hardware but also software or firmware in particular. The most important aspect for determining priority parts, with respect to reparability issues is the frequency of failure and upgrade. Therefore, the source of information relies on manufacturers of products and parts, repairers, reuse and remanufacture organizations, consumer testing organizations, insurance companies, researchers and regulators. Priority parts are functionally relevant parts that are typically associated with at least 3% of the typical failure rates for that product group and weighting higher with an increasing rate of failure. This selection and weighting process in combination with the key parameters for disassembly to repair/upgrade the product (e.g. disassembly depth, fasteners, tools spare parts or information availability) are mandatory, considering to efficient accompany the industry on their path to circular product development. In Addition, the current proposal status provides a hybrid system with pass/fail criteria that products have to fulfil in order to be eligible for the repair/upgrade rating.

However, in order to keep into account not only functionality and failure rate, it is important to evaluate the environmental impact of these priority parts and, in addition, the overall impact of possible maintenance, replacement and repair services for the identified components.

### *5C Method as a guideline for preparing the life cycle inventory*

Life cycle inventory models can become highly complex, since the requirements often exceed a relative environmental impact of an individual technology system and the absolute environmental impact, for example a geographically and temporally defined reference area, is needed. This circumstance requires a more practical approach for an orientating environmental impact assessment, which comply to ISO14040/44, but is quicker to do and more applicable to industry needs.

The 5C Method (Stobbe et al., 2023) provide a principal structure that represents the complex, technical and application-specific interactions of a life cycle inventory model as completely as possible. The five basic building blocks (5Cs) of this methodological approach are shown in a schematic overview in Figure 1.

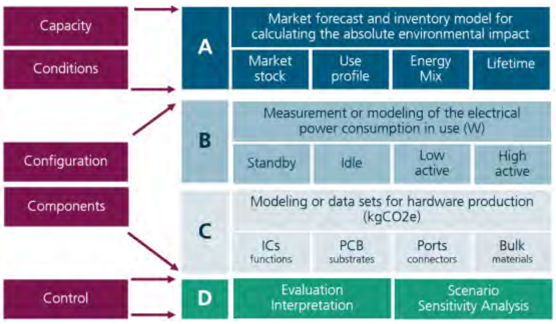

**Figure 1. 5C method for the preparation of a market-related environmental potential analysis.**

The 5C method structures the life cycle inventory based on the following five terms: Conditions, Configuration, Components, Capacity and Control.

In principle, the term "Conditions" is used to analyze the technical, geographical, economic and temporal reference object and to identify essential parameters for the creation of the inventory model. The "Configuration" models the technical structure and determines how many and which device-related components are included in the model, how they are linked and, if necessary, how the model is scaled. The term "Components" encompasses the environmentally relevant aspects of the appliance technology or its main components. The "Components"-term is interpreted flexibly in this context and can refer to an entire appliance or only one assembly. The data include, for example, the electrical power consumption in different operating conditions, power losses of amplifiers and converters in the power supply or additional energy expenditure for active cooling. For a simplified model, the type, size and material composition of the installed semiconductors, PCBs, heat sinks, connectors, cables and housings are recorded here as well. "Capacity" provides usage-related performance data, primarily depending on the technology generation, but sometimes also depending on the utilization or other usage factors. Furthermore, the usage pattern and system load is also described, as an annual electricity consumption characterize the use phase of electronics. "Control" represents factors that influence the energy demand during operation. This includes all information on individual operating states and the technical options for load-dependent energy management.

In summary, the "Conditions" determine the reference subject and operating conditions, "Configuration" the system architecture and dimensioning, "Components" the energy demand (use phase) and resource demand (production phase), "Capacity" the use profile and functional unit and "Control" the energy management and capacity utilization. This method is an appropriate approach to specify the knowledge foundation necessary for developing individual strategic measures of market participants and products.

## Trade-offs between environmental performance and repair improvement

Extending the use time of electronic products through repair and upgrade will be beneficial environmentally for a majority of electronic products through reducing the overall resource consumption. It's essential to look at the role of priority parts as a means to analyze potential trade-offs and focus reparability improvements on the most relevant areas, to achieve highest environmental gains without triggering negative side effects. Discussing the principles of priority parts and the basic trade-off constellations is an essential task for companies, as producing and storing a multitude of spare parts for a very long time is not always a net benefit for the environment. These trade-offs can only be identified and quantified by at least orientating life cycle data for the priority parts. This assessment puts the trade-offs in perspective regarding potential regulation or incentives, and in particular the right-to-repair debate. Apart from the trade-off between minimal environmental impact and availability of priority spare parts, there are other side topics such as remote or regional repair, shift of business models, non-discriminatory access to spare parts and repair procedures, and the potential role of software.

Companies need to manage these potential trade-offs efficiently through holistic design decisions (life cycle assessments) and their business model. In particular, the various aspects and characteristics of the EN 4555X series of standards for circular design, which regulate product design for the circular economy, need to be elaborated. The basic procedure for preparing a life cycle assessment according to ISO 14040/44 and its four phases - objective and scope, life cycle inventory, impact assessment and interpretation - provide support for a reliable approach. Raising companies' awareness of the required data basis and the general approach to life cycle assessment is an important task, necessary for an efficient transfer of products into the circular economy. As for every company, there might be different solution strategies within manufacturing, use phase and end-of-life depending on their products and business models. In the manufacturing phase, these are the use of used and reconditioned components, the use of (tested) recyclates and the reduction of material diversity and material composites. In the use phase, design & service for repair (modular, condition monitoring), design & service for service life extension (software updates) and design for robustness (addressing all typical failure mechanisms such as humidity, thermal and mechanical stress, etc.) should be weighed up regarding the quantified ecological efficiency. In the end-of-life phase, the focus is on non-destructive dismantling of components and assemblies for reuse as well as the design for disassembly of recycling-specific material fractions, such as iron, aluminum, copper (non-ferrous and precious metals), as well as plastics, resins and glass.

### *Orientated Life Cycle Assessment*

The starting point for all trade-off considerations should be a simplified environmental assessment (product carbon footprint) focusing production incl. raw material (primary), of the electronic components of the product. Based on the parts lists (bill of materials), data sheets, photos and technical drawings, as well as regular exchanges with companies, the Global Warming Potential (GWP) of the selected assembled PCBs (printed circuit boards) can be calculated. The goal is the exact determination of chip areas and package types and PCB determination, as experience shows that these account for the largest ecological footprint on an assembled PCB. For all other active and passive components on the PCB, applying a rule of thumb is a legit way for a quick and easy approach, as it usually requires a high workload in the assessment, but makes up a smaller amount in the overall carbon footprint. As the use of electronic components strongly influence and vary by their application, a more precise view on parts like electrolytic capacitors, connectors, antennas, cooler and housing may be necessary.

We have investigated the PCBs taking place in latest oven generations. The assembled printed circuit boards of the oven have a GWP of 32.77 $kgCO_2eq$ in manufacturing. This value is relatively low in comparison to for example modern Smartphones with approximately 45 to 90 $kgCO_2eq$. However, small devices with high computing power and more stacked IC areas threw high build-in memory capacity usually show an increased GWP value for the ICs. Due to its functioning, the oven does not need this amount of computing power and provide space for large PCB areas. Because of this circumstance, the PCBs with 20.84 $kgCO_2eq$ accounts for 63.6% of the manufacturing GWP, as shown in Figure 2.

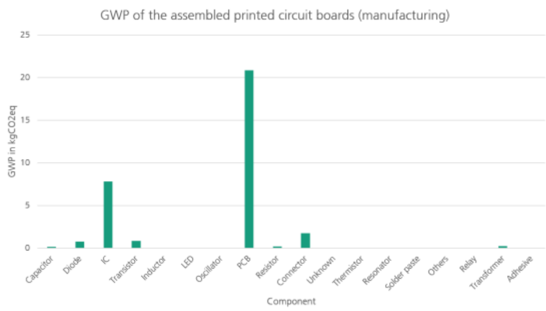

**Figure 2. GWP of the oven's assembled PCBs.**

If we now calculate the rest of the oven very roughly using material weights, the GWP should be around 100 $kgCO_2eq$ (without transportation) for this model. This leads to two statements. First, replacing the printed circuit boards in case of a malfunction or failure is highly recommended in order to its share of nearly one third of the total GWP. Second, the yearly carbon footprint of the PCBs is relatively low with an assumed lifetime of 10 to 20 years in particular. Thus, repairing the boards by exchanging single components could produce a higher ecological impact than changing the whole PCB because of logistics, use of tools or necessary special working environments. This product-specific circumstances needs to be investigated more closely.

The use phase of electronic products is characterised by their electricity consumption (idle, standby, low active, high active) and thus pending on the local electricity mix. In consideration of any energy efficiency improving potential, the following question arises: Is it worth changing components or even entire products early because of energy efficiency? With an estimated yearly electricity consumption of 140 kW and the current German energy mix (400 $gCO_2$/kWh), 15% of the ovens GWP proceeds from manufacturing and 85% from the use phase (assuming a lifetime of 10 years). The first consideration indicates the aspiration for a more efficient power supply unit in short and medium term as reasonable. However, if we assume a solar-wind-mix for the energy source (25 $gCO_2$/kWh), the manufacturing contributes 73% of the carbon emissions and only 27% the actual use. As the sustainability aspirations of the power grids accelerate, efforts to improve a more sustainable manufacturing phase (circular economy) is a meaningful approach.

For this kind of balancing various measures, an environmental cost-benefit analysis (Druschke et al., 2021) for the circular design options is mandatory. We identified some of the possible trade-offs: Robustness/reliability vs. reparability (oversizing), online condition monitoring (remote diagnosis) vs. maintenance/repair cycles (additional technical effort vs. mechanic trips) and Energy savings in the use phase (old vs. new product, energy costs and raw material costs).

In addition to the simplified LCA results, we have to evaluate failure statistics of the product and the technical concept for remote diagnostics, if available. The field of tension lies in the decision between integrating and adding sensors, a local or cloud-based data processing/evaluation, the used communication interface and IT security requirements. After clarifying these specifications, the scenarios for maintenance and repair cycles incl. kilometres driven, the creation of a life cycle inventory model for the comparative cost-benefit analysis is complete and flexible enough for changing or adding factors, suitable for a variety of specific electronic products. Note, that the sustainability of the supply chain is also important to consider as raw material criticality (geological, geographical, political, technical availability) is subject to a constant update by local ministries and scientific institutions. Furthermore, the potential use of recyclates by checking technical-economic requirements, availability, and certificates of origin to improve the overall ecological performance should be a crucial part in trade-off considerations as well.

In summary, this Bottom-up approach characterize a more simplified environmental assessment and create an orientated life cycle assessment, depending on the existing business requirements and specific contractual obligations. With this knowledge base, companies are able to weight up different options for action (for different timeframes and company divisions) and check their current policies for circularity readiness.

## Development of circular guiding principles and strategic measures

There are certain guidelines and principles in the literature towards implementing circular economy into business models and classifying required changes. The so-called R-principles are generic principles for developing circular products: Refuse, Rethink, Reduce, Re-use, Repair, Refurbish, Remanufacture, Repurpose, Recycle and Recover (Potting et al., 2017). They are the foundation to evaluate the current product design in consideration of a company's characteristics with to implement circular economy.

The process model for the identification of suitable R-principles consists of 1) Identification of criteria and characteristics for circular product design, 2) evaluation of the current product design using the characteristics, and 3) identification of suitable principles and recommendations (Scholtysik et al., 2022). Within this process, the authors identified 20 criteria, assigning to the areas of product design, business models and value creation, identifying synergies between current and circular product design (Figure 3).

| No. | Criterion | Area | | | Definition | Source (excerpt) |
|---|---|---|---|---|---|---|
| | | PD | BM | VC | | |
| 1 | Repair and maintenance information | | | x | Repair and maintenance information describes a defined sequence of processes to reinstate the functionality of the product | Morseletto, 2020; Bakker et al., 2014 |
| 2 | Quality inspection | x | | x | Quality inspection describes the way in which the functionality of a product is verified | Hollander et al., 2017 |
| 3 | Modularity | x | | | Modularity is a design option that divides the product into functional modules | Kalmykova et al., 2018; Morseletto, 2020 |
| 4 | Customization | x | | | Customization is a design paradigm that focuses on the individual customer's wishes in the product development process | Kalmykova et al., 2018 |
| 5 | PSS | x | x | x | A product service system is a marketable bundle of a product and a service | Acerbi et al., 2020; Alcayaga et al, 2019; Antikainen et al. 2018 |
| 6 | Partnership | | | x | In a partnership, a company enters into a cooperation with another company | Bigliardi et al., 2021; Bjørnbet et al., 2021; Lewandowski, 2016 |
| 7 | Platforms | | x | x | A platform is a marketplace for product enquiries and offers in a digital ecosystem | Acerbi et al. 2020; Chauhan et al., 2022; Heyes et al. 2018 |
| 8 | Customer acceptance | x | x | | The degree of willingness to embrace new functionalities describes the customer acceptance | Bigliardi et al., 2021; Bjørnbet et al., 2021 |
| 9 | Business relationship | | x | | The business relationship describes the customer segment in which the company is generally operating | Lüdeke-Freund et al., 2019 |
| 10 | Reverse Logistic | | | x | Reverse logistics involves the logistical processes in which products moves back from customer to the company | Bressanelli et al. 2019; Geissdörfer et al. 2018; |
| 11 | Operating Model | | x | | The operator model describes the underlying logic of the ownership of the product | Kalmykova et al., 2018; Morseletto, 2020 |
| 12 | Customer incentives | | x | x | Customer incentives refer to methods of rewarding the recovery of products and materials | Kalmykova et al., 2018; Lewandowski, 2016 |
| 13 | Sales markets | | x | x | The sales market describes the geographical focus in which the company operates | Acatech, 2021 |
| 14 | Spare parts availability | | x | x | Spare parts availability describes how long the company keeps spare parts in reserve | Morseletto, 2020 |
| 15 | Material diversity | x | | | Material diversity describes the variety of materials used in the product | Cayzer et al., 2017 |
| 16 | Longevity | x | | | The design of products for an extended product life cycle is called longevity | Morseletto, 2020; Bakker et al., 2014 |
| 17 | Accessibility | x | | | Accessibility describes how well critical components can be accessed for repair or exchange | Hollander et al., 2017 |
| 18 | Connections | x | | | The connections between components affect the interchangeability of the individual components | Ellen MacArthur Foundation, 2013; 2015 |
| 19 | Upgradeability | x | x | | Upgradeability describes the opportunity of integrating new functions into an existing product | Sihvonen et al., 2015; Bakker et al., 2014 |
| 20 | Data | | x | x | Data, that is generated during the product life cycle | Shennib et al., 2021 |

**Figure 3. Criteria for implementing circular economy. © (Scholtysik et al., 2022).**

Characterizing each criterion and scoring every characteristic in relation to the R-principles of a specific company creates an evaluation matrix, showing for synergies between current product designs to the R-principles. Each characteristic is evaluated according to whether it had a negative, neutral or positive influence. The aim is to classify the product in terms of circular suitability and show the need for action, prioritize measures and derive initial recommendations. This Top-down approach, creating standard strategies by rating the R-principle alignment of the product is a valuable complement to the orientated life cycle assessment, to support the circular mission statement development.

## Conclusions

The Methodology presented combines the process for creating circular guiding principles on a strategic level with the ecological cost-benefit analysis of potential scenarios and concrete measures based on the 5C Method. Whether starting with the norm strategies and calculating the carbon emission saving potential of derived measures from the R-principles or calculating the environmental footprint and assess trade-offs and derive strategic measures from there, ether way is a reasonable approach. Helping companies by providing these kind of procedures and accompanied processes, is mandatory for the necessary switch from linear to circular economy.

# The BIO TEN Design Guidelines: Inspiring biobased, local, durable and circular innovation in fashion textiles

**Rebecca Earley, Laetitia Forst**
University of the Arts London, United Kingdom

**Keywords**: Circular Design; Bio-Based Materials; Professional Training; Small Fashion Businesses; European Regions.

**Abstract**: Using design to change the way we make, use and reuse resources, materials, products, and services, has been widely recognised as an important element in creating a lower-impact clothing industry. A broad range of designers and sectors are involved in the various processes of decision-making that producing textiles and clothing entails. The research presented in this paper is concerned with how we might train professional designers working in SME's – small to medium scale enterprises - across Europe to make durable, long-life clothing that will be appropriate and fit for use within the emerging circular bioeconomy. This paper presents work developed as part of the design work package of the HEREWEAR project. The project is an EU H2020 FNR funded initiative (Food and Natural Resources), bringing together 15 different partners from 13 countries to explore systemic innovation for circular, biobased, local textiles and fashion. The HEREWEAR consortium is developing new fibres from agricultural waste -agriwaste - and pioneering (digitised) production, use and business models for local contexts. The design researchers in the project are tasked with the development of guidelines for biobased, circular, and local fashion textile design. This paper introduces the guidelines and discusses their value as a tool for professional training of design stakeholders, in the transition to a sustainable and circular fashion industry.

## Introduction

This paper presents research concerned with a training framework for designers in small to medium sized clothing companies in Europe, with a focus on regional contexts and values, as well as using bio-based materials, made from agriwaste streams, in ways that make the new clothing durable and long-lasting, as well as recyclable at end of life. The training framework builds on previous training offers, which have been widely tested in industry and academia, (Earley *et al,* 2016) but in this project more specific conditions have been applied – local, circular, and bio-based.

## Context

In the context of a climate emergency, design work must be aimed at shifting the current situation towards a decarbonised, sustainable, and circular state. The IPCC warns that the timeframe for change is short, and that drastic action must take place across sectors (Intergovernmental Panel on Climate Change, 2022). The fashion industry, notorious for its heavy impact on the environment and its ill-treatment of workers across the globe is coming to terms with the scale and ambition of the changes needed (Amed *et al.*, 2022). Many initiatives are currently under way to address the various angles of the crisis, from slowing consumption (Coscieme *et al.*, 2022), to driving a shift to circularity (Duhoux *et al.*, 2022; McKinsey, 2022), to creating roadmaps for net zero (Earley 2021). This research positions itself within this context and offers a complementary perspective by aligning topics such as circularity and decarbonisation in a way that can be relevant to design stakeholders in professional learning contexts.

## The HEREWEAR project (HW)

The HEREWEAR project aims to contribute insights and practical recommendations for the use of novel biobased fibres in local and circular contexts. The project partners are developing new fibres from agricultural waste and experimenting with PLA from sugar cane as alternatives to the ubiquitous use of cotton and polyester. This offers opportunities to move away from the fragile global supply chains meshed with these resources. To support this shift, attention is brought to the potential of local networks for manufacturing and use and reuse of garments, exploring new business models and the potential of the micro-factory concept. Circularity is a pathway to improved sustainability, and whilst garments are designed for long lives and multiple repair and reuse cycles, they are also considered as resources for future products and designed as such. To support designers with navigating these aspects of a transition to a sustainable fashion industry, a set of guidelines have been created and are presented in this paper. The work presented here stems from this recognised need to continue educating professionals for a transition to a decarbonised and sustainable fashion industry and explores the challenges of providing adequate information and formats for this audience. Lifelong learning is argued as a key part of professional life, in particular in an ever complexifying world (Laal and Salamati, 2012). The boundaries between where knowledge is acquired (education) and where it is applied (work) are blurred (Fischer, 2000). The tools for lifelong learning are many, breaking beyond adult education to include self-directed learning and collaborative practices. Knowledge exchange (KE) has been articulated as the bridge from fundamental research to applied contexts in industry and professional practices (Yusuf, 2008).

The many approaches to knowledge exchange which contribute to the application of emerging research to applied contexts and to gain new insights from these contexts are drawn from to produce a resource that is useful to design stakeholders in facing the challenges of a transition to biobased, circular, and local fashion systems. It is acknowledged that knowledge is not a fixed thing (Fazey *et al.*, 2013), and that in the process of exchanging with design stakeholders to produce the outcomes presented here, iterative versions of the guidelines were shaped in conversation between the research team and design stakeholders.

## Methods

The aim of the work described here is to inspire fashion brands to explore biobased, local, durable, and circular innovation. The team developed a framework and a set of guidelines to achieve this aim. The method used was to adapt a set of existing guidelines (The TEN[1]) developed and tested in previous projects to the specific context of the HEREWEAR project. The new guidelines (The BIO TEN) were developed via a literature review of existing industry design and production recommendations and supported with a review of key case studies from contemporary design practice. The draft set of guidelines were then used in a series of four workshops with project partners and with small fashion brands and industry representatives in Romania and in Belgium.

The design decisions that related to the developing guidelines were reviewed and mapped against the material lifecycle of a biobased fashion textile[2] in online workshops hosted in Miro in the first workshop with project partners. Then the guidelines were taken to design students at the University of the Arts London and to groups of fashion SMEs and industry stakeholders in Iasi and Antwerp, to test the use of the guidelines in the design process and review the garment concepts that were collaboratively created using the BIO TEN as inspiration. All workshops were designed and facilitated by the authors and colleagues (based at Centre for Circular Design, UAL).

| Dates & Locations | Participants |
|---|---|
| June 2021, Dec. 2021, online, in Miro | 10 people: SME project partners: Vretena, Mitwill; Technical expert HW project partners: DITF, Rise, Circular.Fashion |
| Jan. 2022, London, UK | 30 people: Graduate diploma students in textile and graphic design courses |
| May 2022, Iasi, Romania | 20 people: Local fashion SMEs, community design HW project partner: Maibine |
| June 2022, Antwerp, Belgium | 15 people: Local fashion industry stakeholders (policy makers, brands); Technical expert HW project partners: DITF, Centexbel |

**Table 1. List of workshops and participants.**

*[1] The TEN were co-developed between 1996-2009, at Chelsea College of Arts, London – first published as a card deck in 2010; then used with multiple fashion and textile and other companies, resulting in different versions being released over the years, along with animations and how-to films and workshop tools, www.circulardesign.org.uk/research/ten/*

*[2] The material lifecycle map is a tool to describe the different stages of the production and use of a biobased material https://herewear.eu/category/material-portrait/*

Using the input from the workshops, the wording and formats to communicate the guidelines were adapted to produce the guideline tools presented here.

## The BIO TEN Guidelines

The TEN design for sustainability tool - a widely tested resource identified as one of the most effective for use by fashion designers (Kozlowski, Bardecki and Searcy, 2019) - has been used as the basis for these guidelines. We have taken our insights and findings from developing and working with The TEN over the last 12+ years, revised and updated them, drawing from our circular design work from recent research and industry projects (Turbito *et al* 2018; Earley & Goldsworthy 2019;), along with circular economy and circular design guidelines from other organisations. The result is a reframing of designing for bio-based textiles, keeping the broader, systemic transformative potential of The TEN, whilst also locating the specific questions that will enable appropriate decision-making with the HEREWEAR materials, products, partners, and broader communities.

The first set of strategies encompass selecting bio-based materials according to end of-life trajectories; production and waste reduction decisions, and textile selection – these are the elements that are essential to the guidelines as they are enacted by design stakeholders working at all scales. The second set of strategies ask the design stakeholders to ensure that the bio-based materials and products they are designing are as durable and long-lasting as possible. The third set of strategies are about the role design stakeholders must play in communicating the key messages around bio-based materials and products, so that users and others are involved in appropriate and effective ways in the bio-based circular models.

The flow represents a journey through the design decision making in order, starting with what you need to start with in circular design – the end of-life trajectory. The guidelines thus follow a full lifecycle approach, essential to circular design, but also offer a holistic perspective on the actions necessary for circularity by including communications and marketing for behaviour change.

Design for Circular, Local, and Less

The initial design process anticipates the potential for eventual recycling and re-purposing of the bio-based textile product. Designing with the end in mind steers our biobased material, product or service down a particular reprocessing or regeneration route. It encompasses selecting bio-based materials according to end-of-life trajectories and lowest possible impacts; production and waste reduction decisions – these are the elements that are most key to the guidelines as they are enacted by design stakeholders working at all scales, and it is here that the biggest impacts occur.

1. **Design for Recycling:** End-of-Life Trajectories & Cyclability; Donating, Collecting, Sorting
2. **Design for Production:** Local, Ethical & Sustainable Manufacturing
3. **Design to Minimise Impact:** Selecting, Finishing & Embellishing
4. **Design to Minimise Waste:** Zero Waste Patterns, Factory Waste & Fallout

### *Design for Circular Lifecycle Extension*

Understanding more about the things we make, why and how people use them, stop using them, and how they get rid of them, is key to creating circular bioeconomies. It's important that we make bio-based products last for as long as possible. These strategies are about designing a bio-based material or product in such a way that the user can get maximum use and value from it during the period of their ownership, extending its life and therefore eliminating the associated impacts that comes with buying something new. It considers repair and upcycling which can keep the material in circulation for longer without having to break it down into a new feedstock.

5. **Design for Durability:** Physical, Aesthetic & Emotional Durability; Washability & Wearability; Repairability
6. **Design for Change:** Customisation, Multifunction, Adaptability & Modularity
7. **Design for Sharing:** Rentability, 'Swappability' & Returnability
8. **Design for Upcycling:** Remaking & Remanufacturing

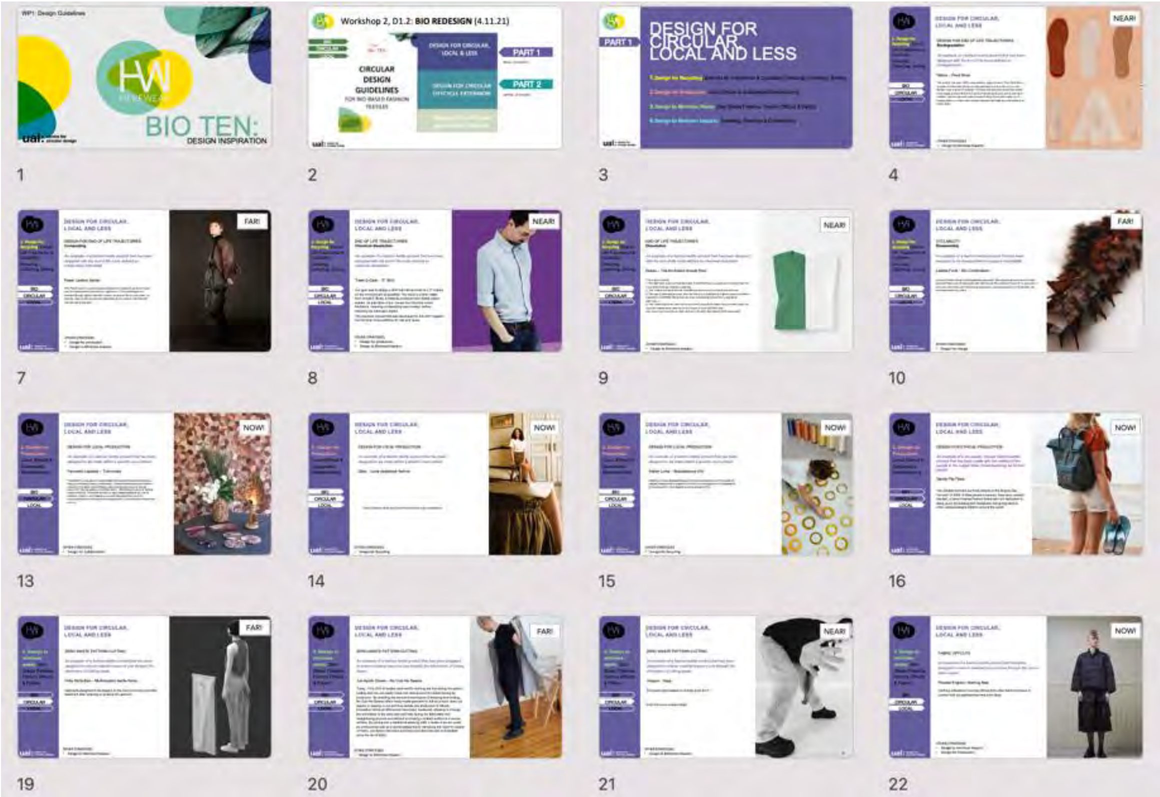

Figure 1. The BIO TEN design guidelines exemplars as a slide deck for presentation by an expert.

Figure 2. A BIO TEN exemplar slide with information relating to the innovation and coded against the biobased, circular, local approaches and the now, near, far placement.

**Figure 3. An example of a design challenge card (left, the front, and right, the back of the printed card used in workshops).**

*Design for Circular Behaviour Change*

Design can be used to create messages to drive behaviour change. These strategies are about the role design stakeholders must play in communicating the key messages around the bio-based materials and products, so that users and others are involved in appropriate and effective ways in the bio-based circular models.

9. **Design for Communication:** Reducing, Respecting, Labelling, Marketing & Activism
10. **Design for Collaboration:** Materials, Models, Mindsets & Methods

## The BIO TEN in action

The guidelines' success is measured in relation to their ability to support the design process and lead to the creation of products and services which replace environmentally damaging practices with more benign ones (Forst et al., 2023). The BIO TEN were developed into communicable formats for knowledge exchange with designers and to support ongoing learning on the topic of sustainable and circular design as part of their professional practice. To illustrate each guideline in design applications, a series of exemplars were gathered (Figure 1). The guideline is put forward as a recommendation to design stakeholders alongside an example of how this might be affected. They offer a provocation to the learners and an example of how they might take on such an angle. The exemplars have been used both as slide presentations delivered by a researcher 'expert' to a team of design stakeholders, or as cards for professionals to explore independently (Figure 2).

A layer of analysis is included in the exemplar representations: It is acknowledged that very few businesses currently encompass all three of the HEREWEAR pillars, thus, each case study is marked to account for which of the pillars were addressed and which were left out. Similarly, the cases were marked as 'now, near, or far' to account for the fact that not all products and projects are at the same level of development, or occupy the same place in the market, in particular in the field of biobased materials (Lee *et al.*, 2020).

To build on the knowledge and inspiration acquired through the discovery of the guidelines through the exemplars, a complementary workshop tool for the adoption of the BIO TEN was developed – The Design Challenge Cards. (Figure 3) These cards convert the exemplars into questions for how designers might produce their own response to the guideline which uses all three of the HEREWEAR pillars. The questions are left open to prompt designers to imagine new products or services, while drawing inspiration from the case study provided. The design cards and the exemplars can be used together, starting with a presentation of all guidelines, and then moving to a design activity with the challenge cards, or separately. The aim is to support the exchange of knowledge from the research into the fashion industry, and gain insights from applied contexts.

The guidelines were used in workshops carried out with postgraduate design students and small brands. These events aimed to gather the community in specific local areas to discuss the challenges they encountered in relation to the HEREWEAR agenda in their work. To structure the discussion, the participants were asked to use the guidelines in a rapid redesign exercise, where they would reimagine an existing product, either from their own range or a classic piece, and weave in the recommendations to make it biobased, circular, and local. It was found that designers could easily integrate some of the lessons from the guidelines using the exemplars and that the lessons learned from the new garment concepts were useful to iterate and refine the tools. The variety of cases provided an open approach to the guidelines, rather than restricting the process they act as an inspiration.

The opportunity for design professionals in fashion brands to encounter the result of recent research can lead to the integration of circular and sustainable strategies. To make the recommendations from research inspiring, the tools to communicate them must be in line with their existing processes and speak their language. This project shows how in an iterative process with small brands, the research team developed variations to translate the new BIO TEN design guidelines.

Insights for biobased, local, circular fashion

Developing and applying the BIO TEN guidelines in garment concept development workshops with brands highlighted some of the challenges and opportunities for circular design with biobased materials, in local systems. It is widely accepted that these are three pillars of design for sustainability that can contribute to a needed change (Ellen MacArthur Foundation, 2017; Changing Markets Foundation, 2020; Textile Exchange, 2022). However, confusion and lack of accessible information remains an issue in professional contexts. It was found that widely used circularity guidelines needed to be amended to account for the challenge of working with novel biobased materials. It also became apparent that more detail could be added to the current recommendations on durability and repair to account for local contexts for manufacture, use and reuse. Bringing all three pillars together in a garment concept also pushes designers to think more holistically about resources, manufacturing, use and end of life, thus leaning into design for behaviour change for industry stakeholders and users. The BIO TEN guidelines offer the opportunity for designers to combine all key aspects of a sustainable fashion system in their decision making, supporting ongoing learning with tools for inspiration in the early phases of the design process.

## Conclusion

To support ongoing learning in professional environments which will be increasingly shaped by the climate emergency, a range of tools must be available to designers, including resources to act as inspiration at the start of a project. As demonstrated here, open recommendations which offer an overview of the holistic approach to circularity which is necessary to operate a full industry shift can be used with design teams. There is also a need for technical tools that can give concrete and product related instructions, these are explored in the next phases of the HEREWEAR project. The project partners are continuing draw insights from knowledge exchange with fashion professionals and to explore how best to support designers including using qualitative insights from life cycle assessments (LCA) and developing a digital tool for product design development integrating biobased, circular, and local innovation approaches.

# Seeing Complexity in the Circular Economy: A Product Packaging Case Study

**Nathan Eng, Marco Aurisicchio[(a)]**
a) Imperial College London, London, UK

**Keywords**: Cynefin; Sense-making; Packaging; Circular Economy; Complexity.

**Abstract**: The management of complex systems in The Circular Economy (CE) is made difficult by a myriad of unknowns. Non-linear issues like process interactions, infrastructure availability and human behaviour interfere with the design and optimisation that CE needs for technical and economic viability. Existing research focuses on quantifying or approximating those unknowns to improve understanding of complex processes with interactive models. This becomes impractical, however, as models are required to incorporate more and more realistic factors. This research proposes that these modelling approaches intrinsically limited by their failure to distinguish between types of unknowns. While analyses can help to understand information *that is not yet known*, true complexity is characterised by *fundamental unknowability*. This research proposes the combination of the Cynefin sense-making framework and a CE-focused system element classification to develop a practical understanding of the knowable-unknowable distinction. An illustrative case presents application to two related but contrasting packaging: mature and optimised aluminium beverage cans and emerging polylactic acid (PLA) bioplastic bottles. Results show a mix of deterministic, complicated, complex and even chaotic sense-making contexts among product life cycle processes. Cynefin provides guidance for managing processes within each context as well as for dynamic transitions between them. It also provides possibilities for balancing the granularity of analysis. This concrete CE case demonstrates the relevance and benefits of a potentially abstract framework in action. Future work involves the application of this process to compiling diverse stakeholder perspectives and linking outputs to other CE methods.

## Introduction

The Circular Economy (CE) approach proposes waste elimination through the collaborative management of product life cycles. It seeks sustainability by designing systems to retain technical materials and regenerate biological systems (Ellen MacArthur Foundation, 2015). The coordination of decisions across material suppliers, product manufacturers, distributors, retailers, customers, collectors and recyclers requires new levels of collaboration and presents new kinds of uncertainty about issues like cost sharing, customer behaviours and emerging technologies.

The above issues are compounded by an emerging tendency in some CE literature to neglect critical differences between kinds of uncertainty: things that are *not yet known* versus those that are *fundamentally unknowable*.

This paper explores the application of the "Cynefin" sense-making framework (Kurtz & Snowden, 2003) to improve the management of unknowns in product packaging transition to CE. This is illustrated through a case contrasting the life cycles of aluminium cans and polylactic acid (PLA) bottles. By making better sense of unknowns in the case studied, this work seeks to demonstrate the value of Cynefin as a basis for stakeholder collaboration and integrated methods management.

## Literature

### *Approaching Complexity in CE*

The coordination of resource flows required by CE drives the creation of relationships across numerous boundaries and the definition of new Resource Flow Systems as illustrated in Figure 1 (Zeeuw van der Laan & Aurisicchio, 2021). This wide-reaching integration across multiple scales is widely-regarded as complex due to unknowns at almost every stage and level such as:

- Consideration of diverse and incommensurable value types across resource lifecycles (Millward-Hopkins et al., 2018);
- Unpredictable user behaviour (Jacobsen et al., 2022);

- Recovering diverse materials from intricate assemblies (Jacobs et al., 2022);

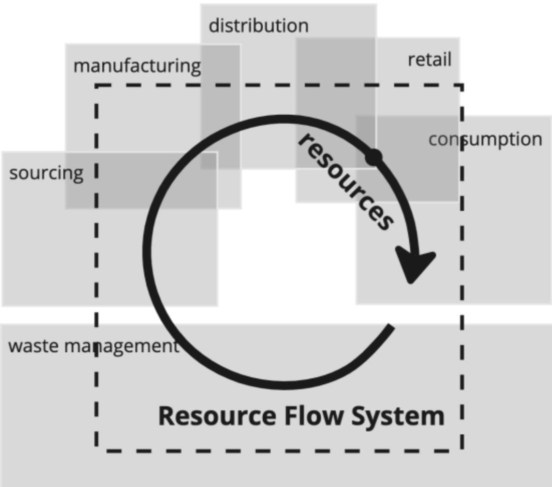

**Figure 1. Resource Flow System Concept.**

What is less clear is how to manage these unknowns. The trend is to model these systems for improved understanding, however, computing tools are limited by lack of data (Bassi et al., 2021). Worse, even when focusing on key features of CE like value management, there is an absence of models that can span “social, environmental, economic and technical domains" (Iacovidou et al., 2017). This *dynamic complexity* and *deep uncertainty* generally lacks methods and tools adequate for the necessary multidimensional analysis (Coenen et al., 2018).

This lack of successful methods and tools appears to be a symptom of an incomplete approach to managing complexity and uncertainty.

### *Making Sense of Order: The Cynefin Framework*

Cynefin is a framework for identifying and visualising the nature of uncertainty in systems and selecting corresponding management approaches (Kurtz & Snowden, 2003). Cynefin's fundamental conceptual insight is that effective management remains possible even in the context of irreducible unknowns. This is achieved through rigorous "sense-making" processes. **Domains** are defined by the effect of system structure on knowability and they contain distinct *sense-making contexts*:

- **ordered domain:** knowable, divided into *deterministic* (completely, mechanistically definable) and *complicated* (understandable with expertise);
- **unordered domain:** not fully knowable but manageable through interaction, split between *complex* (elements co-evolving with unpredictable emergent patterns) or *chaotic* (weakly-bound elements, unknowable whole); and
- between them lies the **disordered domain** where different perspectives disagree on knowability.

The Cynefin concept space is visualised in Figure 2. The typical "square" is rotated onto a corner to avoid implications of a 2x2 table. Boundaries (grey lines) are left off until later sense-making steps to focus attention on relative comparison between elements and the four context "corners". There is no preferred quadrant and forced categorization should be avoided. If a process does not fit one context, it should be left on a boundary or split up. This defines processes that can be managed by related strategies without ignoring nuances.

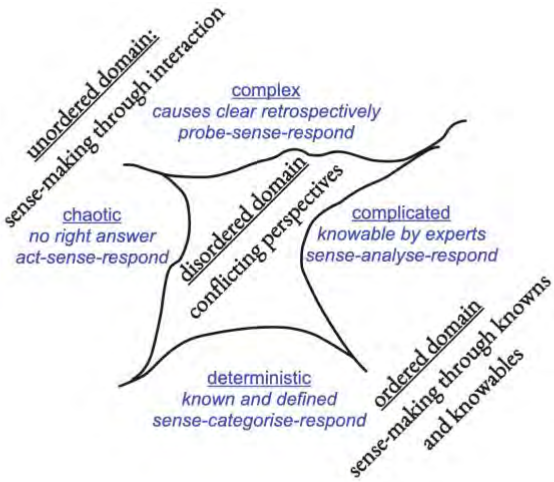

**Figure 2. Cynefin’s Three Domains and Four Sense-making Contexts.**

Beyond the management implications within contexts, Cynefin also describes “dynamics” that result from (natural or managed) migration between contexts as a result of imposing or relaxing constraints like physical control or formalised relationships.

### *Challenging the Complexity of the Circular Economy*

Cynefin provides a model *of* complexity to better guide action *within* complex systems. It prioritises emergent, interactive management approaches where a situation is characterised by unknowability while validating the use of deterministic modelling and analysis in the ordered domain.

The diversity of systems within CE presents numerous intersections where those distinctions are critically relevant. For example, Life Cycle Analysis (LCA) tends to leave out critical feedback loops at the interface with social systems (Nika et al., 2020).

The inability of analytical models to manage unknowable contexts is indicated by difficulties managing real-world complexity with models alone. In their comprehensive review of Closed-Loop Supply Chains (CLSC) Coenen et al. conclude that effective methods and tools for dealing with uncertainties beyond probabilistic and fuzzy models (e.g. technological disruptions or unpredictable actors) are "completely missing from the CLSC management literature" (Coenen et al., 2018). When extending models for complex value assessment, researchers note the necessity of grounding those analyses in narratives that help understand broader systemic changes (Millward-Hopkins et al., 2018).

Sensing patterns in complex contexts requires the combination of diverse perspectives (Kurtz & Snowden, 2003) and participative methods are studied for this in CE work. Research on the Consumer Intervention Mapping (CIM) demonstrates its value by supporting nuanced Product Service Systems discussions (Sinclair et al., 2018). Prompting tools like the Circularity Deck facilitate innovation discussions (Konietzko et al., 2020). Similarly, visual tools like Flow Mapper (Zeeuw van der Laan & Aurisicchio, 2021) and Causal Loop Diagrams (CLD) (Roodt & Dempers, 2020) are applied to focus productive stakeholder collaborations. Some of these methods, like CLD, include guidance on evolving into analytical models but many do not.

Despite some awareness of Cynefin's potential (Bozesan, 2023; Naim & Gosling, 2023) and application in adjacent areas like resilient infrastructure (Helmrich & Chester, 2022), practical applications of the framework in CE product transitions is lacking. The following sections demonstrate the specifics of Cynefin sense-making applied to a CE packaging context, showing how to effectively combine contributions from each of the above research areas.

## Methodology

The Cynefin framework was applied to an exploratory case to contextualise major life cycle processes in successful (aluminium beverage cans) and emerging (PLA bottles) product packaging. These packaging examples were selected for a balance between similarities and contrasts to illustrate how the framework applies to a range CE situations.

In a real design situation, product information would be elicited from a combination of research and stakeholders perspectives. The goal here is not to provide authoritative technical information but to illustrate a CE sense-making case with reasonable details. The case uses three major steps to apply sense-making and CE frameworks.

### *Step 1: Background Product Life Cycle Research and Life Cycle Overview*

Literature research is used to develop a high-level process diagram for the two product packaging, identify the system elements affecting each process and provide narratives of each phase to ground sense-making details.

One of the most critical tasks in trying to understand systems is determining the model granularity. The scope must be a balance between:

- Oversimplifying down to too few processes and elements, hiding key insights; and
- Overloading sense-makers with too many processes and elements, slowing work and creating confusion.

In the packaging examples studied, a complete but high-level life cycle is developed to limit initial granularity.

### *Step 2: Table-based Coding and Tuning Granularity*

First, each packaging is analysed for each process using the CE-focused system element classification (Zeeuw van der Laan & Aurisicchio, 2021). Elements elicited in this way are then coded for a sense-making context by considering the question? "*How could we know the impact of this on the process results?*". Answers may be:

- Deterministic: The result could be calculated or predicted by anyone (light grey).
- Complicated: An expert would know (dark grey).
- Complex: The result only makes sense in retrospect (green).
- Chaotic: The result is too random to determine a right answer (red).

Second, the system elements influencing a process are examined for dominant sense-making contexts. All elements of a process rarely conform to a single context. Identifying unexpected nuances and avoiding forced categorization is central to the sense-making power of Cynefin. Assessing the most impactful unknowns is a collaborative activity that may result in having to situate a process at a context boundary or even within the disordered domain. Further progress out of disorder requires increasing granularity (adding rows) to separately consider elements and processes in more detail.

In this way, the process scope being considered is set by the knowability of internal factors instead of some default decomposition that neglects key details.

### *Step 3: Cynefin Visualisation and Identification of Management Strategies*

Once a round of coding is completed, the processes and system elements can be visualised in the Cynefin sense-making space. Beginning with just the four "corner" titles as anchors, processes and elements are placed relative to each other. These points form the basis for drawing the overall sense-making domain boundaries in between, and sometimes *through,* the visualised processes. Stakeholders can then evaluate appropriate management strategies based on locations within and across contexts.

| System Element | Definition | Example Elements Affecting Aluminium Cans | Example Elements Affecting Bioplastic Bottles |
|---|---|---|---|
| Principle | Rules and circumstances that do not easily change (laws, standards, agreements) | Existing and Emerging EU laws (European Commission, 2022) | Emerging EU laws (European Commission, 2022), compostability standards |
| Value | Activities that deliver business value (services, transactions) | Cost of virgin and recycled of aluminium, infinitely recyclable base metal | Cost of virgin and recycled PLA, biodegradable and plant derived plastic |
| Actor | Actions and behaviours of and between stakeholders on resources (motivation, interaction) | Consumer habits and knowledge about aluminium | Consumer habits and knowledge about PLA (Taufik et al., 2020), Manufacturers (Eco For Life, 2023) |
| Data | Information gathered and provided (data on resource, user interaction) | Alloy data, throughput data, disposal labels, industry performance reports (The Aluminum Association, 2021) | Bioplastics data, chemical characteristics (Ghomi et al., 2021), decomposition performance |
| Infra-structure | Facilities, equipment and consumables (production means, energy) | Foundries, manufacturing factories, transportation, recycling plants | Crop fields, manufacturing factories, industrial composting plants |
| Resource | Resource (material, component or product) qualities (appearance, physical property) | Aluminium melting point, appearance, cycle-ability of can alloys (Niero & Olsen, 2016) | PLA compostability, PLA appearance |

**Table 1. Flow Mapper System Element Classification and Related Examples of System Elements.**

## Results

### 1) Product Life cycle Background

Aluminium beverage cans are an established, highly-optimised packaging with both general recycling and deposit-based recovery streams motivated by the high intrinsic value and recyclability of aluminium.

In contrast, PLA bottles are an emerging packaging using a material that has the potential to mitigate the environmental impacts of fossil fuel alternatives if managed properly (Ghomi et al., 2021).

Both beverage containers must endure a range of supply chain conditions, and are typically used away from the home and discarded soon after use.

Elements influencing the flow of the two containers are presented in Table 1 and a high-level synthesis of the life cycle is presented in Figure 3.

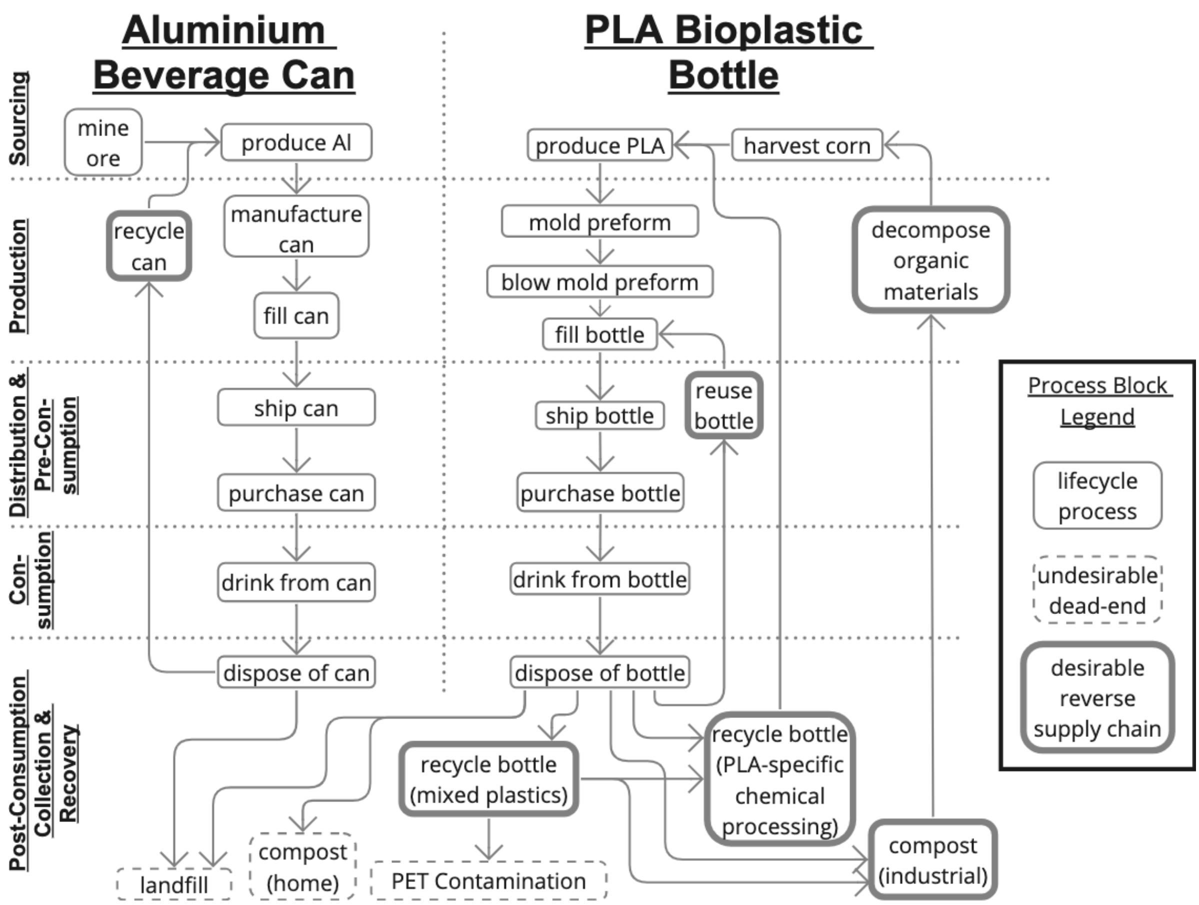

**Figure 3. Product Packaging Life Cycle Process Comparison.**

### 2) Tabular Coding and Tuning Granularity

The coding table was created with rows for each of the major life cycle processes in Figure 3. Within a row, each product package is analysed using the system element classification and then coded according to sense-making contexts. While a full discussion of each result is beyond the scope of this paper, an overview shown in Figure 3 and details of an example row are presented in Table 2.

Early life cycle processes (sourcing, production, distribution and pre-consumption in Figure 4) tend to be similar and focused on deterministic and complicated contexts for both packages. Uncertainty that can not be constrained out of industrial processes (light grey) is dealt with by experts in factories or the supply chain (dark grey).

Complexity (green) tends to arise when dealing with new processes, novel legislation or consumer behaviour. In the "distribution and pre-consumption" process, for example, it is hard to anticipate what price premium consumers will tolerate for sustainable features because of trends, social factors and preferences even if they can articulate reasoning after a purchase.

**Figure 4. Overview of Results Table to Illustrate Colour Coding.**

Chaos was mostly observed around novel processes where consistent outcomes have not yet stabilised. The "disposal" process, for PLA involves a haphazard mix of emerging regulations, variably-deployed infrastructure, novel consumer behaviours and inconsistent information. For example, there is conflicting information about the compostability of PLA. Some sources indicate that it might take a century to decay in the environment (Ghomi et al., 2021) while product marketing information may not emphasise the need for industrial composting (Eco For Life, 2023). New regulations limit ambiguous labelling but their relevance will depend on which bioplastics succeed.

Finally, in contrast to emerging PLA composting, "aluminium can disposal" was seen as too disordered to fit a single context. In the USA, although 92.6% of recycled aluminium is reused, consumer recycling rates have averaged around 50% *for 20 years* (The Aluminum Association, 2021). The maturity and efficiency of the ordered elements are being disrupted by unpredictable consumer behaviour. Figure 5 shows how it might be split up to better consider elements in later rounds of sense-making.

### *3) Cynefin Visualisation and Managing Dynamics of Context Transitions*

The Cynefin visual in Figure 5 maps the processes from Table 2 and illustrates a number of multi-context dynamics.

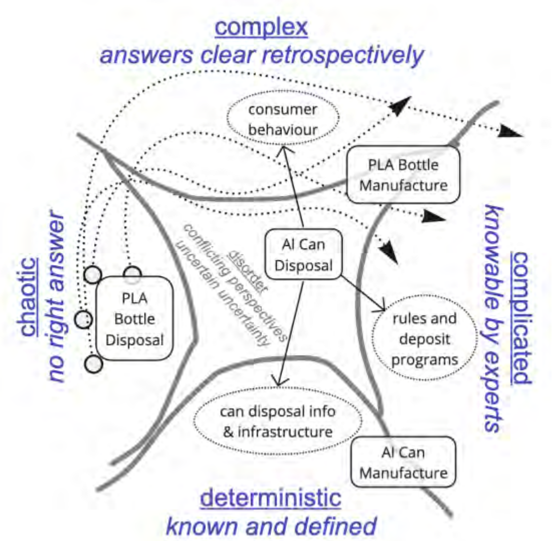

**Figure 4. Cynefin Visualisation of Selected Processes.**

The *deterministic-complicated* boundary exchange is typical of incremental technical development like highly-optimised aluminium can manufacture and recycling.

*Complex-complicated* iterations are typical of cutting-edge technical development like the innovation in PLA bottle manufacture and recycling. Processes develop new knowledge (visit complex space) and formalise key findings to disseminate and build efficient routines (move to complicated space). New legislation might also follow as it emerges from dialogues between communities, governments and industry (Schmidt & Engelmann, 2023) to eventually stabilise into routines and infrastructure.

The *chaotic-complex-complicated* progression represents a path for chaotic processes like PLA bottle disposal. The Cynefin framework describes this as a “swarming” dynamic where a situation is seeded with “attractors” that encourage self-organisation and the emergence of a *complex* pattern (e.g. incentives). Desired stable patterns can then be formalised and scaled (e.g. via regulation and permanent infrastructure) which shifts the situation to *complicated*.

| Process | Aluminium Beverage Can | PLA Bioplastic Bottle |
|---|---|---|
| | | |
| Disposal | *Narrative: Consumer finishes beverage contents and looks to dispose of can.*<br><br>**Principles**: Established legislation on Al can waste.<br>**Value**: Al is perceived as a valuable material, has direct cash value with deposit program (increases consumer returns but also motivates scavenging activities).<br>**Actor**: Consumer has habit to recycle Al but may not have sufficient motivation in some contexts.<br>**Data**: The can has information on recycling; companies advertise on recycling; local authorities provide information on recycling to households.<br>**Infrastructure**: Recycling bins are widely available in the public; general waste bins are also available (not accepted); can deposit programs provide single-stream returns.<br>**Resource**: Al is known as a recyclable material.<br><br>**Disordered process due to mixed contexts including established mature infrastructure, complicating economic incentives and idiosyncrasies of consumer behaviour that limit progress towards circularity** | *Narrative: Consumer finishes water and looks to dispose of bottle.*<br><br>**Principles**: Emerging EU legislation on PLA packaging and its waste: shall be recyclable without affecting the recyclability of other waste streams (European Commission, 2022).<br>**Value**: Some residual value if recycling available; divert waste from landfill as it can be composted or incinerated.<br>**Actor**: Consumer may apply habits from similar products (i.e. PET bottles), not read the packaging label, lack knowledge of PLA packaging and how to dispose of it, not be motivated to look for a food waste bin.<br>**Data**: Manufacturer marketing information: chemical free, sustainable, GM Free; manufacturer disposal guidance: compost, incineration, biodegrading.<br>**Infrastructure**: Industrial compost services are not publicly available and inconsistently deployed; plastic bin recycling may cause contamination of PET stream without infrared-based sorting; general waste bins.<br>**Resource**: PLA looks identical to other plastics like PHA and PET.<br><br>**Chaotic process due to inconsistent consumer behaviour, incomplete information and random state of infrastructure and incomplete understanding of novel material.** |

## Discussion

### *Moving from Differences in Scale to Differences in Kind*

In approaching the complexity of a CE transition, it makes sense to leverage successful approaches like LCA and scenario modelling. These are invaluable for verifying the economic and technical viability of new products. They excel at building an understanding of information that is *not yet known* though they cannot deal with true complexity characterised by fundamental *unknowability*.

Further, this shortcoming can neither be fully addressed through linked simulation models, probabilistic functions nor fuzzy logic because the management of complex unknowns *requires* interaction. It is fundamentally different in kind, not just in scale.

Literature does include interactive, participatory approaches that are supported by qualitative modelling. These are critical for the integration of diverse perspectives necessary for complexity management. These methods, however, tend to be limited to the front end of CE transition: envisioning new strategies, developing criteria or evaluating tentative solutions.

In essence, the components for a complete complexity management strategy are present but they are bounded by conventions and unaddressed limitations. This research represents progress towards a meta-framework for integrating stakeholder perspectives in complex CE transitions. It demonstrates a process for negotiating the interplay between unknowns and unknowables and questioning assumptions.

At its core, Cynefin is a phenomenological framework; one that focuses on how and why stakeholders understand situations for decision-making (Kurtz & Snowden, 2003). This is a relatively abstract framing compared to typical management methods made up of familiar inputs, categories and expected outputs. The concrete, CE-centric examples presented here clarify the framework's benefits and motivate broader investigation.

### *Limitations and Future Work*

This demonstration used retrospective information and did not involve industry experts. A more participatory follow-up study is needed to demonstrate validity, improve technical accuracy and test integrations with other CE methods.

## Conclusions

This work combined the Cynefin sense-making framework with a CE-focused system element classification to address a conceptual gap in CE in dealing with complex unknowns.

The comparison of established packaging technology (aluminium can) with an emerging one (PLA bottle) demonstrated how the Cynefin framework can provide insights on a range of CE processes.

Overall, it argues for the importance of identifying "unordered" processes so that they can be managed better through interaction instead of analytical modelling.

# Designers Shaping Strategies for Fashion Remanufacturing: Case Studies from Melbourne/Naarm*, Australia

**Julia English**[(a)], **Miriam Borcherdt**[(a)]
a) RMIT, Melbourne, Australia

**Keywords**: Redesigned fashion; Localised remanufacturing; Remanufacturing partnerships; Circular business strategies; Textile waste management.

**Abstract**: Remanufacturing offers one solution to the fashion industry's growing waste problem as a potentially scalable approach to redesign fashion products. It is ranked above other strategies, such as recycling, and can contribute to the reduction of virgin material use, water and energy while repurposing existing waste streams. Within fashion, remanufacturing and upcycling overlap in practice, as remanufacturing remains niche, and upcycling practices can produce multiple units. Research has so far focused on individual businesses producing remanufactured products, however, in the Australian context, there are multiple examples of partnerships for small-scale fashion remanufacturing. This paper reviews these practices through examining three case studies of existing partnership structures from Melbourne/Naarm* – a Sub-brand, an Initiative, and a Residency. Two partnerships were included in each case study to reveal commonalities and variations in the partnerships created through the respective structures. The paper used publicly available information from websites, social media and observations of remanufactured outcomes to identify the attributed roles across the remanufacturing processes. The case studies show that the partnerships are instigated by different actors, and the designers may be internally positioned within the structure or be brought in as external contributors. In both instances, the strategic positioning of designer shapes the remanufactured outcomes in various ways, while remaining aligned to the designer's aesthetic. This paper draws on the work of current PhD research projects and shows the emerging role for partnerships in facilitating diverse methods for brands to participate in remanufacturing.

## Background

Textile waste poses significant challenges for transitioning the fashion industry towards a circular model. In Australia 181 560 tonnes were landfilled for disposal from July 2018-June 2019 (Australian Bureau of Statistics, 2020), and 105 900 tonnes were exported to developing countries over the same period (Allan & Allan, 2022). Remanufacturing is making new products from reclaimed materials through scalable production processes (Wen-hui et al., 2011) and it offers benefits through improved material and energy use (Allwood et al., 2011). It also delays materials from being landfilled, exported or incinerated, and, when decentralised through local production, it supports the local economy and has reduced impacts from transportation (Bridgens et al., 2018; Pal, 2017; Paras & Curteza, 2018).

Melbourne has a history of independent fashion designers working collectively, sometimes with existing materials (English & Pomazan, 2010). These upcycling practices are longstanding in fashion, and the term upcycling sometimes encompasses remanufacturing (Paras & Curteza, 2018; Sung et al., 2020). However, some suggest that remanufacturing should be differentiated from upcycling as operating at scale and creating clothing from clothing (Dissanayake & Sinha, 2015; Pal et al., 2021; Sinha et al., 2016), although some upcycling practices also meet the requirements remanufacturing (Aguilar Johansson & Runstrand, 2020; Dares, 2021).

Remanufacturing for fashion products can be generalized as involving sourcing (including sorting and reverse logistics), design (research, design and sampling), production (pattern development, cutting and manufacturing), and retailing stages (Dares, 2021; Dissanayake & Sinha, 2015; Han et al., 2017; Pal et al., 2021). Designers play a key role in developing remanufacturing methods, which may range from minor value adding to complete dis/reassembly, which are applied in relation to the input material (Pal et al., 2021; Weber, 2019). Remanufacturing methods use various redesign techniques which may include overdyeing, felting, cutting and resewing, embellishment, printing and patching (Pal et al., 2021; Paras & Curteza, 2018; Weber, 2019). Designers also make decisions through the remanufacturing stages, including assessing the suitability of garments for various remanufacturing methods and determining material combinations, colours and groupings (Pal et al., 2021; Weber, 2019).

Remanufacturing practices for fashion have been argued as still becoming established, and scaling faces challenges due to resource availability, production barriers, and communication to customers (Sung et al., 2020). Collaborative partnerships to develop networks to support reuse and remanufacturing are vital (Paras et al., 2018; Sinha et al., 2016), however, literature on partnerships for clothing remanufacturing is scarce. In public, partners are often not acknowledged for the role they play in the supply chain, such as manufacturers or collection agencies (Aguilar Johansson & Runstrand, 2020; Dares, 2021; Sinha et al., 2016). Otherwise, when partners are publicly acknowledged as brand collaborators, the role they play in the remanufacturing process remains unspecified (Dares, 2021).

This paper responds to the gap in knowledge about partnerships facilitating remanufacturing and provides examples of practices from Melbourne/Naarm*.

## Methodology

There are multiple case studies of fashion remanufacturing practices, which draw on observations, interviews and published information to identify the processes involved (Dares, 2021; Pal et al., 2021; Sinha et al., 2016). This paper reviews existing practices occurring in Melbourne to examine the various roles partners undertake. The parameters were that a remanufactured product was being sold, and that multiple brands or businesses were publicly attributed as contributing to achieving this outcome.

As a result of looking at 19 examples of remanufacturing and upcycling partnerships occurring between 2019-2021, the authors identified 4 types of structures, these were a Sub-brand, an Initiative, a Residency and an annual Campaign. As the Campaign only overdyed products from the general public, this paper looks at the first three structures, specifically through the lens of remanufacturing between businesses. Two partnerships conducted under each structure were included in the case study to identify similarities and differences in the roles undertaken and the outcomes produced.

This review of practices uses publicly available data to inform the case studies. To draw on a range of sources and provide multiple perspectives (Crouch & Pearce, 2012), the data includes websites, Instagram posts, and public interviews. In addition, the researchers used methods of observation and reflection to document their attendance at open studios and observe finished products. The data was analysed in relation to the key processes of sourcing, design, production and retailing to examine the actors involved in each stage. To discuss the influence of the designer, these remanufacturing processes are identified as material supply, redesign, remanufacture and retail to allow comparison across the Sub-brand, Initiative and Residency case studies.

## Case Studies

### *Sub-brand*

A sub-brand is defined here as an offshoot of an existing brand, which produces a variation of the main brand's product to appeal to a slightly different demographic. This case study's Sub-brand (SB) is an offshoot of a not-for-profit streetwear label. The Sub-brand remanufactures pre-consumer waste from their primary brand and other partners, including a multinational (MN) and a Melbourne denim brand (DB) (Table 1).

Reflecting on the data, the Sub-brand brings in partners as material suppliers, who provide them with different garment types within the broader category of casual wear. Designers positioned internally to the Sub-brand redesign these materials, and the Sub-brand contributes

| | Case 1: Sub-brand (SB) | |
|---|---|---|
| | **Case 1a: Multinational (MN)** | **Case 1b: Denim Brand (DB)** |
| **Material Supply** | • MN supplies faulty sportwear garments & excess stock<br>• SB's main brand supplies some stock | • DB supplies factory seconds, samples & excess stock denim garments |
| **Redesign** | • SB selects redesign techniques:<br>  ◦ Splicing<br>  ◦ Placement prints<br>  ◦ Patching<br>• SB applies design details:<br>  ◦ Contrast stitching<br>  ◦ Printed SB logo & recycling symbols in contrasting colours, often over spliced seams or existing logos<br>  ◦ Raw edges | • SB designer selects redesign techniques:<br>  ◦ Splicing<br>  ◦ Tie-dyeing<br>  ◦ Placement prints<br>  ◦ Patchwork<br>  ◦ Patching<br>• SB applies design details:<br>  ◦ Exposed contrast overlocking<br>  ◦ Printed recycling symbols & SB branding in contrasting colours<br>  ◦ Raw edges |

| **Retail** | • SB retails under subsection on the main brand website & instore<br>• SB promotes via specific Instagram account<br>• SB produces imagery | • DB retails instore with some styles available on DB website (profits go to SB cause)<br>• SB produces promotional imagery |

** SB produces one offs although there is clear repetition of some designs.*

**Table 1. Overview of Sub-brand partnerships with a multinational and a denim brand.**

to remanufacturing and retailing stages. While one partner does provide support for the production and retailing, the Sub-brand produces the majority of the images and profits go to their cause, positioning the retailing as occurring within the Sub-brand or shared between the Sub-brand and the material provider partner.

*Initiative*

An initiative is defined here as bringing together activities under an overarching purpose for a forward-thinking project. The Initiative in this second case study was started by an established independent minimalist Melbourne brand (IN) that produces garments offshore. The Initiative encompasses the brand's reuse practices including repair, remanufacturing and resale. Partners are used to implement this Initiative including a social enterprise to repair garments. For remanufacturing, the brand works with an emerging brand (EB) and a niche label (NL), who both have experience with reusing materials (see Table 2).

The data shows in Table 2 how the Initiative is established by the brand, which takes on the role of material supplier, bringing in multiple external designers who redesign and remanufacture their pre-consumer stock. These redesigners draw on their existing design strategies, applying these to the pre-consumer stock. The remanufactured product is retailed in the brand's store, as the redesigner's product, and the redesigners are the primary promoters. The retailing role is therefore positioned as shared.

| | Case 2: Initiative (IN) | |
|---|---|---|
| | **Case 2a: Emerging Brand (EB)** | **Case 2b: Niche Label (NL)** |

**Exact number unknown*
*#Additional projects between IN & EB outside paper scope*

**Table 2. Overview of Initiative partnerships with an emerging brand and niche label.**

### *Residency*

A residency is defined here as the provision of space and facilities over a specific period to enable a design project, linking to how artist residencies in Australia are used to support innovation and experimentation (Lehman, 2017). The Residency examined in this case study is a remanufacturing mini-factory (RE) established in 2021 as part of a construction developer's community project in collaboration with an Australian designer. The mini-factory includes washing, dyeing, cutting, and sewing capabilities, with a few staff including a manager and a machinist. Partner brands participate in ~6 week "residencies" where they work with the inhouse team to produce small runs of remanufactured designs. Table 3 outlines the stages involved and the contributions of the various actors, examining two residencies with different Australian designer brands (DA & DB).

The data shows that the textile waste collector is the material supplier, providing garments for the residency mini-factory to remanufacture. Garments are remanufactured based on the

| | Case 3: Residency (RE) | |

designs developed by external designers who operate as the redesigners, drawing on their existing design practices. The products are remanufactured by the Residency and retailed and marketed through the redesigners' existing brand platforms.

## Designers Shape Remanufacturing

The three partnership structures position roles differently, as can be seen in Figure 1. The roles undertaken by the various actors include the material provider, who supplies the textiles to be remanufactured; the redesigner, who determines what techniques and processes will be applied to these materials; the remanufacturer, who actions these redesigns to produce the remanufactured product; and the retailer, who handles the imagery, marketing, retailing platform and sales. Our discussion focuses on the positioning of the redesigner and whether they are either working internally within the initiating brand or are brought in as external partners.

In the Sub-brand structure, internally positioned designers develop a suite of methods that are sufficiently flexible to be applied to a variety of materials. This is outlined in Table 4, where

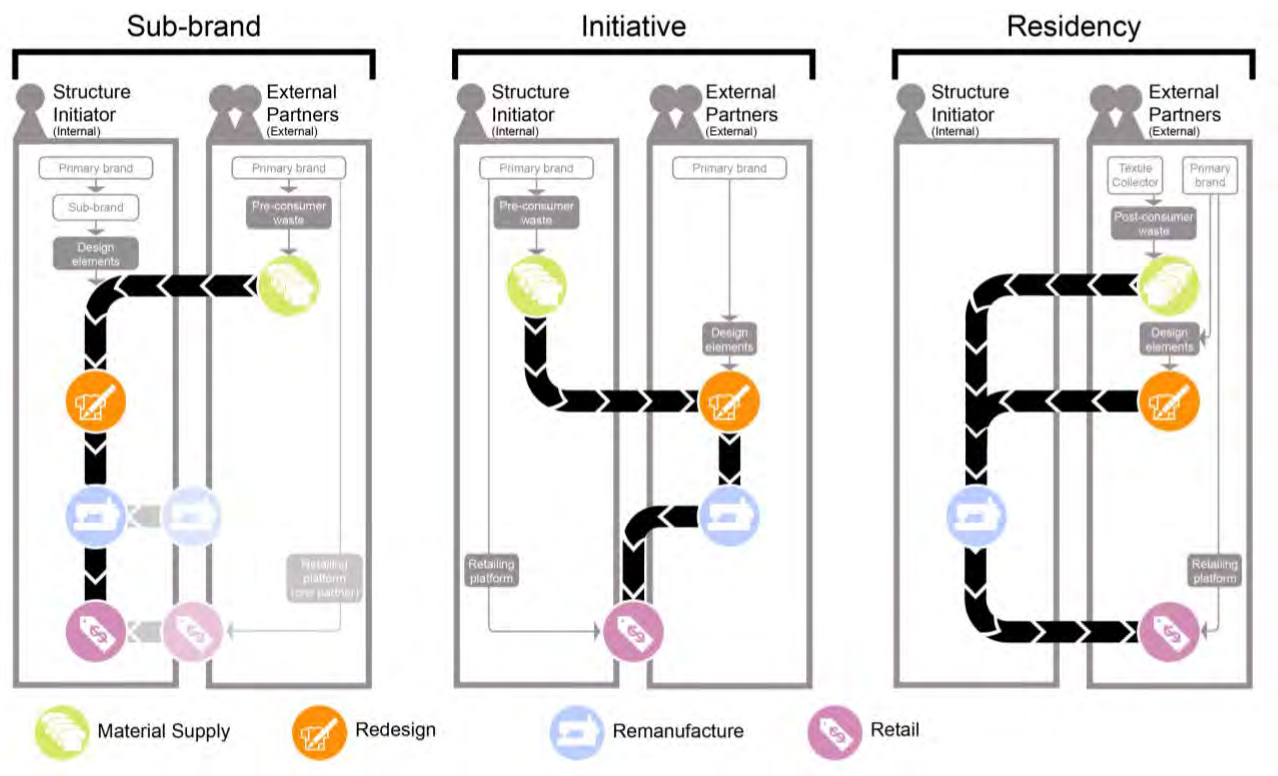

**Figure 1. Diagram comparing three partnership structures.**

| | Sub-brand | Initiative | Residency |
|---|---|---|---|
| **Sourcing inputs** | *Varied (external)*<br>• Multiple brands<br>• Pre-consumer garments | *Consistent (internal)*<br>• same brand<br>• pre-consumer | *Varied (external)*<br>• Post-consumer denim<br>VS<br>• Post-consumer shirting & bedding |
| **Design elements** | *Consistent (internal)*<br>• Colours<br>• Logos & symbols | *Varied (external)*<br>• Balanced<br>VS<br>• Asymmetric | *Varied (external)*<br>• Silhouettes |
| **Remanufacturing techniques** | *Consistent (internal)*<br>• Splicing<br>• Placement printing<br>• Patching | *Varied (external)*<br>• Splice<br>VS<br>• Patchwork | *Varied (internal)*<br>• Dis/re-assembly via patterns<br>VS<br>• Tie-dyeing, splicing |
| **Marketing & Promotion** | *Consistent (internal)*<br>• In-house visuals & promotion | *Varied (shared)*<br>• Promoted separately by each redesigner<br>• Retailed through initiative platform | *Varied (external)*<br>• Each redesigner creates visuals and retails on own platform |
| **Final Products** | **Consistent**<br>(with some variety) | **Varied**<br>(with some similarity) | **Varied** |

**Table 4. Pattern of product outcomes across the 3 remanufacturing structure**s.

consistent design elements such as colours and logos are applied through techniques including printing and splicing, harmonising and branding the remanufactured products. This ties to existing research on standardisation, where methods are developed that the remanufacturer applies repetitively (Pal et al., 2021; Weber, 2019). The consistent use of these design elements and techniques is the method through which the Sub-brand develops its brand identity.

Designers can also be positioned externally, as seen in the Initiative and Residency structures. In these cases, their redesign approaches reflect their pre-existing practices, leading to products that closely align with their own brands. In the Initiative, this is evident in the redesigners' use of techniques developed through their own brands, for example garment splicing or patchworking, resulting in varied outcomes, despite both using input material from the same brand (see Table 4). In the Residency structure, the material inputs are varied, as are the use of design elements and remanufacturing techniques. For example, one redesigner tie-dyes plain weave textile products and fashions them into loose flowing and gathered garments, whereas the other reassembles jeans into tailored silhouettes via structured pattern cutting. Despite the diverse outcomes across both the Residency and Initiative, the products remain aligned to each redesigner's aesthetic.

This alignment between the redesigner and the final product is present across all the partnerships, whether the designer is internal or external. This is supported by how the redesigners are consistently involved in the marketing and retailing, either as the only retailer or through sharing this role with the material suppliers (Figure 1).

Our research shows that over the course of multiple partnerships, redesigners can generate either continuity of products when internal, or variety when brought in as external collaborators (see Table 4).

## Conclusions

This paper examined three partnership structures which facilitated remanufacturing practices in Melbourne/Naarm*. The partners undertake the roles of the material supplier, redesigner, remanufacturer and retailer in various combinations, however the methods employed by the redesigners directly link them to the aesthetics of the final product. This reveals that the positioning of the redesigner shapes the remanufacturing outcomes' aesthetics, as when internally positioned they facilitate continuity, while externally positioned designers can generate variety across multiple partnerships.

This paper's focus on geographically co-located cases has been informed by Melbourne's established practices of independent designers and production capabilities (English & Pomazan, 2010). While the paper has relied on publicly available information, the authors acknowledge that further research, including their ongoing PhD research, is needed to provide deeper insights into the relationship dynamics between the partners.

This paper shows the potential for the strategic positioning of the designer in remanufacturing partnership structures to foster diverse ways for brands across multiple scales to engage with fashion remanufacturing.

## Acknowledgments

*Naarm is the traditional Aboriginal name for Melbourne used by the Boonwurung and Woiwurrung language groups of the Central Kulin Nation.

The authors would like to acknowledge the Wurundjeri People of the Kulin Nations as the Traditional Owners of the lands on which this research was conducted. This paper is based on ongoing PhD research projects, 'Collaborations for Remake' by Julia English (supervised by Dr Angela Finn and Dr Rebecca van Amber) and 'RE-kin-DLE, Scalable methods for redesign and remanufacture' by Miriam Borcherdt (supervised by Dr Robyn Healy and Dr Georgia McCorkill). These PhDs are supported by Australian Government Research Training Program Scholarships.

# Understanding the Social Mechanisms behind Sustainable Practices to Extend Clothing Lifespan

**F. Suhendan Eroglu**[a]
a) Department of Industrial Design, Istanbul Technical University, Istanbul, Turkey

**Keywords**: clothing; lifespan extension; user behavior; sustainable practice; social learning; sustainability.

**Abstract**: User behavior has a significant impact on clothing lifespan from purchase to disposal. Extending clothing lifespan as a social practice depends on sociocultural factors that lay the foundations of specific behavioral patterns. It is crucial to reveal the social mechanisms behind sustainable practices to develop lifespan extension strategies with lasting effects. This study aims to understand the interrelation between environment, behavior, and personal state to explore the social mechanisms behind sustainable practices regarding clothing lifespan to determine new intervention points for design practice. An online questionnaire is conducted to collect information about extending clothing lifespan through the following sections: sustainable behavior related to clothing, foundations of sustainable behavior, and obstacles to performing sustainable practice. Guided by Albert Bandura's Social Learning Theory, behavioral patterns throughout clothing lifespan are examined by reviewing the frequency of the behaviors aligned with the R-ladder (refuse, rethink, reduce, reuse/resell, refurbish, re-manufacture, repurpose, recycle, recover/re-mine). The study demonstrates that users tend to acquire sustainable behaviors through observation and interaction while being exposed to people, media (visual or written), and institutions. The ones who have the ability to perform sustainable practices share their knowledge and skills to encourage others. Sustainable practices are dependent on the links established through social learning. Exploring the missing links between the key actors to find possible ways of cultural change will contribute to achieving sustainability at a systemic level.

## Introduction

Early approaches to Design for Sustainability mainly focused on manufacturing processes and technical issues alike. However, starting with Emotionally Durable Design (see. Chapman, 2005), design researchers have begun to acknowledge the significance of user behavior regarding product lifespan. Especially, Design for Sustainable Behavior has brought a new perspective on finding ways to change undesirable user behaviors for sustainable living. However, researchers raised concerns about current DfSB approaches, emphasizing the uncertainty of achieving change on large scales besides a focus on incremental savings and dictating specific actions (Kuijer & Bakker, 2015, p. 221), the dependence on voluntary restraint (Buenstorf and Cordes, 2008, p. 646), the lack of exploration regarding the influence of the social environment (Salazar et al. 2013, p. 173), the detriment of considering broader societal transformation (Shove, 2010), and the lack of engagement with the connections between people and their objects in existing routines, ideas and performance of activities (Hielscher, 2011, p. 48). Furthermore, several researchers stated that pro-environmental patterns of consumption are not dependent on educating or persuading individuals to change their decisions but on modifying current practices for sustainability acknowledging sustainable patterns of consumption as embedded within social practices (Southerton et al., 2004; Warde, 2005; Hargreaves, 2011; Hielscher, 2011).

In this sense, Practice Oriented Approach based on Practice Theory prioritizes practices over individuals and aims for radical changes in current practices. Reckwitz (2002) describes a practice as "a routinized type of behavior which consists of several elements, interconnected to one other: forms of bodily activities, forms of mental activities, 'things' and their use, a background knowledge in the form of understanding, know-how, states of emotion and motivational knowledge." Investigating a behavior as a nexus of several elements brings a deeper understanding of its realization by users. Many researchers have emphasized its crucial role in addressing unsustainable consumption to achieve radical changes (Shove, 2010; Niedderer et al., 2014; Corsini et al., 2019). However, the exclusion of the individual leads to superficial and ambiguous solutions despite its promising aspects. When addressing behavior change, it is crucial to adopt a holistic perspective that takes into account each factor. Social Learning Theory is an appropriate approach as it does not relegate sociocultural factors to the background. Individuals practice, observe and interact; they improve their personal state through learning which enables specific practices; and those practices modify the environment they interact with the affordances which lead to change (Figure 1).

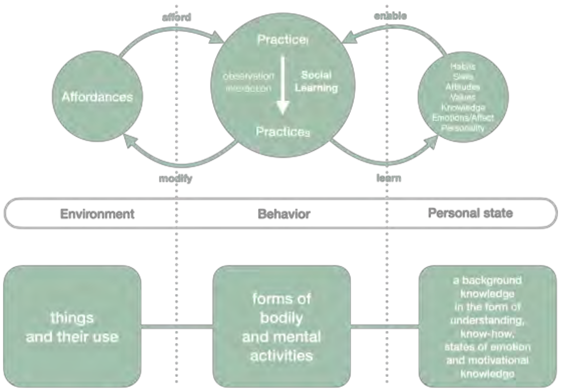

**Figure 1. The Overlap between Social Learning Theory (Bandura, 1977) and Practice Theory (Reckwitz, 2002). © Suhendan Eroglu.**

Kaaronen and Strelkovskii (2020) used an agent-based model elaborating Kurt Lewin's (1950) Behavior Equation: B = f(P, E), to validate it against cycling behaviors, which has proved the emergence of behaviors is a product of personal, environmental, and social factors. Following this approach, behaviors related to extending clothing lifespan are investigated to reveal the interrelation between environment, behavior, and personal state in this study. It is aimed to explore the sustainable practices performed by people from different cultural backgrounds (aligned with the R-ladder) and to find out intervention points to facilitate social learning for sustainability at a systemic level.

## Methodology

The study focuses on clothing, as it is one of the most problematic product categories regarding lifespan. Previous studies emphasize the importance of extending clothing lifespan, however, there is a lack of effort to improve user practices (Niinimäki & Durrani, 2020; Laitala & Klepp, 2020; De Wagenaar et al. 2022).

### *Participant Profile*

Convenience sampling is employed to choose participants. For a more consistent outcome, it was considered that the same number of people from each age group would participate. An online questionnaire is conducted using Google Forms in three languages: Turkish, English, and Japanese. 54 people participated in the questionnaire. Demographics are given below (Table 1).

| Total sample size (n=54) | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Age (Avg. 37.9) | | | | Gender | | Nationality | | |
| 18-29 | 30-42 | 43-57 | 58-75 | Female | Male | TR | JP | DE |
| 18 | 17 | 17 | 2 | 37 | 17 | 38 | 15 | 1 |

| Place of residence | | | | | | |
|---|---|---|---|---|---|---|
| Turkey | Japan | Germany | Spain | Italy | Switzerland | USA |
| 33 | 14 | 2 | 2 | 1 | 1 | 1 |

**Table 1. Demographics.**

### *Procedure*

The questionnaire consists of six sections in the following: I (Demographics), II (Personal Perspective), III (Sustainable Behavior Related to Clothing), IV (Foundations of Sustainable Behavior), V (Obstacles to Perform Sustainable Practice), and VI (Your Sustainable Practices). In Section I, participants were asked about their nationality, age, gender, location, and occupation. In Section II, to measure the general tendency of the sample size, six items are included questioning whether the participants (i) are familiar with the term "sustainability", (ii) worry about global warming and climate change, (iii) have heard about Sustainable Development Goals (SDGs), (iv) believe that future generations will not be able to meet their needs due to a lack of natural resources, and (v) their attitude about environmental problems (level of activity), and (vi) their level of adaptation to a sustainable lifestyle. In Section III, items related to sustainable behaviors aligned with R-ladder are adapted from De Wagenaar et al. (2022). Using a five-point Likert scale (1: Never, 5: Always), the frequency of the sustainable behaviors (Table 2) is investigated to reveal the routinized ones.

| Item | Content | R-Strategy |
|---|---|---|
| 13 | I rather buy less. | Refuse |
| 14 | I buy second hand. | Rethink |
| 15 | I buy high quality timeless items. | Rethink |
| 16 | I buy items with recycled materials. | Reduce |
| 17 | I prefer swapping instead of buying. | Reduce |
| 18 | I reuse items (hand-me-down clothes). | Reuse/resell |
| 19 | I perform better washing practices by following the washing and care instructions. | Reuse/resell |
| 20 | I lease/rent garments. | Reuse/resell |
| 21 | I sell/donate garments for reuse. | Reuse/resell |
| 22 | I repair/get repaired garments. | Repair |
| 23 | I use carefully. | Refurbish |
| 24 | I alter/get altered garments to better suit style/size. | Remanufacture |
| 25 | I upcycle garments to other purpose than clothing. | Repurpose |
| 26 | I dispose/donate for recycling. | Recycle |
| 27 | I dispose in household waste. | Recover/re-mine |

**Table 2. Sustainable behaviors aligned with R-ladder.**

In Section IV, participants are asked about their environment, behavior (social learning), and personal state to reveal the interrelation between these three factors (Table 3). Affordances are specified as regulations, facilities/services, and products/tools. In Section V, participants are asked about the obstacles that disable them to perform sustainable practices with regard to Environment, Behavior, and Personal State. In Section VI, participants were expected to answer an open-ended question: “describe the sustainable practice(s) you perform in daily life and explain why you perform them. (Refuse, Reduce, Reuse, Repair, Repurpose, Recycle, etc.)”. Participation was not high enough in Section VI, therefore the data was not eligible for conducting an analysis.

| Item | Content | Factor |
|---|---|---|
| 28 | My environment has changed, which led me to behave more sustainably. | E |
| 29 | Specific regulations in my environment enable me to perform sustainable practices. | |
| 30 | Specific facilities/services in my environment enable me to perform sustainable practices. | |
| 31 | Specific products/tools in my environment enable me to perform sustainable practices. | |
| 32 | If I change my environment, I can live more sustainably. | |
| 33 | New regulations…<br>New facilities/services…<br>New products/tools…<br>will enable me to perform sustainable practices. | |
| 34 | The people…<br>The media (visual or written)…<br>The institution(s)…<br>I got exposed to in the past influenced me to acquire specific sustainable behaviors. | B |
| 35 | I am exposed to sustainability issues more than ever, so my behavior has changed compared to the past. | |
| 36 | I get exposed to sustainable practice(s) through my family, friends, and/or social circle. | |
| 37 | Observing other people…<br>Interacting with other people…<br>provides me clues to behave sustainably. | |
| 38 | I feel the urge to change my behavior to live sustainably when I observe and interact with people. | |
| 39 | I have abilities/skills that enable me…<br>I share my knowledge and skills to encourage people…<br>to perform sustainable practices. | |
| 40 | I influence how my social circle behaves sustainably. | |
| 41 | My sustainable practice(s) will change the environment that surrounds me. | |
| 42 | I adjust my sustainable behavior(s) according to my personal state. | P |
| 43 | My physical environment<br>My social environment<br>…influences my personal state. | |
| 44 | I improved my personal state through interaction/observation to perform sustainable practices. | |
| 45 | My personal state enables me…<br>I cannot afford to change my personal state…<br>to perform sustainable practices. | |

**Table 3. Sustainable behaviors aligned with R-ladder.**

Reliability and correlation analyses of the collected data are conducted through SPSS 28. Cronbach's Alpha is 0.795 for 60 items of the questionnaire, which is acceptable. KMO Test (Kaiser-Meyer-Olkin Measure of Sampling Adequacy) confirmed that the sample size was adequate (0.704).

## Results

### *Sustainability Awareness*

Participants work at a company or an institution that strives to achieve sustainability (Item 6) were only 18 out of 54 people. 9 people out of 18 were from Japan. Sustainability awareness was relatively high among the participants (Table 4).

| | I am familiar with the term "sustainability." | Global warming and climate change make me worry. | I have heard about Sustainable Development Goals (SDGs). | Future generations will not be able to meet their needs due to a lack of natural resources. | What is your attitude about environmental problems? | Have you adapted well to a sustainable lifestyle? |
|---|---|---|---|---|---|---|
| % | Item 7 ≥3 | Item 8 ≥3 | Item 9 | Item 10 ≥3 | Item 11 ≥3 | Item 12 ≥3 |
| Group 1 (TR) n=36 | 97,2 | 100 | 66,7 | 97,2 | 89,9 | 96,1 |
| Group 2 (EN) n=3 | 100 | 100 | 100 | 100 | 100 | 100 |
| Group 3 (JP) n=15 | 40 | 86,7 | 60 | 86,7 | 100 | 80 |
| Total n=54 | 79,07 | 95,57 | 75,57 | 94,63 | 96,63 | 92,03 |
| Avg. Out of 5 | 3,79 | 4,41 | 3,67 | 4,11 | 3,80 | 3,32 |

**Table 4. Sustainability Awareness.**

### *Sustainable Behavior Related to Clothing*

The results showed that buying less, performing better washing practices, selling/donating garments for reuse, using carefully, and disposing/donating for recycle can be considered routinized behaviors (Table 5).

| | Refuse | Rethink | | Reduce | | Reuse/resell | | | | Repair | Refurbish | Remanuf. | Repurpose | Recycle | Recover/re-mine |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| % | Item 13 ≥3 | Item 14 ≥3 | Item 15 ≥3 | Item 16 ≥3 | Item 17 ≥3 | Item 18 ≥3 | Item 19 ≥3 | Item 20 ≥3 | Item 21 ≥3 | Item 22 ≥3 | Item 23 ≥3 | Item 24 ≥3 | Item 25 ≥3 | Item 26 ≥3 | Item 27 ≥3 |
| Group 1 (TR) n=36 | 86,1 | 33,3 | 72,2 | 55,6 | 13,9 | 47,2 | 95,4 | 5,6 | 86,1 | 89,9 | 97,2 | 93,3 | 96,1 | 91,6 | 13,9 |

| Avg. Out of 5 | 3,67 | 1,83 | 3,15 | 2,46 | 1,69 | 2,19 | 3,85 | 1,22 | 3,67 | 3,67 | 4,33 | 3,46 | 3,39 | 3,63 | 1,80 |

**Table 5. Sustainable behavior related to clothing.**

Although there is sustainability awareness, these concerns do not show a positive correlation with less consumption. This revealed that although users are aware of sustainability, they are not active in reducing consumption. In addition, unlike other parameters, it is seen that the participants abstain from buying second-hand clothes (Item 14), swapping items (Item 15), and renting clothes (Item 20).

### *Clothing practice: Interrelations between Environment, Behavior, and Personal State*

Participants agreed with all items regarding Environment factor on clothing practices. The demand for new facilities/services and new products/tools were higher than for new regulations (Table 6).

| | My environment has changed, which led me to behave more sustainably. | Specific regulations in my environment enable me to perform sustainable practices. | Specific facilities/services in my environment enable me to perform sustainable practices. | Specific products/tools in my environment enable me to perform sustainable practices. | If I change my environment, I can live more sustainably. | New regulations will enable me to perform sustainable practices. | New facilities/services will enable me to perform sustainable practices. | New products/tools will enable me to perform sustainable practices. |
|---|---|---|---|---|---|---|---|---|

| **Item 32** | | **Item 14, 16, 17, 18, 19, 21, 24, 25, 26** |
| If I change my environment, I can live more sustainably. | ↔ | Rethink, Reduce (2), Reuse/resell (2), Repair, Remanufacture, Repurpose, Recycle |
| **Item 33.1** | | **Item 13, 16, 18, 21, 22, 25** |
| New regulations will enable me to perform sustainable practices. | ↔ | Refuse, Reduce, Reuse/resell, Repair, Repurpose |
| **Item 33.2** | | **Item 13, 14, 16, 17, 18, 21, 24, 26** |
| New facilities/services will enable me to perform sustainable practices. | ↔ | Refuse, Rethink, Reduce (2), Reuse/resell (2), Remanufacture, Recycle |
| **Item 33.3** | | **Item 14, 15, 17, 18, 19, 20, 21, 22, 24, 26, 27** |
| New products/tools will enable me to perform sustainable practices. | ↔ | Rethink (2), Reduce, Reuse/resell (4), Repair, Remanufacture, Recycle, Recover/re-mine |

**Table 7. Positive correlations between Clothing Practice and Environment factor.**

Changes in the environment encourage individuals to behave more sustainably and perform sustainable practices, however, Refuse and Reduce were not correlated with

Item 28. In general, current regulations (Item 29) seem to enable individuals to perform sustainable practices except being unrelated to Refuse and Refurbish. Moreover, current facilities/services (Item 30) also seem to support individuals to perform sustainable practices related to Rethink, Reduce, Reuse/resell, Repair, Remanufacture, Repurpose, Recycle. In addition, current products/tools (Item 31) seem to facilitate individuals to perform sustainable practices through Rethink, Reduce, Reuse/resell, Remanufacture, Repurpose, Recycle, Recover/re-mine. Participants who think that they can live more sustainably if they change their environment (Item 32) are revealed to be practicing the following: Rethink, Reduce, Reuse/resell, Repair, Remanufacture, Repurpose, Recycle. Even though users are actively practicing sustainable behaviors, there is a demand for new affordances (Item 33), new products/tools especially. In conclusion, when the environment changes, individuals have the opportunity to perform sustainable practices. According to the correlation analysis, individuals approve that regulations, facilities/services, and/or products/tools change their environment to behave more sustainably, and they believe their sustainable practices influence the change in the environment.

In the next part, it is revealed that being exposed to people in the past enable individuals to perform sustainable practices and those individuals share their knowledge and skills to encourage other individuals to perform sustainable practices (Table 8). This finding supports the socially learned and transmitted nature of sustainable practices. In addition, being exposed to not only people but also media (visual or written) has the influence to change individuals' behavior to make them perform sustainable practices.

**Table 8. Behavior factor on clothing practice.**

The activity of observation and interaction are deliberately investigated as Heyes (1994) describes social learning as "learning that is facilitated by observation of, or interaction with, another individual (or its products)". Individuals who get exposed to sustainable practice(s) through their family, friends, and/or social circle obtain clues to behave sustainably through observation and interaction; observation and interaction urge individuals to change their behavior to live sustainably (Items 37-38). Positive correlations between Clothing Practice and Behavior factor are presented in Table 9.

| Positive correlations between Clothing Practice and Behavior factor | | |
|---|---|---|
| **Item 34.1** The people I got exposed to in the past influenced me to acquire specific sustainable behaviors. | ↔ | **Items 13-24 and 26** Refuse, Rethink (2), Reduce (2), Reuse/resell (4), Repair, Refurbish, Remanufacture, Recycle |
| **Item 34.2** The media (visual or written) I got exposed to in the past influenced me to acquire specific sustainable behaviors. | ↔ | **Items 14, 15, 16, 19, 21, 22, 24, 25 and 26** Rethink (2), Reduce, Reuse/resell (2), Repair, Remanufacture, Repurpose |
| **Item 34.3** The institution(s) I got exposed to in the past influenced me to acquire specific sustainable behaviors. | ↔ | **Items 13, 15, 16, 20, 23 and 26** Refuse, Rethink, Reduce, Reuse/resell, Refurbish, Recycle |
| **Item 35** I am exposed to sustainability issues more than ever, so my behavior has changed compared to the past. | ↔ | **Item 14, 16 and Items 18-26** Rethink, Reduce, Reuse/resell (4), Repair, Refurbish, Remanufacture, Repurpose, Recycle |
| **Item 36** I get exposed to sustainable practice(s) through my family, friends, and/or social circle. | ↔ | **Item 14, Items 16-22 and Items 24-26** Rethink, Reduce (2), Reuse/resell (4), Repair, Remanufacture, Repurpose, Recycle |
| **Item 37.1** Observing other people provides me clues to behave sustainably. | ↔ | **Items 13-19, Item 22 and Items 24-26** Refuse, Rethink (2), Reduce (2), Reuse/resell, Repair, Remanufacture, Repurpose, Recycle |
| **Item 37.2** Interacting with other people provides me clues to behave sustainably. | ↔ | **Item 14, 18, Items 21-22 and Item 27** Rethink, Reuse/resell, Remanufacture, Recover/remine |
| **Item 38** I feel the urge to change my behavior to live sustainably when I observe and interact with people. | ↔ | **Items 14-19 and Items 21-26** Rethink (2), Reduce, Reuse/resell (3), Repair, Remanufacture, Recycle, Recover/re-mine |
| **Item 39.1** I have abilities/skills that enable me to perform sustainable practices. | ↔ | **Items 13-16 and Items 18-26** Refuse, Rethink (2), Reduce, Reuse/resell (4), Repair, Refurbish, Remanufacture, Repurpose, Recycle |
| **Item 39.2** I share my knowledge and skills to encourage people to perform sustainable practices. | ↔ | **Item 13, Items 15-16 and Items 19-26** Refuse, Rethink, Reduce, Reuse/resell (3), Repair, Refurbish, Remanufacture, Repurpose, Recycle |

| **Item 41** My sustainable practice(s) will change the environment that surrounds me. | ↔ | **Items 14-26** Rethink (2), Reduce (2), Reuse/resell (4), Repair, Refurbish, Remanufacture, Repurpose, Recycle |

**Table 9. Positive correlations between Clothing Practice and Behavior factor.**

Furthermore, those individuals who have skills and knowledge to share, and they influence their social circle (Items 39-40). The findings suggest that individuals tend to observe people; on the other hand, they tend to interact with media and institutions to obtain clues for sustainable practices. Also, being exposed to sustainability issues has a positive influence on social learning to perform sustainable practices.

In the next part, the results showed that the social environment has more influence on personal state compared to the physical environment. This finding is important because 93,50% of participants stated that they adjust their sustainable behavior(s) according to their personal state.

| | I adjust my sustainable behavior(s) according to my personal state. | My physical environment influences my personal state. | My social environment influences my personal state. | I improved my personal state through observation to perform sustainable practices. | I improved my personal state through interaction to perform sustainable practices. | My personal state enables me to perform sustainable practices. |

**Table 11. Positive correlations between Clothing Practice and Personal State factor.**

Depending on the practice, individuals improve their personal state through either observation or interaction. Individuals seem to improve their personal state through observation slightly more than interaction which enables them to perform sustainable practices. However, both of them influence the personal state.

Improving personal state through interaction is related to Environment factor. It implies that social learning enables individuals to adopt sustainable practices when they are provided with a suitable environment (regulations, facilities/services, and/or products/tools).

### *Obstacles to Performing Sustainable Practice*

In this section, it is revealed that most of the participants (73,33%) think their environment is an obstacle to performing sustainable practices. Regarding affordances, the unavailability of facilities/services and products/tools are more prominent than the unavailability of regulations. It can be inferred that despite the regulations, other environmental factors can pose an obstacle to sustainable practices (Table 12).

| | My environment is an obstacle for me to perform sustainable practices. | [illegible] | [illegible] | [illegible] | My social circle is an obstacle for me to perform sustainable practices. | [illegible] | [illegible] | My personal state is an obstacle for me to perform sustainable practices. | [illegible] | [illegible] | [illegible] | [illegible] |

**Table 12. Obstacles to performing sustainable practice.**

Positive correlations between Clothing Practice and Obstacles are presented in Table 13. The correlation between Items 13-27 and Items 46-51 revealed the relationship between practices for extending clothing lifespan and the obstacles to performing those practices. Item 46 positively correlated with eight practices (Items 15, 16, 19-24, 26). The environment may pose an obstacle for specific behaviors but not for others. Furthermore, Item 48 positively correlated with twelve practices (Items 14, 16-26). It can be assumed that individuals still try to perform sustainable practices, despite the social circle being an obstacle.

**Table 13. Positive correlations between Clothing Practice and Obstacles.**

## Conclusions

Social learning plays a significant role in encouraging sustainable practices, as individuals who are exposed to sustainable practices through their family, friends, and social circle obtain clues to behave sustainably through observation and interaction. They can then share their knowledge and skills with others in their social circle, facilitating behavior change. While institutions may not play a significant role in social learning to initiate behavior change, individuals may still interact with media and institutions to obtain clues for sustainable practices. Also, being exposed to sustainability issues facilitates social learning to perform sustainable practices. Behavior factor influences personal state factor. Individuals construct and improve their personal state through social learning. In conclusion, social learning has the potential to influence the spread of sustainable practices on a wide scale.

Each factor (Environment, Behavior, Personal State) influences each practice at different levels. For instance, even if the regulations encourage people to perform a specific sustainable behavior, there is still a need for services/facilities or products/tools to make them routinized. The influence of the factors on specific practices must be clearly understood to develop strategies for sustainable behavior change. Especially, non-routinized behaviors such as buying second-hand, swapping, and renting should not be overlooked.

The limitations of the study are listed in the following. Extending clothing lifespan is taken as a practice in this study; however, it can be analyzed in small parts focusing on a specific behavior pattern (reuse, recycle, etc.) on R-ladder. Reuse, recycle or another one can also be considered as a practice to investigate for more pertinent findings. The uneven number of participants from different cultural backgrounds was a barrier to measuring cultural differences while performing sustainable practices. Japanese participants' average age was lower compared to the whole, which may have created an inaccurate representation of the tendencies of Japanese people.

For further studies, it is crucial to investigate the affordances (regulations, facilities/services, products/tools) provided by the environment, focusing on social learning through specific cultural contexts, to reveal their role in facilitating social learning. How can design facilitate social learning through products or services? How to connect people to provide opportunities to observe and interact? Designing environments that facilitate social learning might contribute to long-lasting sustainable behavior change. Besides, the role of social networks can also be investigated concerning the adoption of sustainable practices and how information spreads through social networks to create behavior change.

## Acknowledgments
I would like to express my sincere gratitude and appreciation to all participants who supported me during the study.

# User Influence on Product Lifespan: A Case Study of Toys based on Material Qualities

**F. Suhendan Eroglu**[a]
a) Department of Industrial Design, Istanbul Technical University, Istanbul, Turkey

**Keywords**: Product lifespan; Toys; Sustainable consumption; Materials.

**Abstract**: Lifespan optimization has an important role in sustainable consumption. Although it may appear that designers can generally anticipate product lifespan throughout the design process, users have a significant impact on product lifespan that cannot be accurately predicted without observing their interactions with the product throughout its lifespan, phase by phase. Therefore, it is important to analyze the product lifespan in every phase that the product is acquired, utilized, possessed, and disposed of by the user. First, the product category must be identified to conduct the lifespan optimization strategies systematically. Durable goods (such as home appliances, furniture, etc.) rather than throw-away goods (such as food, detergents, etc.) are the main subject of these strategies. Small work or personal care appliances, mobile phones, pagers, and toys are relatively short-lived products compared to other durable goods. In this research, toys are selected in this product category to be investigated, because they have remained unexplored previously. User influence on product lifespans regarding toys is studied based on the product characteristics determined by the material of the product. The interactions of the user with the product throughout the product lifespan are explored in relation to the material qualities. The results present how different qualities of various materials influence the way the product is utilized by the user and, consequently, the product lifespan.

## Introduction

To encourage sustainable consumption, it is important to look at how people use products every day and how they interact with them. These interactions shape the lifespan of the product and the product's part in the user's daily life. Needless to say, the product cannot determine its lifespan. Therefore, it is clear that the user has the primary influence on the product lifespan. This brings about a necessity to break down product lifespan into specific phases and to observe user tendencies in every phase that gives clues about sustainable behavior for product lifespan optimization. Evans and Cooper (2010) created a taxonomy of consumer influences on product lifespans and determined the components of each phase of the consumption process. The factors affecting consumer influences on product lifespans are identified and categorized (pp. 323-324). It is revealed that users show an inconsistent attitude at different stages of product-life span regarding sustainable consumption (p. 330). It became evident that product lifespans are often not being optimized and progress to sustainable consumption is consequently being hindered due to consumer behavior across the stages of acquisition, use, and disposal (p. 345). Therefore, sustainable behaviors in each stage should be assessed, and product characteristics that encourage sustainable use throughout the product lifespan should be analyzed to obtain useful data for product lifespan optimization. It is important to find out how the product is utilized by the user at each stage and how this utilization affects the disposal of the product to be able to design products with long lifespans in the future. This study investigates the influence of users on product lifespan based on product characteristics determined by material qualities. The research questions are: (1) How do user behaviors change over the course of product lifespan depending on the material used? (2) Which materials are the most effective ones to achieve sustainable consumption through product lifespan? (3) Is there a correlation between certain materials and replacement decisions?

## User influence on product lifespan

It is a priority to acknowledge the user's role which is crucial to product lifespan. Evans and Cooper (2010) state that it is essential to understand the influence of user behavior on product lifespans thoroughly to make good progress in sustainable consumption (p. 319). The designer is supposed to consider what will happen during the lifespan of the product; this includes ”looking ahead during product development to anticipate user demands, future possibilities, and potential problems” (Van Nes, 2010, p. 129). Moreover, the use stage also enables designers to have the chance to directly influence behavior through lifestyles and consumption. Designers can educate consumers to behave more responsibly thanks to this opportunity (Bhamra and Lofthouse, 2007, p. 45). Evans and Cooper (2010) created a taxonomy that revealed consumer influences on product lifespans (Table 1). How product lifespans are affected by users in each phase of consumption is explained.

| Consumption process | | Influences on product life, by phase |
|---|---|---|
| Components of acquisition phase | Desire | Timing of acquisition (i.e. prompt) |
| | Search | Nature of search process (e.g. impulse/ researched)<br>Source of acquisition (e.g. new/used) |
| | Criteria formation | Requirements prioritised (e.g. desired quality) |
| | Moment of acquisition | Anticipated lifespan of product |
| Components of use phase | Usage | Commitment to product care |
| | Storage | Modes of storage |
| | Consultation of manual | Adherence to guidelines/instructions |
| | Maintenance | Regularity of maintenance |
| | Product evaluation | Anticipated future lifespan/satisfaction |
| | Product obsolescence | Commitment to repairs/alternative uses |
| Components of disposal phase | Problem recognition | Timing of disposal (i.e. prompt) |
| | Product assessment | Condition of discarded product |
| | Moment of disposal | Disposal option selected |

**Table 1. Taxonomy of consumer influences on product lifespans. Adapted from Evans and Cooper (2010).**

As it is shown in Table 2, significant influence upon lifespans (of footwear, large kitchen appliances, and upholstered chairs) is exerted by users at each stage of the consumption process (Evans and Cooper, 2010, p. 326).

| Acquisition phase |
|---|
| • Acquisitions of everyday footwear and upholstered chairs are often prompted by relative obsolescence rather than product failure.<br>• Many acquisitions occur without people evaluating their existing possessions, due to impulse purchases and special offers, which leads to products being accumulated or discarded prior to failure.<br>• Few people pro-actively seek independent product reviews or consult other sources of information prior to making acquisitions.<br>• Most people do not consider long life expectancy (or associated attributes such as reliability and ease of maintenance) a high priority in acquisition. |
| **Use phase** |
| • Product negligence is commonplace, especially with everyday footwear.<br>• Most people take a haphazard approach to maintaining product quality.<br>• Repair and other activities that rejuvenate products are rarely undertaken.<br>• Some people who carefully maintain products do not take measures to extend their lifespans when worn or broken, while others who seek to extend lifespans at the disposal stage do not treat products with care in use. |
| **Disposal phase** |
| • Many people discard upholstered chairs in ways that enable their continued use, but few acquire second-hand products.<br>• Many people discard products on the grounds that they are worn, but few mitigate the process of deterioration during use. |

**Table 2. Summary of consumer influences, by phase of consumption**.

## Product lifespan optimization

Extending the lifespan of a product is a critical issue in sustainable design. However, lifetime optimization as a strategy is relatively ”underexposed, both in theory and in practice.” The very limited number of product examples available proves the practical underexposure (Van Nes and Cramer, 2006, p. 101). First of all, product lifespan optimization requires the identification of the product category. It is important to identify the category of the product under examination to engage in environmental strategies efficiently (Vezzoli and Manzini, 2008, p. 68). Product categories are defined below (Table 3).

Previous studies in the UK and the Netherlands, respectively (Cooper, 2005; Wang et al., 2013), revealed that small work or personal care appliances, mobile phones and pagers, and especially toys (shorter than four years) are the most short-lived products in the durable goods category. It is stated that ”design solutions are needed to postpone replacement, using strategies such as designing products for reliability and robustness, repair and maintenance, upgradeability, product attachment, and variability" (Van Nes, 2010, p. 107).

| Product Categories | |
|---|---|
| **Consumer Goods (throw-away goods)** | **Durable Goods (reusable goods)** |
| 1. Goods that become used up, like food or washing powder:<br>- no need to design them to be more durable but minimizing their resource consumption is important<br>2. Throw-away goods that can be reused, recycled or substituted, such as packaging, newspapers and throw-away razorblades:<br>- with products with greater impact during the production and disposal stage it could be fruitful to extend their lifespan by substituting with other reusable goods or by making them reusable | 1. Goods that consume little or no resources while in usage:<br>- impact occurs mainly during the (pre-)production, distribution and disposal stages<br>- minimizing the resource impact and consumption of production and distribution activities is important<br>- impact of disposal can be minimized by extending the material lifespan, but frequently it is more efficient to extend the product lifespan, especially in cases of cultural obsolescence<br>2. Goods that consume resources and energy during use and maintenance:<br>- the extension of lifespan might be questionable that there are more important other strategies, particularly reduction of their resource consumption |

**Table 3. Product Categories. Derived from Vezzoli and Manzini (2008, p. 68).**

End-of-life strategies need more attention. "Not because this stage has an extra high environmental impact, but because at this stage the manufacturers and designers are less involved than at any other" (Vezzoli and Manzini, 2008, p. 69). Supporting that, "design knowledge on product life extension strategies (longer product life, reparability, refurbishment and remanufacturing) and product recycling is currently underdeveloped. These strategies need to be tailored to the specific product at hand with the generic waste management hierarchy (prevention, reuse, recycling) providing only limited guidance" (Bakker et al., 2014).

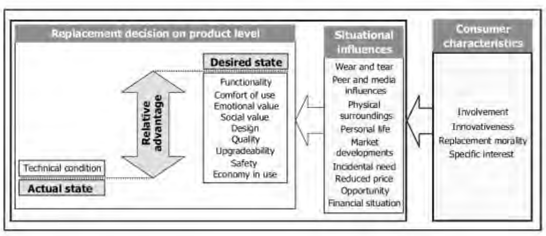

**Figure 1. The factors influencing product replacement decisions. Adapted from Van Nes (2010).**

The responsibilities of the consumer during a product's life cycle (i.e. the phases of acquisition, use, and disposal) have received not enough attention (Evans and Cooper, 2010, p. 320). As stated by Van Nes and Cramer (2003) the product lifetime is a result of a user's decision, and not a predetermined design criterion (p. 101). Therefore, in determining product longevity, consumers have a significant role (Evans and Cooper, 2010, p. 322). "A user decides on replacing a product at the moment that the gap between actual state and desired state increases to a certain threshold (i.e. when the advantage of a new product over the one in possession is large enough)" (Van Nes, 2010, p. 110). The factors influencing product replacement decisions are shown in Figure 1.

There are three main factors influencing product replacement decisions that are directly related to lifetime optimization. The first one is the product characteristics refer to those aspects of the product that provide an added value to one product over another. The second one is situational influences or external influences which are factors extrinsic to the product, meaning working from outside and not a part of the essential nature of the thing. The last one is the consumer characteristics refer to those differences between people that explain why, in the same situation, different people make different choices (Van Nes and Cramer, 2003, p. 102).

It is necessary to create awareness among users that their influence on product lifespans is significant to achieve sustainable consumption. Evans and Cooper (2010) stated that "consumers need to be made more aware of long-term consequence of products not realizing their full potential lifespans and to be encouraged to incorporate life cycle thinking into their consumption practices" (p. 343).

## Methodology

Toys are selected as the specific product to be investigated in this paper that even though being one of the short-lived durable goods, it was not studied particularly in previous research. Material is one of the most important qualities of the product that determines its characteristics. Therefore, it is obvious that product characteristics determined by material will affect user behaviors that have a huge impact on product lifespans at each stage.

A questionnaire is conducted to collect information about the relationship between product life and the material of the product. In the first part of the questionnaire, the user profile of the participants concerning sustainable consumption is investigated, and their perceived influence of the material on product life is assessed. Ten people were surveyed by questionnaire, and information about approximately 30 products was gathered through open-ended questions. Demographic information for the participants is summarized in Table 4.

| | |
|---|---|
| **Total sample size** | 10 |
| **Gender** | |
| Male | 2 |
| Female | 8 |
| **Age** | |
| 18-27 | 5 |
| 28-40 | 2 |
| 41-50 | 3 |

**Table 4. Summary of demographic information.**

Participants were asked to indicate if they consider themselves conscious of sustainable consumption on a five-point scale of ‘no’ to ‘yes’. %80 of the participants without doubt considered themselves conscious of sustainable consumption (Table 5).

| **Do you consider yourself conscious of sustainable consumption?** | | | | |
|---|---|---|---|---|
| No | Improbably | Maybe | Probably | Yes |
| %0 | %0 | %20 | %40 | %40 |

**Table 5. Participant profile.**

In the following questions, participants were asked to give information about the influence of materials of toys on their decision of acquisition, way of use, and decision of disposal. As shown in Table 6 a large percentage of the participants stated that the materials of toys influence each stage of the product life.

| How influential do you think the materials of toys on your; | Not at all | Slightly | Moderately | Very | Extremely |
|---|---|---|---|---|---|
| **decision of acquisition?** | %0 | %0 | %40 | %20 | %40 |
| **way of use?** | %10 | %10 | %0 | %60 | %20 |
| **decision of disposal?** | %20 | %10 | %10 | %30 | %40 |

**Table 6. Perceived influence of the material of toys on product life.**

Qualitative and quantitative data are collected through a questionnaire with people who had acquired or replaced a toy at least once in the past fifteen years. Participants were asked to give information about the product life spans of the toys, naming at least one short-lived and one long-lived product that they had used before. Eight of the ten participants introduced at least three products made of at least two different materials. Product name, product material, product lifespan information, and consumer behavior in each phase of product lifespan are investigated.

Product lifespan information for thirty-three toys made of six different materials in total is collected. The numbers are summarized by the responses of each participant in Table 7.

| Material | Plastic | Wood | Paper | Fabric | Metal | Glass | Combined |
|---|---|---|---|---|---|---|---|
| Participant 1 | 2 | - | 1 | 1 | - | - | 1 |
| Participant 2 | 2 | - | - | 1 | 1 | - | 1 |
| Participant 3 | 3 | - | 2 | - | - | - | 1 |
| Participant 4 | 1 | 1 | - | 2 | - | - | - |
| Participant 5 | 2 | 1 | - | - | - | - | - |
| Participant 6 | 3 | - | - | 1 | - | 1 | - |
| Participant 7 | 2 | 1 | - | - | - | - | - |

## Results and Discussion

The results of the study are presented in this section. Distinctions between user behaviors during the product lifespan according to the products made of different materials are revealed. The most effective materials to achieve sustainable consumption through product lifespan and the correlation between certain materials and the replacement decisions of the users are discussed. In light of the data obtained from thirty-three products made of six different materials, variations in user behaviors and decisions and duration of the product lifespans are categorized by material. The results of the study are summarized as follows:

Product lifespan in plastic products varies according to the quality of the material. It is revealed that users generally acquire products that they think they can use for a longer period by choosing products made of high-quality plastics. Since plastic is considered a durable material, there has been no tendency to perform any maintenance or repair on the products. The smell of plastic toys is also important for the user and influences the product lifespan. User influences on product lifespan at each stage for plastic toys are summarized in Table 8.

| | Plastic |
|---|---|
| **Acquisition** | When purchasing the product, it is ensured that the material is of high quality and durable. It is expected that high-quality plastic products will have a long life. There are also products acquired as gifts - these are also expected to be long-lasting. |
| **Use** | Most of the products were in line with expectations and had long lifespans. The products did not require special care or maintenance, but it was stated that some products were wiped and cleaned at certain intervals and their original condition was preserved. It was mentioned that some products could not be repaired (squishy toys and smelly dough). Some products have repairability. Certain parts of some products may be used for other functions. |
| **Disposal** | Products like Lego and Barbie dolls are kept in hand for over 20 years. Due to relative obsolescence, some products are given to others for re-use. Products that have lost their function have been thrown away (such as non-recyclable plastics: play dough and squishy toys). |

**Table 8. User influences on product lifespan at each stage for plastic toys.**

The product lifespan of plastic toys varies depending on the material quality and functionality as indicated in the table below (Table 9). It is revealed that eight of the twenty-one products can be used for ten years or more. Most of the products with a life span of five to ten years did not lose their functions, but they were handed down to other users by the first users for re-use due to relative obsolescence. Therefore, it can be assumed that they have a longer product lifespan than that.

| Product life span | |
|---|---|
| **Duration (Years)** | **Sample size** |
| <1 | 5 |
| 1-5 | 3 |
| 5-10 | |
| | 6 |
| 10-20 | 2 |
| >20 | 6 |

**Table 9. Product life span of plastic toys**.

It is seen that wooden products also trigger an expectation that they will have a long life from the users' perspective. Being a natural product and its durability are important factors in this regard. No extra care has been shown for the wooden products by the participants. User influences on product lifespan at each stage for the wooden toys are summarized in Table 10.

| | Wood |
|---|---|
| **Acquisition** | When purchasing the product, it is ensured that the material is of high quality and durable. It is preferred because it is natural/additive-free. |
| **Use** | No special care or maintenance is needed. |
| **Disposal** | No wear is detected. It is in use and can be given to someone else. At the end of its product lifespan (due to relative obsolescence), it will be stored for other people. |

**Table 10. User influences on product lifespan at each stage for wooden toys.**

The product-life span durations of wooden toys are shown below (Table 11). The sample size of the wooden toys is smaller than the plastic toys. However, all products have product lifespans longer than five years.

| Product life span | |
|---|---|
| **Duration (Years)** | **Sample size** |
| <1 | - |
| 1-5 | - |
| 5-10 | |
| | 2 |
| 10-20 | - |
| >20 | 1 |

**Table 11. Product life span of wooden toys.**

No long product lifespan expectancy for paper toys is mentioned by participants. Since most toys in this category consist of board games, the only thing the user can do to extend the product life is to keep the product in its box. User influences on product lifespan at each stage for paper toys are summarized in Table 12.

| | Paper |
|---|---|
| **Acquisition** | Any specific expectation was not mentioned when purchasing the product. |
| **Use** | No special care or maintenance is needed. Being stored in its box or case. |
| **Disposal** | In good condition. It is in use and can be handed down to someone else. In case of relative obsolescence can be re-used. |

**Table 12. User influences on product lifespan at each stage for paper toys.**

Paper toys can also be used for more than five years when carefully stored, as summarized in Table 13.

| **Product life span** | |
|---|---|
| **Duration (Years)** | **Sample size** |
| < 1 | - |
| 1-5 | - |
| 5-10 | 2 |
| 10-20 | 1 |
| >20 | - |

**Table 13. Product life span of paper toys.**

It is revealed that a large percentage of fabric toys have a long life expectancy. Particularly because products acquired as gifts are stored with extra care, a significant impact on product life has been observed. Moreover, the washability of the fabric also has a positive effect on product life through easy maintenance. In addition, sewing provides easy repair, which prolongs the product lifespan. User influences on product lifespan at each stage for fabric toys are summarized in Table 14.

| | **Fabric** |
|---|---|
| **Acquisition** | Some products acquired as gifts. They are thought to be long-lasting. There are also products purchased with the expectation of a long lifespan (Participant 4 - hand puppet). |
| **Use** | Washability of the product has a positive effect on product lifespan. In case of any damage, it is possible to repair it by sewing. At the end of its product life, it is available for decorative use. |
| **Disposal** | It was in good condition to hand over to someone.<br>In case of relative obsolescence can be used as a toy for pets. |

**Table 14. User influences on product lifespan at each stage for fabric toys.**

Most of the fabric toys have product lifespans longer than five years, as summarized in Table 15.

The sample size of metal and glass toys was too small to include in the results section. However, both of them had product lifespans longer than ten years.

| **Product life span** | |
|---|---|
| **Duration (Years)** | **Sample size** |
| <1 | - |
| 1-5 | 1 |
| 5-10 | 2 |
| 10-20 | 1 |
| >20 | 4 |

**Table 15. Product lifespan of fabric toys.**

The comparison of the product lifespans of toys made of different materials is shown below (Table 16).

| **Life span** | **Sample size of toys made of different materials** | | | | | |
|---|---|---|---|---|---|---|
| **Duration (yrs)** | **Plastic** | **Wood** | **Paper** | **Fabric** | **Metal** | **Glass** |
| <1 | 5 | - | - | - | - | - |
| 1-5 | 3 | - | - | 1 | - | - |
| 5-10 | 6 | 2 | 2 | 2 | - | - |
| 10-20 | 2 | - | 1 | 1 | 1 | 1 |
| >20 | 6 | 1 | - | 4 | - | - |

**Table 16. The comparison of product lifespans by material.**

## Conclusions

It is seen that the user has a significant influence in the three stages (acquisition, use, and disposal) of extending the lifespan of the products. Users' tendencies to acquire products made of durable materials that are easy to repair, and require no maintenance with the expectation of a longer product lifespan play a major role in ensuring that the products do not lose their function until the disposal stage. Although products are disposed of due to relative obsolescence, the majority of users who participated in this study showed sustainable consumption behavior by handing down the products to other people who could reuse them.

The more durable the material the product is made of, the more users use the product without the need for care or maintenance. Although plastic or wood products do not require any treatment for a longer lifespan, it is observed that fabric products are treated with washing or sewing for extended product lifespans. Besides, products made of relatively less durable materials, such as paper, are usually stored in boxes and protected for a longer lifespan.

The findings of this study would benefit designers during the material selection stage in the design process for more sustainable products. It is recommended that designers promote sustainable consumption by selecting materials that are durable and easy to maintain. Because toys made of these kinds of materials encourage sustainable consumption among users, even in cases of relative obsolescence (when users dispose of still-functioning products), they tend to hand them down to other users for re-use. On the other hand, manufacturers might intentionally force designers to select low-quality materials to increase product sales. However, recycled materials can be used for products with short lifespans that reduce the environmental impact of disposal. In addition, even products made of low-quality plastics have a potentially long lifespan if they have a secondary function, such as decorative functions, that can be taken into consideration.

As stated at the beginning of the study, the participants in the survey have a higher level of awareness about sustainable consumption than normal people do; this might have affected the product lifespan duration to be relatively longer than usual. The products that the participants mostly mentioned were toys made of plastic and fabric. A larger sample of toys made of other materials is needed to be surveyed for more accurate results. In this survey, a larger percentage of the participants were female users. Due to the differences in usage between male and female users, it is also important to ensure equal participation by men in future studies. Apart from this, some of the participants were people with children, and some of them did not have any children. Different results can be obtained when a more specific target group is selected. Furthermore, the respondents were not selected from a certain economic level. The income levels of the participants may also be determinative of the results. Due to time constraints, survey data were collected both on paper and online.

## Acknowledgments

I would like to express my sincere gratitude and appreciation to all participants who supported me during the study.

# Circular economy and sustainability of cellulosic materials in the clothing industry

**Fiona Ford[a], Dr Claudia E Henninger[a], Dr Alejandro Gallego Schmid [b]**
a) Department of Materials, The University of Manchester, Manchester, England
b) Tyndall Centre for Climate Change Research, School of Engineering, The University of Manchester, Manchester, United Kingdom

**Keywords**: Circular economy; Clothing and textiles; Environmental sustainability; Cellulose; Material recycling

**Abstract**:
Clothing and textiles are the world's third-largest manufacturing industry and one of the most polluting. In the context of the climate emergency, the sector has become the focus of research, investment, and policy towards a circular economy (CE). A CE aims is to mitigate environmental damage by reusing, recycling, and regenerating planetary resources. Cellulose is a prominent clothing material that has received much attention in CE literature and practice. Yet, the literature so far lacks a review of the CE strategies available for cellulosic materials in the sector. The present research addresses this gap, revealing a focus on textile recycling. Recycling is distinguished in terms of open- and closed-loops. In closed-loop systems textile materials are disassembled into fabrics, fibers, or polymers for use in new clothing. Open-loop recycling sees materials used in alternative products or sectors, whereby they typically experience loss in value. The results highlight the importance of closed-loop recycling systems to preserve the value of materials in a CE. New legislation for textile waste collection presents an opportunity for companies to capitalize on post-consumer textiles, the most prominent source of the sector's waste. Advancements in polymer recycling technologies have made them available to this waste stream. These developments have facilitated the growth of high-value closed-loop, textile recycling to the cusp of commercialization, where they show potential to address the sustainability issues associated with existing material lifecycles.

## Introduction

The clothing industry is one of the most polluting on the planet generating 92 million tons of waste per year (Textile Outlook International, 2021). The industry is largely reliant on resource intensive crops and petroleum-based fibers for raw materials. Cellulosic materials are the second most prominent after synthetics, accounting for approximately 40% of all textile production (Textile Exchange, 2021). Increased demand for cellulosic fibers has created a shortfall in supply known as the cellulose gap (Ma et al., 2015). The gap is currently being met by synthetic fibers that are incompatible with natural ecosystems (Björquist et al., 2018; Subramanian et al., 2021).

A circular economy (CE) is proposed to meet market demand for products and materials while mitigating their environmental impact (Ellen MacArthur Foundation, 2013). This is achieved by reusing, recycling, and regenerating the resources embedded in products and materials. Regeneration strategies are designed to sustain or enhance natural capital (Konietzko et al., 2020); reuse focuses on increasing product utilization (Stahel, 1994), while recycling describes operations that contribute to the generation of new products from waste materials (EC, 2008; Stahel, 1994).

Cellulosic fibers are largely derived from plant or manmade sources, with each group carrying negative environmental impact. Cotton is the most common cellulosic material found in clothing (Costa et al., 2022). This low growing crop requires arable land, uses polluting agricultural chemicals, and causes water stress and scarcity (Gullingsrud, 2017; Möhl et al., 2022; Subramanian et al., 2021). Manmade cellulose (MMC) fibers utilize feedstocks from forestry which are dissolved and regenerated with chemicals in energy intensive conditions (Collier & Tortora, 2001). Unlike synthetics, cellulose fibers are soft and breathable, demonstrating similar properties to cotton (Vecchiato et al., 2018). However, demand for forestry feedstocks is increasing as other sectors require the replacement of fossil fuels (Koul et al., 2022).

The cellulosic materials available in clothing are environmentally harmful and unable to meet future demand, therefore require a CE perspective. This study presents a literature and practice review of the CE strategies available to cellulosic materials in clothing. The study will provide an overview of the research area and highlight opportunities for future research.

## Methods

The review aims to scope all CE strategies relevant to cellulosic materials used in clothing. Scopus was searched for articles in English containing titles, abstracts, and keywords with terms 'circular* AND cellulos* AND textil*'. The resulting 101 articles were screened across three criteria. Titles, abstracts, and full texts were screened to exclude articles that address other industries. Secondly, articles were excluded where cellulosic textiles, fibers or yarns did not form an input or output of the CE strategy. This criterion sought to exclude material and energy efficiencies that do not contribute to a CE if applied in isolation (Bocken et al., 2016). Finally, articles that propose the biodegradability of cellulosic materials as a CE proposition were removed if they did not contain a discussion about safety or effects. This criterion was employed to address toxicity issues arising from chemical treatments that can make cellulosic materials polluting when they decompose (Ellen MacArthur Foundation, 2017).

## Results

The search and screening criteria produced a final 37 primary sources focused on material recycling. Recycling is distinguished in terms of open and closed loops. Open-loop scenarios recycle materials in products or sectors that differ from the previous life cycle (Sandin & Peters, 2018). A material's value should be preserved to facilitate continuous circulation within a CE (De Oliveira Neto et al., 2022). The downcycling that occurs in open-loop scenarios make these routes less preferable for clothing waste (Sandin & Peters, 2018). The exception is where agricultural waste is used to produce clothing fibers because value is added to the waste materials (Koul et al., 2022). Since the recycling of agricultural waste does not address the high disposal rates of textiles (Hu et al., 2018), this research will focus on closed-loop recycling. The present study defines closed-loop recycling as the recovery of materials from the textiles industry for use in new clothing. Closed-loop recycling involves waste that occurs either pre- or post-consumer use (Subramanian et al., 2021). Post-consumer waste accounts for the largest percentage of overall textile waste (85%) (McKinsey & Company, 2022), therefore the discussion will focus on this waste stream. The review found several factors affecting the complexity of supply chains in closed-loop post-consumer textile recycling. Post-consumer waste streams are less homogeneous, have higher material integration, and are more likely to be damaged than those occurring pre-consumer (Harmsen et al., 2021; Ruuth et al., 2022; Subramanian et al., 2021). For these reasons it is necessary to include a sorting process in supply chains of post-consumer waste

## Discussion

In Europe, around 38% of post-consumer waste is collected for use in the CE (Van Duijn et al., 2022). The sorting of post-consumer waste separates resaleable textiles from non-reusable items. Since most is sorted manually, around half the waste collected in Europe is outsourced for sorting in countries with cheap labor (Piribauer & Bartl, 2019; Van Duijn et al., 2022). It is estimated that around 40-50% of post-consumer textile waste is not in reusable condition (Piribauer et al., 2021). Non-reusable textiles represent lost revenue to textile sorters due to low recycling rates (Ellen MacArthur Foundation, 2017). This issue is becoming pertinent as the volume and ratio of non-reusable waste is expected to increase (Piribauer et al., 2021; Van Duijn et al., 2022). The use of low grade post-consumer waste in high value closed-loop recycling could overcome the financial challenges faced by textile sorters (Van Duijn et al., 2022). However, the material content must be known in order to engage closed-loop recycling (Harmsen et al., 2021). As material content is difficult to identify by hand the lack of data available about post-consumer waste presents a barrier to recycling (Tyler & Han, 2014). Developments in automated sorting have sought to overcome these limitations (Textile Outlook International, 2021). However, the review uncovered a dearth of studies investigating the environmental impact of textiles sorting operations.

Sandin and Peters (2018) categorize closed-loop recycling by the level of material disassembly. This is implemented at the fabric, fiber, or polymer level. Fabric recycling describes processes that preserve waste fabric in the creation of new products (Sandin & Peters, 2018). Fiber recycling is achieved by the shredding of textiles for the spinning of new yarns (Aronsson & Persson, 2020). Fabric and fiber recycling are typically considered downcycling due to a deterioration in fiber length: a prominent quality indicator in textiles (Sandin & Peters, 2018). Fiber recycling is the most established form of recycling available in textiles (Ribul et al., 2021; Subramanian et al., 2020), yet the application in closed-loop scenarios is limited by the inability to remove contaminants or maintain a consistent fiber length (De Oliveira Neto et al., 2022). Consequently, recycled fibers must be blended with virgin materials to meet commercial expectations . For this reason, fiber recycling is not considered a fully closed-loop process (Ribul et al., 2021).

Polymer recycling is achieved by dissolving waste cellulose, then forming the remaining polymers into new fibers (Harmsen et al., 2021). Some of the technologies are already available at scale for the manufacture of MMC fibers derived from biomass (Määttänen et al., 2019). The dissolving process breaks the polymer chain, leaving it partially degraded (Ribul et al., 2021). The pure cellulose contained within cotton and rayon fibers are less intensive to dissolve than conventional feedstocks (Björquist et al., 2018), while rips and tears occurring from wear can facilitate depolymerization (DP) (De la Motte & Palme, 2018). These aspects make cellulose-containing post-consumer waste textiles a promising feedstock for recycling. When polymers degrade too far the quality of recycled fibers are diminished limiting their consecutive recycling (Ribul, 2021). The effect of multiple rounds of polymer recycling presents a gap in need of further investigation.

Several companies are attempting to commercialize the use of post-consumer textile waste as feedstock for MMC fiber production (Textile Outlook International, 2021). These have developed products to enter supply chains as cellulose fiber, powder, or pulp. Other examples focus on pre-treatments that are licensed to existing manufacturers; allowing them to process post-consumer waste streams.

Lenzing is a producer of MMC fibers known for its market leading Tencel™ lyocell. Manufacturing recovers the process water and N-methylmorpholine-N-oxide (NNMO) solvent in a closed-loop system (Ribul et al., 2021). Lenzing first commercialized the use of post-consumer textiles by introducing 10% into its feedstocks for Refibra™ fibers in 2019 (Textile Outlook International, 2021). The Finnish start-up Ioncell uses ionic liquids (ILs) in their process for MMC fibers from post-consumer cotton. ILs are used to dissolve cellulose at low temperatures, thereby reducing energy consumption and material degradation (Ribul et al., 2021). Unlike NMMO, ILs do not require chemical stabilizers, so are considered less polluting (Asaadi et al., 2017). ILs have the benefit of being able to separate poly/cotton textiles (Haslinger et al., 2019; Haslinger et al., 2017). This process is in use for generating dissolving pulp at demonstration scale with Worn Again Technologies (Mathews, 2018). There are several factors prohibiting the growth of methods by ILs, including: their cost; an absence of closed-loop manufacturing (Elsayed et al., 2020; Ribul et al., 2021); and a lack of industry equipment for spinning at low temperatures; (Shuhua et al., 2020; Subramanian et al., 2021). The high viscosity of spinning dope is another factor, although research has shown this can be overcome with pre-treatments (Haslinger et al., 2019), and industrial filtration (Michud et al., 2016; Parviainen et al., 2015; Sixta et al., 2015; Stepan et al., 2016). The Finnish start-up Spinnova have piloted a solvent free process for the dissolution and spinning of cellulose from a combination of sources (Ribul et al., 2021). The mechanical process is said to have minimal environmental footprint, while materials can be recycled continuously due to the omission of damaging solvents. However, these claims lack peer review at a time when the company are about to commercialize and are beginning to form a supply chain for post-consumer waste (Textile Outlook International, 2021).

Carbamate powder is a cellulose derivative that omits the need for harmful solvents in viscose lyocell production (Textile Outlook International, 2021). The Infinited Fiber Company (IFC) produce carbamate powder from 100% post-consumer textile waste using the processing chemical urea in a closed-loop manufacturing system. The IFC own a pilot scale facility capable of producing 150 tones of fiber per annum and is expected to grow with additional revenue from licensing the technology (Glover, 2022; Textile Outlook International, 2021). The Dutch company Saxcell has developed a dissolving pulp facility capable of producing 25 tones per annum (Saxcell, 2020) and plan to scale following a new round of investment (Björquist et al., 2018). Renewcell's Circulose® pulp has been supplied to viscose and lyocell yarn manufactures since 2019 (Textile Outlook International, 2021). The Circulose® system shreds textiles before adding pre-treatments to purify and solubilize the feedstock (Björquist et al., 2018; Textile Outlook International, 2021). The company have an industry scale pulp production plant in Sweden, capable of producing 60,000 tones per year (Glover, 2022). Their partnership with Bank & Vogue will supply the facility with post-consumer textiles (Textile Outlook International, 2021). A study by Björquist et al. (2018) found that Circulose® lyocell fibers outperformed the market leader, demonstrating superior properties in fibers derived solely from textile waste. The authors (2018) note that, despite the results, decisions over recycled content will likely be guided by economic performance. Yet, a decision-making framework for how much recycled content should be used is so far missing from the literature.

Supply chains for polymer recycling include pre-treatments to open and solubilize textile feedstocks, and remove trims, dyes, and coatings (Björquist et al., 2018; Textile Outlook International, 2021). One of the biggest breakthroughs has been the ability to separate mixed material fabrics (Piribauer et al., 2020; Textile Outlook International, 2021). These projects have concentrated on poly/cotton fabrics, a focus that seems justified by the predominance of these materials in post-consumer textiles (Harmsen et al., 2021; Van Duijn et al., 2022). There have been several processes developed for the separation of mixed composition fabrics. Methods by ILs have already been discussed. Hydrolysis can take place in acidic or alkaline conditions (Björquist, 2017; Palme et al., 2017). Alkaline hydrolysis has shown promise in environmental assessments (De la Motte & Palme, 2018; Peters et al., 2019). The pulp manufacturer Södra, has developed an alkaline hydrolysis process for the separation of cellulose from poly/cotton (Brelid, 2019). The company has partnered with Lenzing in a deal to pre-treat 25,000 tones annually by 2025 (Peterson et al., 2022; Textile Outlook International, 2021). Costa et al. (2022) produced cellulose acetate powder with varying rates of depolymerization by acidic hydrolysis of poly/cotton. Research of the materials performance in yarn spinning, and its implications for manufacturing remained out of scope of the study. Acidic hydrolysis for the separation of poly/cotton materials is also under development in industry (Speight et al., 2020). The technology developed by BlockTexx mixes shredded textiles with aqueous solution, sulfuric acid and water, before it is dried, washed and filtered (Speight et al., 2020). BlockTexx has a facility in Queensland which it will grow to an annual capacity of 10,000 tones by 2024, and plan further expansion with the development of a technology licensing model (Glover, 2022). Hydrothermal methods combine heat, water, and pressure in a in a less polluting and more energy efficient hydrolysis process (Hou et al., 2018). This technique is reported to be in use at pilot scale for the recovery of cellulose for regenerated fibers (Glover, 2022; Textile Outlook International, 2021). However, published studies have so far only managed to recover monomers from the cellulose faction of poly/cotton fabrics (Hou et al., 2018; Matayeva & Biller, 2022).

## Conclusions

The review presents a case for the closed-loop polymer recycling of post-consumer textile waste. This is considered a suitable approach to the sustainability issues of existing materials: the shortfall in supply of cellulose, the environmental costs of virgin materials; and the pollution associated with end-of-life disposal. These technologies have overcome the most prominent limitations of other recycling routes by developing methods to separate contaminants and produce long and regular fibers. Closed-loop polymer recycling offers valorization for textiles that are not in reusable condition, waste-type that is expected to increase. Compatibility with existing manufacturing systems increases scalability, leading several companies to the cusp of commercialisation. At present, the value chains needed to supply textile feedstock to manmade cellulose producers are underdeveloped, and there is a lack of knowledge of their potential environmental impacts. Future studies should consider the impacts of textile collection, logistics and sorting. As the uptake of polymer recycling increases, studies will need to investigate the effects of multiple lifecycles. A study of the decision-making factors involved in selection of waste ratios should also be considered. It is sometimes difficult to distinguish the techniques used in commercial ventures, making it difficult to find peer reviewed evidence to support company claims. For this reason, it is recommended that future research conducts case studies of industry scenarios.

c) Eurecat, Centre Tecnològic de Catalunya, Waste, Energy and Environmental Impact, Manresa, Spain

**Keywords**: Life cycle assessment; Fashion design; Systemic innovation; Circular; Biobased; Local.

**Abstract:** This paper presents interim progress of the HEREWEAR project in developing a method for designing out impacts as part of a collaborative and ongoing process between design researchers, commercial designers and environmental scientists. The aim is to support optimal and iterative decision-making concerning materials and processes, acknowledging their high levels of uncertainty in relation to design choices. This work explores bridging the methodological gaps between environmental science and product development in brands through design research interventions.

## The HEREWEAR project

The HEREWEAR project is a European Union, Horizon 2020 funded project, spanning over 4 years and bringing together 15 different partners. The project explores systemic innovation for biobased, circular, and local fashion. New fibres from agricultural waste are developed in a biorefinery process, made into regenerated cellulose filaments, and into textiles suitable for the partner brand's market. As a highly multidisciplinary collaboration, the perspectives of material scientists, engineers, community activators and designers are combined to offer a holistic view of the challenges in the fashion and textiles industry. Part of the project's aim is to integrate environmental science knowledge in the formative stages of the design decision making process. The environmental assessment will contribute to evaluating the potential of biobased materials, local manufacturing, and circular business models to contribute to decarbonise and reduce the impacts of the industry, and operate a shift to socially just practices.

The team involved in this work includes environmental scientists with experience in eco-design, design researchers, and a fashion brand. Input from other partners in the HEREWEAR project was also gathered at strategic points. The demonstrator used to develop this method is the 'Flexi-Dress', a garment prototype using novel filament fibres from straw waste. As the brand designers and the design researchers collaborate to develop a garment that embodies sustainable and circular design recommendations, they have been seeking advice from the environmental scientists. The iterative process of developing collaborative spaces and tools to enable meaningful exchanges between all parties aims to produce a transferable method for future development and is built upon previous work between UAL and RISE (Earley and Goldsworthy, 2019; Goldsworthy and Ellams, 2019).

## Life Cycle Assessment and eco-design

LCA is a specific methodology of environmental science that offers a quantitative review of the environmental impacts associated with the full life cycle of a product or service. It uses an inventory of data on the energy, materials, transport, etc, and subsequent emissions and wastes allocated to the elements of the product service system (ISO, 2006). Environmental impacts are then calculated within several categories, and in some cases further processed into a single score result (PEF Apparel and Footwear, 2023). Requirements on data and procedure and constraints on usage of results for such a full LCA have increased, and in particular when results are used in external communications with different stakeholders including competitors, transparency and reviews are a crucial element. Other more internal purposes of using data from an LCA study such as choice of materials and production practices might focus on hot-spots and parts of a life cycle and do not have the same constraints as studies involving a wider set of stakeholders with opposing interests. But even in that case, extrapolating and generalising a result can be misleading, as a fabric with low environmental impacts in the production stage and a short lifespan can score better than a more durable alternative. A collaborative process that enables explorative evaluation of potential effects along the life cycle through active discussion at key decision points is recommended.

The LCA method has also been described as falling short of a just representation of the complexity of textile supply chains (Textile Exchange, 2022), albeit without providing alternatives. As LCA requires the data for the full product's lifecycle to be available for full scale production, assessments often come after decisions have been made, offering limited options for revision. This is particularly challenging when the innovation includes new materials and techniques that are only tested in laboratories and pilot plants. Since integration and optimisation is done when scaling up to industry level, resource demand and subsequent impacts of innovative processes tend to be overestimated. Eco-design is defined as "the integration of environmental aspects into product design and development, with the aim of reducing adverse environmental impacts throughout a product's life cycle". Bridging eco-design and LCA was seen as challenging at the time of publishing the global LCA standards in 2006. As put by Millet *et al.* (2007) LCA methods have limited usefulness to the design team. Indeed it "*is limited to an analysis of existing products or well defined products at the final stages of the design process*" (ISO, 2011), and it fails to create a "*learning dynamic*" in companies (Millet et al., 2007).

The HEREWEAR project proposes to challenge these perceived limitations in the design phase by developing a bridge between the LCA and the design team with tools for discussion. It builds on a body of previous research, most notably the Mistra Future Fashion Programme to explore a method for connecting environmental science and design processes into a combined model 'quantified design' that was tested through a set of practice-led developments (Goldsworthy, Roos, Peters and Sandin, 2017; Peters *et al.*, 2018).

## Combined Design/LCA Approaches

Eco-design is put forward as a method that enables the transfer of LCA knowledge and modules into design. Many guidelines have been developed for designers to follow eco-design principles, from generic cross-discipline approaches (Luttropp and Lagerstedt, 2006), to sector-specific ones (Bauer *et al.*, 2018). Important common elements in these methods include the process of transparently defining stakeholders, defining the product, identifying supporting systems, detailed options analysis and synthesising strategy. These approaches were explored by researchers the Mistra Future Fashion Programme, using 'interconnected design thinking' and The TEN in alignment with the Higgs Index (Earley *et al*, 2016:75). The integration of LCA principles and design were tested via the Circular Design Speeds project through a series of design workshops conducted in-house with a fashion brand (Goldsworthy, Earley and Politowicz, 2019; Earley and Goldsworthy, 2019). In particular the bringing together textile design researchers and an environmental scientist working with the brand's in-house team enabled the refinement of circular garment concepts based on projected impacts of design adaptations.

## HEREWEAR Approach

Here the integration of the design research and environmental science methods into a combined process involved the use of a lifecycle map and of garment scenario canvas to facilitate conversations where the research process from each discipline were responsive to one another. Thus, new insights were drawn relating scientifically based environmental impact research to the design process. By integrating these two models circular design is placed at the centre of the design process and backed up by scientific evidence. It is not intended that 'absolute' metric judgements will be made, rather that design decisions will be linked to impacts on a scale which a designer may understand and utilise in their process.

The design work was based on a new set of guidelines named the BIO TEN (Earley and Forst, 2023) adapted from existing circular and eco-design guidelines, in particular The TEN

(Earley and Goldsworthy, 2013), to be made specific to the HEREWEAR pillars of biobased, circular, and local. These guidelines inform the design of the new concept which is reviewed here. The direct discussion between environmental scientists and designers bolsters the decisions supported by the use of the BIO TEN guidelines. The aim of this study is to understand where the quantitative analysis insights can be translated into the detailed decision-making process for a specific garment. This format asks, "is A (generally) better than B from an impact perspective?". Further distinction is often necessary if A is better than B in a defined context, for example when biobased materials are better if they are sourced from waste, organic cultivation practice or specific regions.

## Key Tools for Collaboration

As put forward by Sumter *et al.* (2021), key competencies for design in a circular economy are collaboration and interpersonal skills. It is part of the role of the designer-facilitator to provide the tools for effective collaboration. Two key tools supported the discussion between LCA and design researchers.

### *Lifecycle map*

Using the full lifecycle approach of LCA, the mapping shown in Figure 1 highlights all the different stages of the lifecycle of a biobased, circular, local garment. The development and use of this tool is further discussed elsewhere (Forst and Earley, Forthcoming). Here this visualisation was useful in communicating with environmental scientists on how impacts of material or process choices might be calculated, and guide the development of garment concepts.

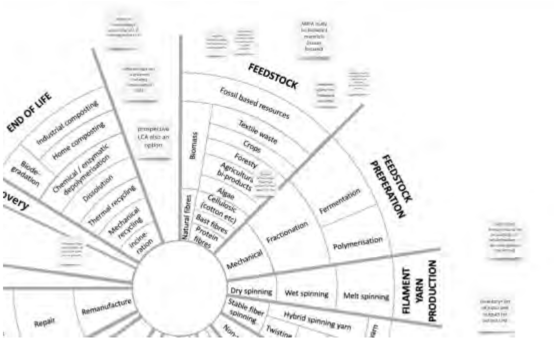

**Figure 1. A screenshot of the lifecycle map tool used in a guided discussion to identify impact hotspots and how they are assessed.**

### *Garment scenario*

Based on the lifecycle map, a format for garment scenarios was developed which accounts for the multiple design decision points available. It asks questions for each stage of the lifecycle to prompt design decisions. This was also used to facilitate cross-disciplinary conversations to identify how features of the product might affect their environmental score. This format provided a holistic view on the full garment system, including business models and associated services, which are key to understanding the potential for a feature such as modularity to have a meaningful impact reduction effect.

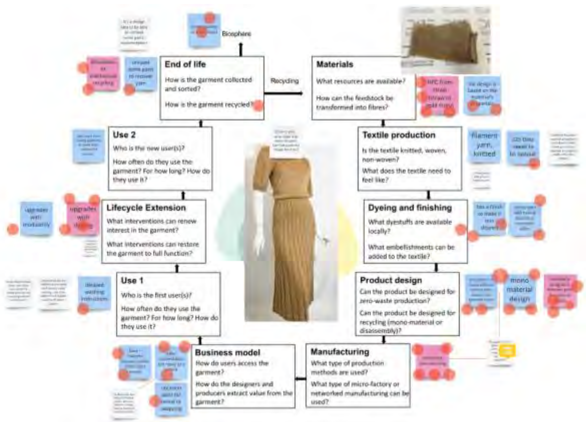

**Figure 2. The garment scenario for the 'Flexi Dress' concept with annotations from a collaborative review.**

## The Lifecycle Design Method

The impact of LCA insights in the design decision making process were reviewed over 3 stages of developing a garment concept. The method followed a Define, Redesign, Refine approach, with each phase here including collaborative discussion and executive decision making. These collaborative design and discussion moments were structured to support the direct sharing of knowledge between disciplines, Matching requirements for the progression of each aspect of the work.

### *Define*

This corresponds to the inspiration and research phase of the design process. The team were asked to provide reference fabrics, existing products from partner brands, and examples of resources and production processes by competitor brands and projects to emulate. Collectively reviewing these elements showed characteristics to benchmark the new garment concepts against. While this “framing the problem” (Cross, 2011) phase is typical of a design process, from an LCA perspective, it sets the reference to calculate the impact savings achieved through redesign decisions.

### *Redesign*

In the redesign phase, speculative garment concepts were developed. This paper focuses on the “Flexi Dress” concept which was based on a new material sample. As opposed to a standard redesign approach, the garment shape and function were extrapolated from the material properties, in particular the lustre of the knitted material. This garment concept draws light to the current limitations of LCA to provide intermediate insights in the design process: as the concept is entirely new and not based on an existing product, the improvements are more difficult to assess and quantify. The concept was built using the garment scenario format. This canvas supported discussion amongst the different technical experts and designers in collaborative workshops online and in person to imagine a full garment lifecycle and weigh the impact of decisions.

### *Refine*

In this phase direct facilitated discussion between environmental scientist and the brand designers helped refine the concept. In the redesign phase, many of the BIO TEN guidelines had been applied to the flexi-dress concept, such as zero-waste pattern cutting, repair, or modularity. Reviews of eco-design approaches have shown that some strategies may be more effective than others in reducing impacts (van Hemel and Cramer, 2002). For a realistic product development, a specific circular design strategy was selected for assessment. The designers questioned the benefit of modularity for this concept. It is foreseen that to enable this feature, then parts of the dress must be designed with an attachment system which could incur more complex manufacturing and more materials, possibly affecting the environmental score.

Designers understand that sustainable and circular design strategies must be approached critically, bearing in mind possible impact shifts, but often this understanding is limited by the unavailability of data and the complexity of measuring impacts across various indicators. One of the challenges of designing in this way is that no strategy is a clear win or loss, and most often the LCA experts’ answer will be “it depends”. Where it is possible to elaborate and clarify on what parameters and factors it depends on this can potentially lead to a valuable dialogue and can be used to iteratively co-create innovative design.

## Challenges of embedding LCA insights in a design process

The methods used in design and in LCA are so different that it is often a challenge to mesh both practices together. The eco-design approach inspires designers to make garments with the potential for longer life and recyclability, but it is generally difficult to objectively measure the benefits of such practices. On the other hand, LCA is the methodology and measurement behind sustainable design, but it if is used to evaluate distinct scenarios and parameterized concepts, it is not suitable as a creative ideation approach. Quantitative assessment of uncertain parameters is well established, but emerging topics for which no data or methods are available cannot be included, known unknowns and unknown unknowns will thus be missed in an assessment. To enable a shift to circular practices, the creativity of designers must be bolstered with evidence for better choices in material, manufacturing process, use, and end-of-life management, with a clear documentation of trade-offs. LCA experts usually perform assessments at the end of the concept development phase, their work involves collecting data from all processes and treatments in the product's lifecycle but can also be carried out for intermediates and preliminary stages. Their experience provides tacit knowledge of how a decision might be weighted in the LCA balance. These qualitative insights from LCA can be useful in conversation as a product concept is developed.

It was therefore valuable to put in place mechanisms like the life cycle design method and tools such as the lifecycle map and the garment scenarios to support conversations between the designers and the environmental scientists throughout the different stages of the decision-making process.

## Conclusions

This paper shows how environmental science expertise can be drawn into key phases of the design decision making process to support the inspiration provided by design guidelines with a product specific follow up. At each of the define, redesign, and refine stages designers can be supported in selecting materials and processes with reduced environmental impacts by nurturing a conversation that balances achieving a desirable design outcome while reducing impacts. Tools that visualise the decision-making process and a garment concept with a full lifecycle approach were found to be useful in nurturing these conversations. The research carried out in the HEREWEAR project has demonstrated the potential for qualitative LCA insights to be used in the design process without waiting for the garment concept to be fully defined to perform an assessment. In the next phases of the research, full assessments will be made for the final version of the Flexi Dress concept and others to measure the effect of the lifecycle design approach.

# Everyone does it: Product-related Resell Strategies of Professional Second-hand Retailers

**Lea Becker Frahm[a], Linda Nhu Laursen[a], Christian Tollestrup[a]**
a) Department of Architecture, Design, and Media Technology, Aalborg University, Aalborg, Denmark

**Keywords**: Resell strategies; Second-hand products; Second-hand shop; Product lifetime; Design for circular economy.

**Abstract**: Today, second-hand businesses, play an increasing role in prolonging product lifetime and postponing product obsolescence through circularity. Currently, research on circular consumption is nevertheless still limited (van Dam et al., 2020). While the resell and reuse of products is still a 'niche phenomenon' (Wilts et al., 2021), the mere existence of second-hand businesses, including private retro shops, charity shops, and shops at municipality recycling stations illustrates, the acquisitions of products does not have to be from the first cycle of consumption (Gregson & Crewe, 2003). In this paper, we research second-hand shops, as we argue these are important to contribute knowledge on how to support circular consumption and increase the lifetime of products in use. Through observations at second-hand shops (n=20) and semi-structured interviews (n=11) with different types of second-hand retailers, we identify six cumulative resell strategies used to sell second-hand goods. These strategies include: 1) pricing, 2) cleaning, 3) research brand, 4) renew or restore, 5) repurpose or upcycle, and 6) identifying the history.

## Introduction

In today's 'throwaway society' product lifespans are decreasing, resulting in numerous negative environmental side effects (Cooper, 2005). One way to counteract this is by turning towards a circular economy (MacArthur, 2013). Research on circular economy related to industrial design contains production processes, circular consumption, support policies, and design education. Among these, research on the upstream matter (circular production processes) is the largest, whereas knowledge on downstream aspects such as circular consumption is more limited (van Dam et al., 2020; Camacho-Otero et al., 2018).

In this paper, we conduct a study on circular consumption by examining second-hand markets. The existence of second-hand markets stresses the acquisitions of goods do not have to be from the first cycle (Gregson & Crewe, 2003). While second-hand markets are important in the transition to circular consumption patterns, today, the reuse of products is still considered a 'niche phenomenon' (Wilts et al., 2021). Second-hand markets exist because consumers are open to reusing products (Gregson et al., 2013). Thus, we argue these must be studied to contribute valuable knowledge to support a circular economy.

## Sales approaches in second-hand markets

Many types of second-hand markets are found in literature, such as charity shops, private retro shops, and shops at municipal recycling stations (Bohlin, 2019; Gregson & Crewe, 2003). Through different practices retailers of second-hand goods add value to their products, thus, transforming products into becoming desirable again (Baker, 2012). In the literature, we identify three product-related approaches of second-hand retailers:

### *Market knowledge*

Retailing second-hand requires knowledge of what is sellable, hence the current trends. Despite knowing which product, they can (and cannot) sell, retailers of second-hand must also know the other actors selling second-hand, and what they sell. (Parsons, 2005)

### *Rituals of divestment*

Well-known in the literature about second-hand products is the 'fear of contamination' (Baxter et al., 2016; Baxter et al., 2017; Wallner et al., 2021; Mugge et al., 2017). Purchasing second-hand usually requires more work from the consumer compared to the conventional purchasing experience. The coping strategy to this contains e.g., cleaning, repairing, and personalizing second-hand products (Gregson & Crewe, 2003).

*History*
Naturally, second-hand products are in their second, or more cycle of usage, leaving the products with a 'history' that either decreases or increases their value (Parsons, 2005). Studies have observed a transaction of product history in second-hand markets: sellers tell how the product has been used, and by whom, and the buyers listen carefully and add how they plan to use and take care of the product (Bohlin, 2019; Herrmann & Soiffer, 1984).

## Methods

This study focuses on second-hand retailers (B2C) as we argue these have the incentive to develop and refine their sales strategies, hence are a best-case scenario to learn from. Thus, we exclude cases of consumers selling to other consumers (C2C), which also entails commission sales, auction houses, flea markets, garage sales, and online platforms.

The data include observations at 20 second-hand shops and interviews with 11 second-hand retailers in Denmark. Thus, informants are selected based on expectations about information content (Flyvbjerg, 2006).

An interview guide was made based on initial observations and conversations with second-hand retailers. The semi-structured interviews lasted 1-1,5 hours and took place in the workplaces of the interviewees, allowing the interviewer and interviewee to point out products for discussion during the interviews (Kvale & Brinkmann, 2015; Brinkmann & Tanggaard, 2020). Photos were taken of the objects discussed for later reference. The interviews were audio-recorded, transcribed, and a qualitative analysis of the content was completed.

## Findings

Through analysis we identify 11 resell strategies within six overall categories (table 1):

| | **Product-related resell strategies** | **Informant #** |
|---|---|---|
| **Market knowledge** | **Pricing**<br>1) Fixed prices on product categories<br>2) Minimum prices on specific brands<br>3) Individual assessment<br>4) Specialists'/ informants' advice<br>5) Price adjustments | **1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11** |
| | **Research brand** | 1, 2, **3, 4, 5, 6, 7**, 8, **9, 10, 11** |
| **Rituals of divest-ment** | **Cleaning**<br>1) Standardized cleaning routine<br>2) Specialized cleaning | **1**, 2, **3, 4, 5, 6, 7**, 8, **9, 10, 11** |
| | **Renew or restore**<br>1) Renew<br>2) Restore | 1, 2, **3**, 4, **5, 6, 7**, 8, **9, 10, 11** |
| | **Repurpose or upcycle**<br>1) Repurpose<br>2) Upcycle | 1, 2, 3, 4, **5, 6**, 7, 8, 9, **10, 11** |
| **History** | **Identify the history**<br>1) History of the product category<br>2) Product-specific histories | 1, 2, 3, 4, **5, 6**, 7, 8, 9, **10**, 11 |

**Table 1. Overview of findings in relation to theory. Black bold numbers in the informant column inform the frequency of reselling strategies.**

*Market knowledge*
Two overall strategies related to market knowledge have been observed: 'pricing' and 'brand research'.

**Pricing**
Five differing pricing strategies have been identified to assess the right price for second-hand products.

**1) Fixed prices on product categories**: The fixed prices were often applicable for the product categories that were sold in great numbers, e.g., drinking glasses, cutlery, shoes, books, etc. A volunteer at a charity shop says:

*“Regular books, clothing, shoes, and so on have fixed prices, except a few ones, which we think are special, but that depends on who is adding the price tag.”* – Informant #4

**2) Minimum prices on specific brands**: To consider that some brands are more expensive than others in the first cycle of purchase, some shops have lists of what they assess as valuable brands and hence their minimum prices. Some larger charity organizations also provide pricing courses for their employees, as explained by a volunteer:

*“We get courses in pricing from someone in the organization. They tell us what is trending and what it should cost, and show pictures of the stamps we should look for at porcelain and so on”* – Informant #4

**3) Individual assessment:** Other second-hand shops assess every single product to find a price. Thus, pricing becomes a matter of expertise and discussing with other employees/volunteers if in doubt, or online research. A leader of a charity shop tells:

*"We agree on the prices. If we are in doubt, we search for it online. Den Blå Avis (online resell platform) has many things for sale"* – Informant #1

Further, many private retro retailers have a rule of thumb saying that their selling price should at least be four times the purchasing price.

**4) Specialists’/informants’ advice:** Second-hand retailers report how they learn from others how to assess the prices. Moreover, some use volunteers/employees with expertise from previous jobs, such as jewelers, and hence they assess the price of all jewelry. Customers and other resellers also influence the pricing by letting our informants know when they priced something “wrongly”. Thus, with time they develop their pricing skills. Exemplified by a volunteer at a charity shop:

*“I saw an ‘Eric Kold’ plastic container like this one in a retro shop recently, and that was 50dkk, so I think ours should be a little cheaper.”* – Informant #4

**5) Price adjustments:** Many private retro retailers within this study tell how they experience lowering the price is not always the solution to get something sold. Independently from one another, they explain that increasing prices can make hype and increase the experienced value of a product. A private retro retailer tells:

*”One thing I cannot sell for 500dkk, but I can sell it for 1.000dkk, and other things cannot be sold for 500dkk, but only for 200dkk. (…) ‘If it’s more expensive, it must be exclusive’“*– Informant #5

**Brand research**
Some second-hand retailers research almost all their products, while others only do it with very few items. This information is often written on price tags, signs, and on social media posts (see figure 1). A private retro retailer explains:

*“I search a lot for things online, when I am in doubt whether the items have a name (designer, etc.). Everyone within this kind of business does it. That is the nicest when selling something.”* – Informant #10

**Figure 1. Sign with the name, year of design, designer, and manufacturer. Photo from a private retro shop.**

*Rituals of divestment*
Three streams of rituals of divestment have been observed: 'cleaning', 'renew or restore', and 'repurpose or upcycle'.

**Cleaning**
Through our studies we identified two levels of cleaning:
**1) Standardized cleaning routine:** Many shops have a standardized cleaning routine, where e.g., all cutlery, cups, and porcelain are washed in the dishwasher, and clothing is washed and ironed. Some charity shops explain how they are trying to get rid of prejudices that charity shops are dirty and smell bad. A leader of a charity shop tells:

*"All clothing gets sorted, washed, and ironed, and all glassware and porcelain go in the dishwasher. (…) One of our volunteers washes the dolls and does their hair."* – Informant #1

**2) Specialized cleaning:** Cleaning of products in relation to what causes the dirtiness. Assessments on whether it can be cleaned are also a factor when private retro retailers buy for their shop. A private retro retailer explains how she with time has developed expertise in assessing whether a product is irreparably destroyed or can be cleaned:

*"With time I have learned how to distinguish between something that is just very dirty, and something devastated before I purchase. (…) I know how to remove a layer of nicotine, and how to clean silver tin without ruining it."* – Informant #11

**Renew or restore**
Renewing or restoring is a matter of either looking ahead or back in time.

**1) Renew:** By renewing the products second-hand retailers seek to increase the aesthetic value of a product, by e.g., painting or upholstering. Many argue that it requires lots of money, practice, and expertise. Hence some only accept products, that do not require any renewal. A private retro retailer tells:

*"In the beginning, I paid an upholsterer, but the cost was too high, so I started doing it myself. It takes some practice, but it is getting better and better"* – Informant #9

**2) Restore:** Restoring second-hand products is about re-establishing the intended look and hence value. Some highlight how they seek to bring back products to their original condition, as they feel it is disrespectful to e.g., paint or upcycle them. Instead, they seek to show the value of how the products were intended to be. Exemplified by a private retro retailer:

*"When I buy a wooden table and see that the painting is not made by the factory, I always remove it. Sometimes it is mahogany that people paint! (…) I'll always try to get the products back to their original."* – Informant #11

**Repurpose or upcycle**
Repurposing and upcycling both seek to make use of second-hand products. Repurposing does not require any adjustments but concerns a new use of a product, while upcycling requires physical changes of a product to support a new usage.

**1) Repurpose:** Some display their repurposing ideas in their shops and on social media. Many emphasize the importance of during so, as customers often cannot imagine how to style or use a product differently. A private retro retailer tells and shows (figure 2) how they demonstrate new purposes and underlines that they always find a purpose for their products before purchasing:

*"They are meant to be in a vase, making sure the flowers stand nicely. That's what they were designed for, but we use them for brushes, pencils, incense sticks, or knitting needles. We find a way to use things, and it makes a difference. Some people cannot get those ideas by themselves"* – Informant #10

**Figure 2. Repurpose of flower fakir. Photo from a private retro shop.**

**2) Upcycle:** Products with obsolete functionality are turned into new products to keep them relevant and usable. E.g., we found multiple private retro retailers purchasing antique wallpaper printing rollers and turning them into lamps (figure 3)

**Figure 3. Antique wallpaper printing rollers. The one to the right is upcycled into a lamp. Photo from a private retro shop.**

### *History*

**Identify the history**

In some second-hand retailers, we found sellers spend much time identifying the histories, in two aspects:

**1) History of the product category:** Providing the history of product categories is used to increase value. Further, a retro retailer tells how wear-and-tear can become valuable when customers get to know the story:

*"Back in the days, dough dishes were used when you drew blood for blood sausage, and you had to whisk it to prevent the blood from coagulating. Some of these dough dishes have been used for generations, resulting in a hole in the glazing where the whisk touched. To some people it is ugly, but I also sell them due to the story"* – Informant #10

**2) Product-specific histories:** Several retro retailers make a virtue of gathering information about their products, and some even prefer to buy from privates to get the 'extra value' the stories offer. A private retro retailer says:

*"We sell history just as much as we sell goods. We tell the story of where the products come from and that helps sell them. When buying from privates, we always ask for the story. E.g., this cabinet is from a police station, and you can see where the guns were."* – Informant #5

## Discussion

The six identified product-related sales strategies do not occur with equal frequency. Some are commonly reported by informants, while others are only deployed at more 'high-end' or specialized second-hand retailers. Our study indicates the strategies are more or less advanced, hence some resell strategies require more knowledge, resources, and expertise, and are only deployed by a few, such as 'identifying the history', whereas 'pricing' is performed by everyone.

Looking at the frequency of the resell strategies, our study shows an advancement based on the knowledge and resource investment level of the retailer. In figure 4, each blue circle refers to a strategy performed on a product by second-hand retailers. The strategies are cumulative, meaning the pricing is the 'easiest, performed by all' where the larger the circle, the more of the six activities are performed.

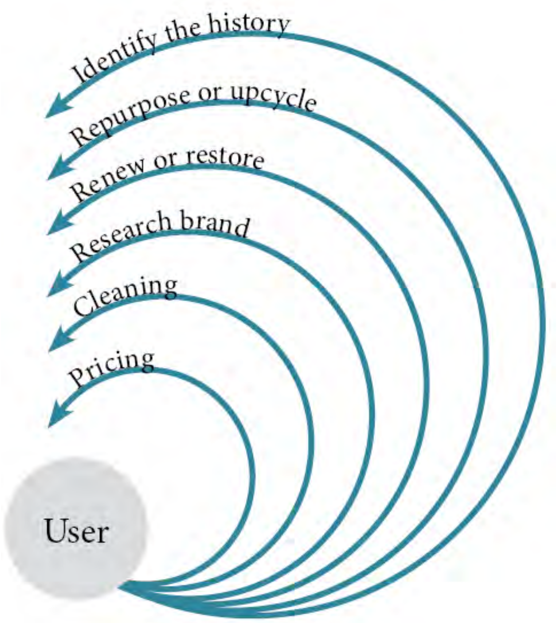

**Figure 4. Accumulative strategies performed on products by second-hand retailers.**

By studying the resell strategies of second-hand retailers the existing literature has been nuanced, and six product-related strategies have been identified. However, as it has not been a focus of this research, we cannot conclude whether one resell strategy is more successful than the other, nor can we elaborate on the consumers' perspective on these strategies. Thus, we suggest more research on this topic.

Another study found three post-purchase rituals of consumers regarding second-hand products with similarities to some of our identified product-related resell strategies. Them being recovery rituals, divestment rituals, and transformative rituals (Gregson & Crewe, 2003). This indicates that some second-hand retailers perform activities, that otherwise would be required of the consumer to do. Thus, we suggest future studies of lead users in second-hand shopping, to explore whether they perform currently unknown activities, that can be adopted by second-hand shops, and hereby support the reuse of products.

This study indicates that private retro retailers, in general, perform more resell activities, compared to e.g., charity shops. The reason for this may be, that the private retro retailers depend on their own ability to sell products to pay rent, purchase new products, and pay their own wages. Yet, we have no insight into the economy and number of sales of these second-hand shops, and thus we cannot determine whether the increased number of resell activities pays off. Another explanation, often expressed by volunteers at charity shops, is that they lack time, money, and expertise. However, conversations at charity shops have revealed, that individual volunteers sometimes have ideas for e.g., repurposing the products. Yet not even one of the repurposing ideas has been observed demonstrated in any of the visited charity shops. These ideas have only been revealed through conversations. Thus, this indicates a potential, that is not yet realized.

## Conclusion

This study contributes to the nuance of existing literature on resell strategies and identifies six product-related resell strategies performed by second-hand retailers. The cumulative product-related resell strategies are: 1) pricing, 2) cleaning, 3) research brand, 4) renew or restore, 5) repurpose or upcycle, and 6) identify the history. This knowledge is valuable to understand the mechanisms of second-hand markets, circular economy, and hence extending product lifespan.

# Smells Like Grandparents: Consumers' Barriers and Motivations to Second-hand Shopping

**Lea Becker Frahm[a], Linda Nhu Laursen[a], Casper Boks[b]**
a) Department of Architecture, Design, and Media Technology, AAU Aalborg University, Aalborg, Denmark
b) Department of Design, NTNU Norwegian University of Science and Technology, Trondheim, Norway

**Keywords**: Consumer barriers; Consumer motivation; Second-hand shopping; Second-hand products; Design for a circular economy.

**Abstract**: Consumers' perspectives on the reuse of products are crucial to understand for supporting and achieving a circular consumption and economy. While second-hand products are still a niche phenomenon (Wilts et al., 2021), second-hand markets validate the consumers' willingness and desire to reuse products (Gregson & Crewe, 2003). To accommodate the call for knowledge on consumer behavior regarding the circular economy, this study investigates consumers' motivations and barriers to shopping in second-hand markets. The research includes 20 semi-structured interviews with a diverse set of informants to ensure rich data (Kvale & Brinkmann, 2015). With the departure in existing knowledge about barriers and motivations to second-hand shopping from literature, the authors have, based on analysis of the interviews, identified, and categorized seven additional barriers and five motivations, which have not yet been described in the literature. The motivations concern aspects such as social-, quality-, and design aspects, whereas the barriers mostly relate to the shopping experience and the social aspects. Thereby this study builds on prior studies and extends the theoretical understanding of the different aspects of second-hand shopping, that can either enhance or worsen the experience.

## Introduction

Consumers demand new products at an increasing frequency, resulting in an ever-decreasing lifespan of products (Cooper, 2005). To reverse this trend, one may investigate the model of circular economy, where a central aspect is slowing down consumption loops. Slowing loops means extending or intensifying the use period of products, so resources may remain at their highest value for as long as possible (MacArthur, 2013). E.g., as heirlooms (Frahm et al., 2022) or second-hand products (Gregson & Crewe, 2003).

While design for a circular economy has received an increasing amount of attention in research during the past ten years (van Dam et al., 2020; Boks, 2018), the consumer perspective of sustainable behavior has received proportionally less attention in comparison to e.g., circular production methods (Camacho-Otero et al., 2018; van Dam et al., 2020). However, several researchers emphasize the importance of understanding user behavior and motivation in the specific context of circular value offerings (Daae et al., 2018). They argue that the circular economy can hardly exist (Hobson & Lynch, 2016; Ackermann, 2018; Jackson, 2005; Bhamra et al., 2011). Current literature covers some consumer motivations (e.g., (Guiot & Roux, 2010)) and barriers (e.g., (Edbring et al., 2016)) to second-hand shopping. Nevertheless, to our knowledge, a comprehensive categorization of motivations and barriers to second-hand shopping is not available in the literature. Thus, this study aims to nuance and develop an understanding of this, by answering the research question: What are consumers' barriers and motivations to second-hand shopping?

## Methodology

Two methods have been used: 1) a literature review to collect barriers and motivational factors, and 2) semi-structured interviews to gain additional insights which could complement and help to further develop existing literature.

To identify consumers' barriers and motivations toward second-hand shopping, keywords for the literature review included "second-hand", "consumer barriers" and "consumer motivation", followed by a snowball search. To complement the literature on consumers' motivations and barriers to second-hand shopping 20 informants were interviewed, including men (n=9) and women (n=11) between the age of 21 to 79. The informants covered five groups: 1) students establishing their first home, living on public welfare, 2) adults with small kids, 3) adults with no kids, 4) adults with teenage/grown-up kids, full-time jobs, and 5) pensioners. The informants included people who have practiced second-hand shopping for decades, people who avoid second-hand shopping, and in between.

Semi-structured interviews were chosen as it allows conversations to flow freely and give the interviewee the opportunity to express any feeling toward the topic (Brinkmann & Tanggaard, 2020). For this purpose, there were neither set limitations on which second-hand markets (online and RL) should be the topic of discussion. For the data analysis, all barriers and motivations were included regardless of the frequency of them being mentioned. Pilot interviews were made to develop the interview guide (Kvale & Brinkmann, 2015), which covered three themes: second-hand products, second-hand shopping, and self-identity. Each interview lasted 40-60 minutes, was audio recorded, and transcribed to conduct the qualitative content analysis.

## Results of the literature review

Reviewing the literature resulted in a proposal for a distinction between seven themes of barriers and motivations for second-hand shopping. These themes are used to structure this chapter, and for each theme, a non-exhaustive number of examples are given as found in the literature. Some terms were directly taken from the literature (e.g., contamination (Baxter et al., 2017) and economy (Guiot & Roux, 2010)), while others were chosen by the authors (e.g., social) when it was considered useful to combine several barriers and motivations under one umbrella term where literature did not suggest such a term.

### *Contamination aspects*

Contamination can be positive or negative. For example, Baxter et al. (2017) mention concerns about hygiene as a barrier, as disgust may be evoked by the thought of pathogens. This especially concerns products worn close to the body (Edbring et al., 2016) or food-related products (Mugge et al., 2017). Fear of pests is another barrier (Edbring et al., 2016). In many cases, physical or digital marks can be considered a negative utility, as the functional value (including social-, aesthetic, and economic functions) decreases with usage. Another example is resistance to products used by an unwanted person or undesired environment (referred to as 'negative territory') is a barrier (Baxter et al., 2017). However, contamination may also be perceived as positive. E.g., if a product is previously used or owned by a celebrity (described as 'positive territory' by (Baxter et al., 2017)).

### *Sustainability aspects*

Sustainability, including ethics and ecology, is in literature only described as a motivational aspect (Edbring et al., 2016). For example, purchasing second-hand can provide a feeling of 'escaping' the mainstream consumption system or taking revenge on it, and support a less wasteful lifestyle, which is to some attractive (Guiot & Roux, 2010)

### *Economic aspects*

Economic aspects contain both motivational factors and barriers. For example, some argue the financial benefit is limited, and too little money is saved compared to the effort put into purchasing second-hand (Henseling et al., 2010). This is e.g., found for rather cheap products like hangers, where the price for a new product is already low (Mugge et al., 2017). As an example of the opposite, some feel motivated to buy second-hand because they get more for the same amount of money and are driven by bargains, or simply search for a fairer price (Guiot & Roux, 2010).

### *Social aspects*

Social barriers to second-hand shopping contain for example the perception of second-hand purchasing being unacceptable in one's social cycle (Sandes & Leandro, 2019). Social aspects can also be motivational, for example, some have a desire for uniqueness and products that cannot be found in mainstream stores. Another example is consumers who see second-hand shopping as a funny social family activity or take great pleasure in talking to strangers in second-hand markets (Guiot & Roux, 2010; Edbring et al., 2016)

*Quality aspects*

Concerns and expectations of quality also play a role. E.g., some products are considered less desirable to buy second-hand due to concerns about technological obsolescence, e.g., smartphones (Mugge et al., 2017). Yet, some consumers prefer to purchase second-hand and perceive second-hand products as being of higher quality, compared to purchasing new products of lesser quality (Edbring et al., 2016; Henseling et al., 2010).

*Shopping experience aspects*

The shopping experience is negatively affected by, for example, the lack of warranty, as consumers perceive it as risky to purchase second-hand (Mugge et al., 2017; Guiot & Roux, 2010). This can also be due to inconsistent product information, which awakens fear of dishonest information from the sellers (Akerlof, 1978; Guiot & Roux, 2010). On the other hand, 'treasure hunting' for example is found to be a motivational factor (Guiot & Roux, 2010).

*Design aspects*

Some consumers are drawn to being the first user, particularly like the smell or look of something new, or simply have not considered the alternative to purchasing new (Edbring et al., 2016). However, purchasing second-hand goods provide some consumers e.g., with nostalgic pleasure, as they are perceived as more authentic, and with history (Guiot & Roux, 2010). Moreover, some products are no longer available on the mainstream market, and thus second-hand become attractive (Edbring et al., 2016).

## Additional barriers and motivations

The analysis of 286 sortable quotes from interviews was systematically clustered with respect to existing barriers and motivations, and where that was not possible, new barriers and motivations were formulated. Through this process, seven additional barriers and five motivations were identified, which all could be sorted under the seven previously identifies themes:

*Social (barrier)*

Among a group of informants, a frequent answer to the question: *"would you call yourself a second-hand shopper?"* was, that they do in fact shop second-hand, but only very limited or specific product categories, and hence they **do not identify as second-hand shoppers**. Some explain that they find the term 'second-hand shopper' related to certain product categories, or a style/expression, which they did not identify with.

*"It is not, that I don't buy second-hand, I'm just not a second-hand shopper."* – Informant #15

*Social (motivations)*

Second-hand shopping or simply just looking through second-hand markets (RL and online) has been found to be a **recreational activity**. Informants describe how this time alone is stress-relieving and entertaining:

*"I can spend hours in second-hand shops alone! (…) It's like balm to the soul."* – Informant #14

*"I scroll Facebook Marketplace and DBA [online platform] in the afternoon like other people scroll Instagram"* – Informant #7

**Showing off own expertise** is to some a driver. Informants explain how they advertise second-hand to show others what great things you can get second-hand, and how they like 'bragging' about second-hand bargains and showing off their treasures.

*"If people compliment something I bought second-hand, a jacket, for instance, I always say: 'thanks, it was 250dkk charity shop. I want to advertise second-hand."* – Informant #13

**Charity** is also a motivation for some informants. One informant tells, how she generally finds it way too complicated to buy things second-hand but has found few exceptions: instead of renting glassware, etc. for larger parties, she buys it second-hand. After the party, she washes everything and re-donate to a charity shop. She argues that it is cheaper than renting, but also that it is important to her, that the products get donated to charity organizations, which she finds important. Others are not as specific but are motivated by the charity in general.

*"My money goes to charity. (…) That means something to me as well."* – Informant #13

### *Quality (motivation)*

To some informants the **material value** is very important, hence they seek specific materials, as these have a value beyond the design- or brand value. They become 'amateur experts' in seeing the difference between artificial and real leather, between artificial and fake fur, recognizing silk, memorizing jewelry stamps, etc.

*"I would much rather have a pair of leather boots and a fur jacket, than a Louis Vuitton handbag. Buying something in leather, silk, or fur second-hand, you pay for material value. That's worth more, in my opinion."* – Informant #2

### *Shopping experience (barriers)*

**Lack of exchange service** is to some informants a barrier, which causes them to think more thoroughly before purchasing. This is also frequently mentioned as the reason for not buying gifts second-hand. Another informant reports, that she would like the possibility to return products, which did not live up to her expectations or were broken.

*"I do so much second-hand shopping, but as my girls grow older, I buy less and less for them. They love second-hand, but when you cannot exchange things, I do it less. You end up wasting a lot of money even if the clothing is only DKK 80."* – Informant #13

Few informants mentioned **the smell of shops** as a barrier, which worsens the shopping experience and decreased their willingness to purchase second-hand. However, some said, that it had been a barrier to them, but not anymore, partly because the smell has disappeared in most places during the past years.

*"There is just something about charity shops and smell. It smells like old grandparents. It doesn't really enhance the shopping experience"* – informant #9

Many informants expressed how some types of **interior designs** can be a big disadvantage. Some expressed that they had favorite types of markets, e.g., preferred shops that were mapped out by product categories like regular shops, while others also partly enjoyed the more chaotic and mixed product categories e.g., at flea markets and flea supermarkets.

*"The second-hand shops get a little messy sometimes. It requires lots of energy to get an overview, if all the product categories are mixed up like in the flea supermarkets."* – Informant #5

Especially clothes sorted by color were mentioned by several informants as a reason for frustration, as none of them went second-hand shopping looking for something in a particular color, but rather looking for a function (e.g., jacket, or dress).

*"It is a bit weird when all the clothing is sorted by color. I never enter a second-hand shop to buy blue clothing, I look for a t-shirt for instance."* – Informant #1

Some informants point towards the **location and opening hours** of second-hand shops as a barrier. Some informants explain that they tend to 'forget' the existence of second-hand shops (both in general and specific shops), as they are not located in the pedestrian street where other shopping is usually taking place. Furthermore, opening hours different from regular shops has also been mentioned as a barrier.

*"If they were open and located so that one walked past them when shopping on the pedestrian street, one would buy more second-hand, because the need for something would occur"* – Informant #9

As second-hand shopping can be a **time-consuming** activity if seeking a very specific product, some informants see it as a barrier. Related to the product portfolio, they do not expect they can get what they want in the second-hand markets.

*"It is time-consuming, and I cannot be sure to get what I'm looking for."* – Informant #16

### *Design (motivation)*

Some explain that the wear-and-tear of second-hand products can be positive, as they feel less afraid of breaking them, thus **easing ownership**. A number of interviewees explained how they prefer to buy second-hand products, that already had some wear and tear, for situations where they preferred not to expose their pre-owned, more expensive products to situations which they could not fully control, like wine glasses for everyday use, or duvets used by guests in a summerhouse.

*"It didn't matter if they [cups] had shards. (…) To be honest, I think I like it when something looks a little worn. It makes me less afraid of breaking my belongings"* – Informant #4

*Summary of analysis*

In total the analysis adds seven barriers and five motivations to the existing literature (indicated in bold font in Table 1).

| Themes | Barriers | Motivations |
|---|---|---|
| **Contamination** | • Hygiene (Baxter et al., 2017; Edbring et al., 2016)<br>• Negative utility (Baxter et al., 2017; Mugge et al., 2017)<br>• Negative territory (Baxter et al., 2017)<br>• Pests (Edbring et al., 2016) | • Positive utility (Baxter et al., 2017)<br>• Positive territory (Baxter et al., 2017) |
| **Sustainability** | | • Distance from the system (Guiot & Roux, 2010; Edbring et al., 2016)<br>• Ethics and ecology (Guiot & Roux, 2010) |
| **Economy** | • Minimal financial benefit (Mugge et al., 2017; Henseling et al., 2010) | • Gratificate role of price (Guiot & Roux, 2010)<br>• Search for a fair price (Guiot & Roux, 2010) |
| **Social** | • Socially unacceptable (Sandes & Leandro, 2019)<br>• **Does not identify as a second-hand shopper** | • Originality (Guiot & Roux, 2010)<br>• Fun activity (Edbring et al., 2016)<br>• Social contact (Guiot & Roux, 2010)<br>• **Recreational activity**<br>• **Showing off own expertise**<br>• **Charity** |
| **Quality** | • Technological obsolescence (Mugge et al., 2017) | • Better quality/durability (Henseling et al., 2010; Edbring et al., 2016)<br>• **Material value** |
| **Shopping experience** | • Lack of warranty (Mugge et al., 2017; Guiot & Roux, 2010)<br>• Inconsistent product information (Akerlof, 1978; Guiot & Roux, 2010)<br>• **Lack of exchange service**<br>• **The smell of shops**<br>• **Interior design**<br>• **Location of shops**<br>• **Opening hours of shops**<br>• **Time-consuming** | • Treasure hunting (Guiot & Roux, 2010) |
| **Design** | • Desire for new products (Edbring et al., 2016) | • Availability (Edbring et al., 2016)<br>• Nostalgic pleasure (Guiot & Roux, 2010)<br>• **Easy ownership** |

**Table 1. Summary of consumers' motivation and barriers to second-hand shopping. The use of bold font indicates additional barriers and motivations found in this study.**

## Discussion and conclusion

Based on a qualitative content analysis of 20 interviews, this study contributes by adding five motivational factors and seven barriers to second-hand shopping (Table 1). In particular 'the shopping experience' several new barriers were identified, which suggests that this area lacks research. Due to the method of data collection, the informants were not asked about each motivation and barrier one by one, as the aim was to broadly explore the informants' experiences. Hence some barriers and motivations are only mentioned by 1-2 informants, while others had greater consent among several informants. Thus, based on this study alone, the weight and order of the motivations and barriers cannot be determined. To explore the hierarchy of barriers and motivations of second-hand consumption, the authors hence suggest a quantitative study systematically collecting the frequency of the barriers and motivations identified in Table 1.

Furthermore, analyzing the interview data suggested that certain combinations of barriers and motivations were more often mentioned by informants than other combinations (e.g., the two motivations 'positive utility' and 'easy ownership' were mentioned together, as well as the barrier 'minimal financial benefit' in combination with the barrier 'time-consuming'). This suggests that a larger dataset and further research on this topic could enlighten the archetypes of second-hand consumers, hence a combination of barriers and motivations per archetype.

**Keywords**: Circular Metal Economy; Preferable visions; Visions for 2050; Co-design research; sociotechnical visions.

**Abstract**: The UK government's target of achieving net-zero emissions by 2050 has created an urgent need for decarbonization and the transition towards a circular metal economy (CME). The production of steel and aluminium, critical components of modern industry, contribute significantly to greenhouse gas emissions and are the focus of this paper. This paper explores the barriers and enablers involved in moving towards a CME. Although recycling is an essential strategy for metal recovery, it may not suffice to achieve the UK government's net-zero objectives. The paper suggests twelve preferred visions for a CME, encompassing the entire metal value chain, co-created through collaboration with over one hundred industry and academic experts. These visions can serve as a foundation for co-design workshops for academics to investigate additional barriers and enablers within the metal sector. Within corporate management, these visions can be used to set targets and guide decision-making towards specific circular and sustainable goals. Finally, policymakers can use these visions to develop a roadmap or comprehend the implications and rebound effects of a CME transition for the UK.

## Introduction

The urgent need to decarbonise the metal ecosystem and transition towards a circular metal economy (CME) is becoming increasingly pressing, given the UK government's goal of reaching net-zero emissions by 2050 (HM Government 2021). Steel and aluminium are fundamental elements of modern industry, yet the production and use of these elements contribute significantly to greenhouse gas emissions and climate change (Izatt, 2016). Although various downstream measures throughout the value chain, such as recycling, recovery, and reuse of products and components in some industries (e.g. automotive industry), have already been widely adopted, they are insufficient to meet the net-zero targets set by the UK government (Cooper et al., 2012). Therefore, the objective of this research, conducted as part of the CircularMetal project, a UKRI-funded research centre, is to present co-created sociotechnical visions that promote the transition towards a CME in the UK across the whole metal value chain.

To achieve this objective, we gathered insights from over one hundred experts with diverse backgrounds, including governmental organisations, businesses, NGOs, policymakers, and scholars from various academic disciplines. By utilising a co-creation approach, our aim is to develop a shared understanding of a desirable future and the barriers and enablers associated with it.
Through five research phases, we co-created twelve visions that aim to guide present decision-making and actions towards a more desirable future (Manzini, 2003). These visions highlight the necessity for simultaneous action from all parts of the metal value chain to achieve the 2050 target of net-zero emissions (Kaldrack et al., 2023).

## Methodology

For the purpose of this study, we used a 'preferable future' to envision how a CME in the UK would look in 2050 (Fig 1). Preferable future is one that we strive to create and hope for. This future is based on our aspirations and ambitions, and it embodies our visions of a better world. As shown in Fig. 2, in this research the preferable future is encapsulated in the depiction of a scenario, a set of visions and a set of ‘snapshots from the future’. *Scenario* is a complex storyline that envision a desirable future, such as achieving a drastically improved metal circulation by 2050. *Visions* are used to articulate the scenario and provide brief stories detailing aspects related to specific parts of the metal value chain. They answer the question "What would the world be like if...". *Snapshots from the future* are the most specific components of a vision and can provide ‘depth’ and ‘substance’ to it. It answers the basic question: "How would the vision look in practice?". And it does so by providing practical and visual examples of the implications that a certain vision could have on our lives.

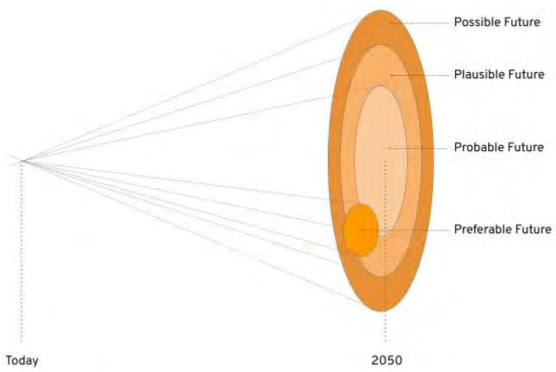

**Figure 1. Future cones (readapted from Hancock, et al., 1993).**

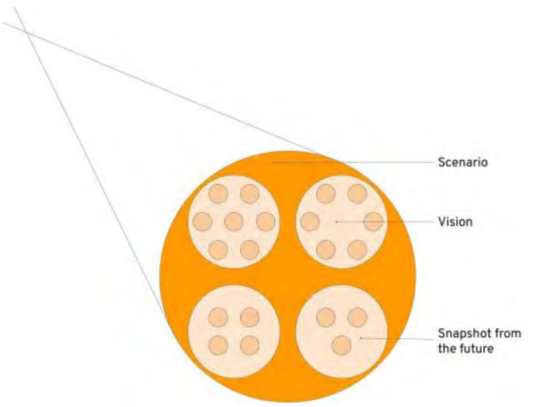

**Figure 2. Visualisation of the interrelationships between various future elements employed in our study.**

The study adopted a combination of qualitative research methods, such as semi-structured interviews, surveys, and co-design workshops, organised into five distinct phases as outlined below:

*1. Semi-structured interviews with 31 leading experts*. We carried out semi-structured interviews to gather experts' preferred visions for a Circular Metal Economy in 2050. We probed on the feasibility and implementation of their visions, with interviews lasting between 40 to 60 minutes. Our questioning encompassed the experts' future aspirations for circularity in metals, and an examination of the key enabling drivers and barriers to achieving these visions. The interviews were recorded, transcribed, and subjected to a thematic analysis to identify patterns and themes. Based on these insights, we derived eight initial visions, each illustrated through a set of "snapshots from the future" showcased in the following section.

*2. Narration and illustration of the visions.* The emerging visions were conveyed in narrative form, while snapshots from the future were depicted using a combination of visual and narrative approaches.

*3. Internal workshop with 8 academics.* The results of the previous phase were thoroughly reviewed and examined to generate novel concepts for future visions and snapshots. This led to reclustering the themes into 12 visions.

*4. Survey with 25 leading experts.* An online survey was conducted to gather feedback on the 12 generated visions in order to validate and refine them.

*5. Co-design workshop with 29 experts.* A 3-hour co-design session was carried out to further review the generated visions and to identify, for each of them, implementation barriers and enablers (taking into account political, economic, social, technological and legislative aspects).

The selection of experts for this research was based on their specialised or correlated knowledge and extensive experience in the fields of aluminium, steel, and sustainability. Additionally, these experts were chosen to represent a wide range of stakeholders, thereby ensuring comprehensive coverage of the entire metal value chain.

**Figure 3. Preferred scenario for the circular metal economy in 2050, encompassing twelve different visions.**

## Results

In this section of the paper, we present the preferred scenario that has been developed during phases 1, 2, 3 and 4 of our research. As shown in Fig. 3, the scenario is structured around 12 visions, including: 1. Net Zero Emission Metal Production; 2. Circular Alloys; 3. Distributed Metal Manufacturing; 4. End-To-End Supply Chain; 5. Metal as a service; 6. Metal Life Cycle Data; 7. Full Metal Packaging; 8. Stop Recycling Start Repairing; 9. Repair-It-Yourself (RIY); 10. The Logic of Sufficiency; 11. Reusing, Remanufacturing, and Repurposing; and 12. Better Metal Recovery, Sorting, Upcycling and Recycling. The scenario has been crafted to present a compelling storyline for the future that is desirable for all stakeholders. To depict the envisioned future in 2050, realistic images were generated using Photoshop and other tools for each 'Snapshot from the future.' The preferred scenario is illustrated in Fig. 4, which comprises a compilation of diverse images. The full set of visions can be found in Franconi et al., 2022.

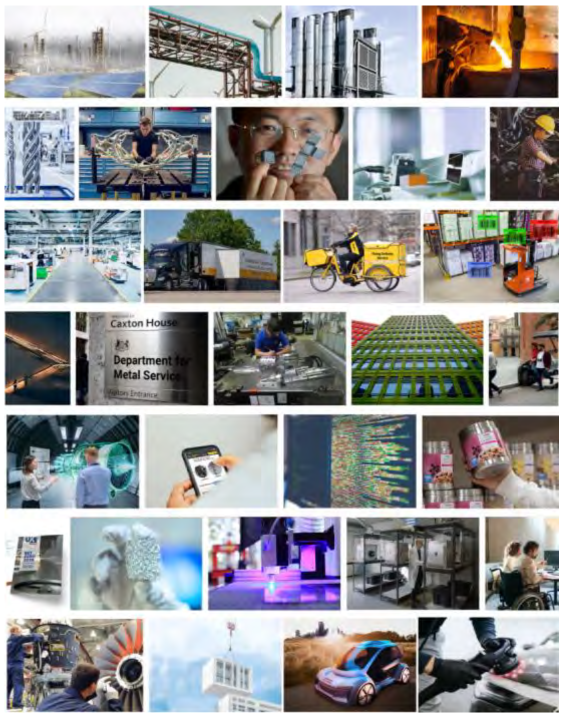

**Figure 4. An overview of the images created to depict each individual 'Snapshot from the future'.**

*Preferable scenario*
"It is the year 2050, and the UK has achieved complete circularity in the domain of metals, a remarkable achievement of human ingenuity and a virtuous pursuit towards a better world. This victory was hard-won, but thanks to breakthroughs in areas like renewable energy, energy storage, and process efficiency, we're now able to produce metal with zero emissions (1). Efforts to rationalise alloy grades and usage have resulted in the creation of novel "circular alloys" that enable a more effective closed-loop system to be adopted (2). At the end of their life, all kinds of metals are now separated and classified according to their unique and remarkable characteristics, safeguarding their distinctive qualities to be reused again and again (12).

The advent of new manufacturing technologies has led to the rise of distributed factories, promoting localised production, mitigating transportation costs, and increasing suppleness in supply chains, which fostered the growth of self-sufficient and adaptable economies. This has increased job opportunities, enhanced knowledge sharing and networking, and established a new collaborative economy, reducing regional disparities in wealth and economic development (3). Intelligent assets have been implemented, leading to complete integration and automation of the end-to-end supply chain and enabling real-time monitoring and execution of all supply chain processes (4). The UK government's open metal data infrastructure makes this feasible by providing data to all supply chain players. Due to efficient resource management, advanced metal recovery, sorting, upcycling, and recycling processes have been implemented (6).
The emergence of servitization in the metal industry has positioned the UK as a global leader. The shift towards valuing product use over mere possession has enabled companies to enhance product quality, curtail material consumption, and augment resource circularity (5 & 7). The transformation of companies into agents of good is demonstrated not only by their ability to offer services, but also by their commitment to creating products that can be utilised in multiple life cycles. This shift towards the reuse and remanufacturing industries marks a turning point in the manufacturing industry's ethos (11).

The development and consolidation of the repair industry in recent decades have given rise to new forms of work and an economy based on the repair itself (8). Repair has been embraced as a way of life for many individuals as well (9). These profound transformations in society have created long-term economic stability, shaping novel moral imperatives and ethical norms on sufficiency that unite the overall community (10)."

## *Stop Recycling, Start Repairing - Barriers and Enablers*
In Phase 5 of our study, we evaluated the obstacles and opportunities associated with each vision. Due to space limitations, this paper focuses only on the (8) "Stop Recycling, Start Repairing" vision. This vision suggests a shift to a repair-based economy utilising advanced technologies and Metal Health Services for metal maintenance and self-healing capabilities, resulting in extended product lifetimes. With a multi-dimensional lens, encompassing social, technological, ecological, economic, and political aspects, our analysis investigates the most significant barriers and enablers that the industry is facing.

*Social lens*: The lack of skilled maintenance and repair experts is a significant barrier to the realisation of a vision for sustainable and efficient industrial practices. This barrier arises due to a shortage of qualified personnel capable of carrying out planned maintenance and specialised repair activities. This lack of skilled personnel leads to a higher incidence of equipment breakdowns, which can result in lost productivity, increased downtime, and higher maintenance costs. To overcome this barrier, vocational and engineering colleges should include repair education as an essential part of their curriculum. This approach would enable students to acquire the skills and knowledge needed to become competent maintenance and repair professionals. Moreover, knowledge-driven organisations should be supported and funded to develop repair knowledge in specific sectors, such as electrical repair, to encourage the growth of specialised expertise.

*Technological lens*: The development of smart metals (e.g., self-healing) and novel repair methods represent a promising vision for many industries. However, ensuring safe and effective commercialisation is challenging. One significant barrier is the need for safety assurance, requiring rigorous testing of smart materials to avoid risks to human health and the environment before entering the market. Safety is critical for smart materials and repair methods and evaluating and mitigating potential risks before commercialisation is necessary to unlock their benefits. Nonetheless, opportunities and enablers exist to facilitate the vision's realisation. Controlled evaluations of advanced materials and repair equipment's safety and performance based on scientific evidence are necessary to guarantee long-term quality and safety. These evaluations can identify the effectiveness and safety of smart materials and repair methods while fostering trust in their adoption.

*Ecological lens*: Smart metals show great promise for revolutionising various industries, from transportation to medicine. However, creating new hazardous waste from their use is a major concern, particularly for self-repair metals. It is unclear whether these metals can be recycled in the same way as conventional metals, further exacerbating the issue. To fully realise the potential of smart metals, it is important to research and develop sustainable recycling methods to avoid producing new waste streams or hazardous waste. Addressing these concerns will reduce the environmental impact and associated risks of smart metals, promoting their long-term viability and success in industries.

*Economic lens*: A key obstacle to a full transition to a CME is the insufficient evidence on the cost-effectiveness and environmental characteristics of new materials and repair techniques to support a repair-based economy. Without this data, the adoption of repair-based practices may be hindered. Conducting economic and environmental research on repair is essential to establish the benefits of this approach. Promoting and supporting such studies can provide insights into the economic and environmental advantages of repair-based practices, enabling informed decisions on the transition to a CE. Overcoming the barrier of inadequate evidence is crucial to realise the vision of a CME.

*Political lens*: Repair activities may be restricted or prohibited by laws, regulations or contractual agreements, which hinder the ability to extend the use of products. For example, warranties may limit the use of third-party repair services, restricting consumer choice, which may prevent the prolonging of the lifespan of products. To overcome these barriers, a framework is required to support repair and reuse. A contractual/legal framework that promotes repair, longer product lifespans, and multiple owners/users over a period of time is crucial for enabling a CME. This framework should establish clear rules and guidelines that support repair and reuse, facilitate access to repair services and spare parts, and promote the sharing of products between multiple users. It should also incentivise producers to design products that are easy to repair, upgrade and disassemble at end-of-life.

## Discussion and conclusions

The transition towards a CME is a multifaceted and complex process. This paper's particular focus on Vision 8 "Stop Recycling, Start Repairing" has demonstrated how achieving its objectives demands a range of interventions that are intertwined across different sociotechnical domains. This becomes even more clear when we analyse all the visions in a polarity diagram that juxtaposes behavioural and social dimensions with technological dimensions, highlighting the interplay between these two transformations as illustrated in Fig. 5. While technological advancements are crucial in driving this transformation, it is equally important to consider the social dimensions that underlie the system, particularly during the usage phases. The majority of the visions outlined in the study emphasised the importance of life extension and the adoption of circular metal solutions that are low-resource intensive and have a high degree of regenerative potential. Circular business models, sustainable supply chain management, and circular design strategies all play vital roles in this transformation.

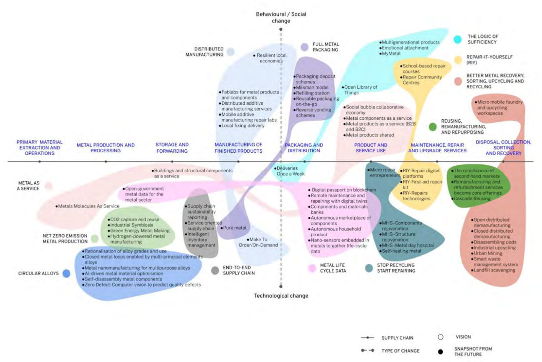

**Figure 5. Circular metal economy polarity diagram with all visions and Snapshots from the Future. The vertical axis represents behavioural/social change and technological change, while the horizontal axis shows all phases of the metal chain. An enlarged version of the image is provided in the appendix 1.**

Based on the barriers identified by experts, it is clear that despite the current emphasis on metal production and recycling, driven by established infrastructure and economics, government policies, and scholarly literature, a fundamental shift in societal behaviour is essential to achieve the full potential of a CME. In fact, the recurring barriers noted by experts throughout the visions emphasise the significance of orienting employees, users, communities, and businesses towards a circular mindset. Although legislative incentives may prove effective in catalysing this shift, it is essential to recognise that the creation of a CME is contingent on coordinated investments in both the scientific and physical infrastructure needed for the transition. For example, a possible coordinate investment may include the creation of novel educational frameworks aimed at facilitating stakeholder understanding of standardised circular-related data, as well as the adoption of technological infrastructure to enable effective tracking of products across the entire supply chain.

The findings of our study underscore the crucial role of collaborative efforts by all stakeholders in overcoming the barriers to transitioning to a CME. The success of this transition requires addressing multiple factors, including social, economic, technological, and environmental considerations that are integral to the system. A holistic approach that considers the entire lifecycle of materials is necessary for realising the benefits of a CME. In particular, the steel and aluminium sectors can play a pivotal role in this transition by extending the product lifecycle and adopting new business models that go beyond traditional recycling methods. This shift in mindset would enable a more sustainable use of materials, while also opening up new opportunities for innovative and profitable business models.

Sociotechnical visions of preferable futures are influential in shaping present decisions and commitments. In this paper, we have identified twelve distinct visions in the metal sector that provide a comprehensive outlook on the opportunities for transitioning towards a circular economy. Subsequently, we have conducted an analysis of the significant barriers that need to be addressed to achieve these visions. While we acknowledge that these visions are only a few of many plausible futures, using them as a target for our efforts can guide us in shaping immediate short-term actions. Overall, this research provides valuable insights into the sociotechnical implications of transitioning to a circular economy in the metal sector. It emphasises the importance of considering various preferable futures to guide present decisions and actions. Future research may focus on initiatives similar to this one, generating preferable visions and then determining the barriers and enablers to achieving useful results. Moreover, using these visions as a starting point, it would be helpful to make a road map to help all stakeholders set their goals and focus on clear, well-defined objectives.

## Acknowledgments

The research project received financial backing from the UKRI National Interdisciplinary Circular Economy Research programme (NICER). The authors would like to express their sincere appreciation to the experts who took part in the study and generously shared their time and expertise.

**Keywords**: Reuse; Cascading; Relink; Circular Economy; Design for X.

**Abstract**: This study focuses on the role of the reuse recovery approach and its strategies in the circular economy through a product design lens. While the circular economy has been widely discussed, not all recovery strategies have been thoroughly investigated and understood alike. This research differentiates between reuse and other recovery strategies and defines three distinct opportunities under the 'reuse umbrella' – reuse, cascade and relink. For each opportunity, possible sub-opportunities are identified and elaborated. Through a multiple case study analysis, the sub-opportunities are elaborated with a "Design for X" approach into eight different strategies of reuse, including design for direct reuse, reconfiguration, material cascading, repurposing, component reuse, creative reuse, material reclamation and adaptive reuse. The research emphasises that the appropriateness of a reuse strategy depends on various aspects such as the context, users, industries, and material flows. Also, this study stresses the importance of reuse in promoting circular product development and consumption, providing valuable implications for businesses and designers.

## Introduction

The concepts of reuse, cascading, recirculation, regeneration, reprocessing, repurposing, and renovation have deep roots in human history and have been a fundamental aspect of resource management for centuries. These practices have traditionally occurred on a local, informal level within households or communities, where resources were shared and conserved for generations among members (Sirkin et al., 1994). However, with the advent of wealth, particularly in developed economies, these traditional methods of resource management have been replaced by less sustainable practices (Cooper, 1994). But in recent years, there has been a renewed interest in these activities as they are seen as a viable solution to the environmental and societal issues caused by modern consumption practices (Wieser et al., 2018). This type of economy, based on circular economy (CE) and sufficiency, can foster a more efficient and sustainable society (Bocken et al., 2016). The aim of this research paper is to broaden the understanding of the concept of reuse from a design perspective and to present a novel approach to defining design strategies that maximise value reuse. Through the lens of the "Design for X" approach, we analyse the three strategies of reuse, cascading, and relinking to identify key strategies, components, and factors that contribute to successful initiatives (Sirkin et al., 1994). Our approach integrates the concepts of reuse with cascading and relinking to hierarchize strategies and emphasises the importance of reuse in the design process. By examining both implemented and conceptual case studies, we offer insights into potential future developments in this field and provide valuable information for designers and stakeholders interested in implementing reuse, cascading, and relinking strategies.

## Materials and Methods

This study employed the methodology proposed by Yin (2011) to identify and analyse individual cases to gain comprehensive insights and understanding opportunities in design for reuse.

1. *Research questions*: How can designers approach the concept of designing for reuse, and what are the different design strategies that can be employed to support this objective?
2. *Research propositions*: A classification of the design for reuse strategies employed by designers, in terms of their approach, characteristics and applicability (in terms of different products, processes, and industries).
3. *Research unit(s) of analysis*: The various strategies that can be differentiated to formulate overarching approaches that can be adopted and replicated by designers, focusing on technical material cycles only.
4. *Logic linking the data to the propositions*: To understand reuse, a literature review was conducted (Stage 1), followed by case studies that were pattern-matched to definitions of reuse (Stage 2), and finally, each reuse strategy was described as a "design for X" strategy (Stage 3).
5. *Criteria for interpreting the findings*: The criteria used for this research are the following: (1) Aim of the DfX strategy; (2) Type (product, component, material), origin of the value and industries; (3) Intended reuse and functionality (same or different purpose); (4) Ownership of the product and responsibility for its use and maintenance during the usage; (5) Increase, no change, or a decrease in value (market value) compared to the previous life cycle; and (6) Reprocessing method for enabling reuse of the value and the entities accountable for performing it.

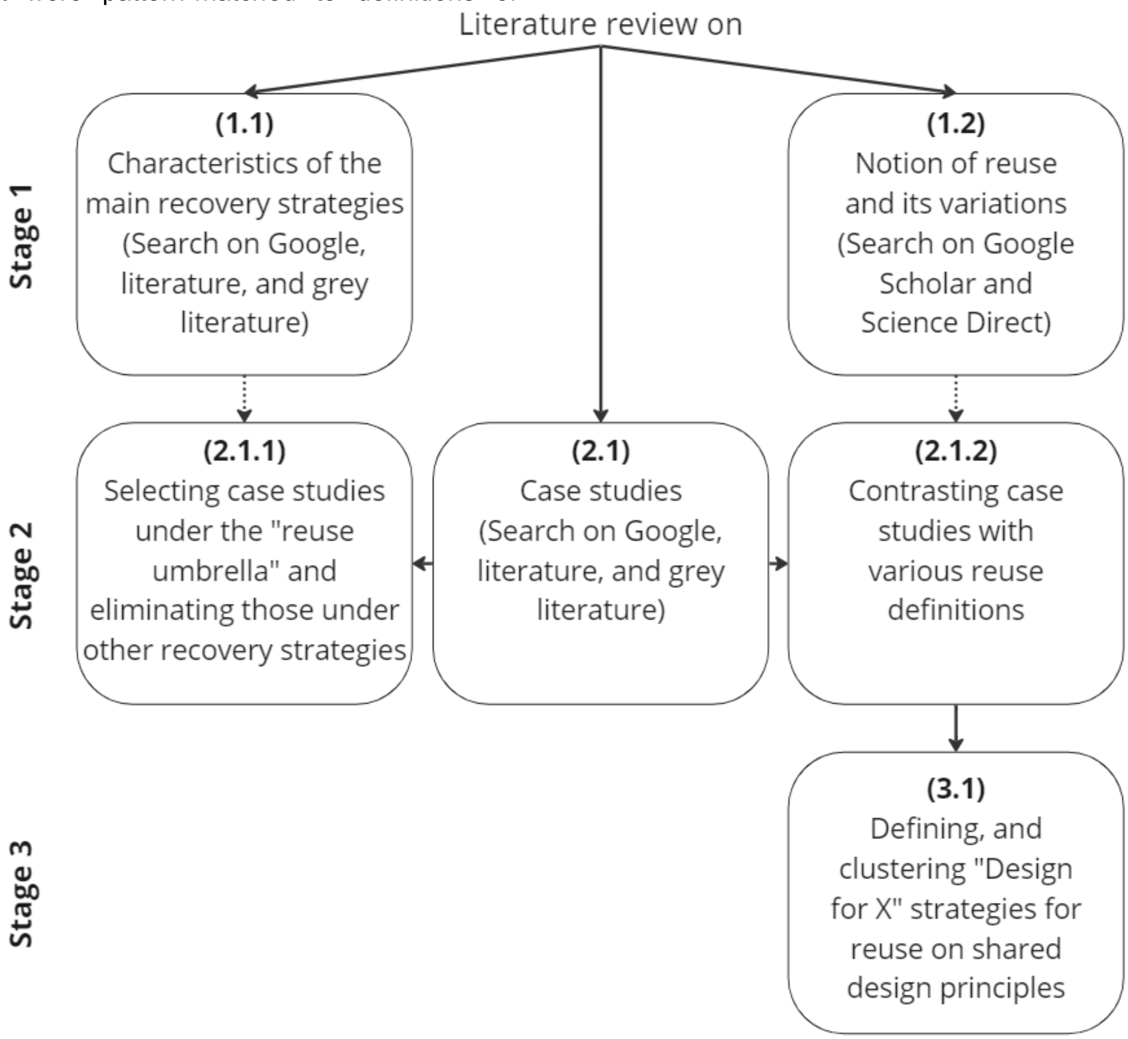

**Figure 1. Stages of the multiple-case study analysis.**

## Results

*Stage 1*

In the initial stage, we conducted a comprehensive literature review on reuse in order to gain a holistic understanding of the subject. The literature reveals a common tendency to confuse the idea of reuse with alternative circular strategies, such as refurbishing or remanufacturing (Linton et al., 2005). This can result in a limited understanding of the potential impact of reuse, as well as the importance of prioritising the inner loop and retaining the highest value possible from a product (Wieser et al., 2018). The lack of clear differentiation between recovery strategies may impede progress towards more sufficiency and a CE (Gharfalkar et al., 2016; Reike et al., 2018). In order to fully leverage the benefits of reuse, it is crucial to distinguish it from other circular strategies and to highlight its unique characteristics and value. While there are a few attempts in the literature to define and categorise different approaches to reuse (Franconi et al., 2022), these efforts have been limited in scope and generally lack a comprehensive framework for analysis. The majority of authors who discuss reuse at a general level often rely on the definition provided by the EU (2008, Article 4(13)), which defines reuse as the reuse of a product "as is". However, some researchers who conduct a more in-depth analysis of the reuse phenomenon view it more broadly, encompassing components and materials (Keoleian et al., 1993; Beamon, 1999; Bavan et al., 2013; Chiu et al., 2011; ). Table 1 combines the two approaches under the Reuse ‘umbrella’ and presents a comparative analysis of the main recovery strategies based on the following criteria: quality, aesthetics, intended reuse purpose, type of value (product, component, or material), design aim, reprocessing, and product market value.

| | MAIN RECOVERY STRATEGIES | | | | | |
|---|---|---|---|---|---|---|
| CHARACTERISTICS | Long-lasting | Reuse umbrella | | Refurbish | Remanufacture | Recycle |
| Quality | Original | "As is" and working condition | Reused it anyway possible | Like new/or almost new | Like new or better than new | Usually lower than the original |
| Aesthetics | Original | Original | High/low | Original | Original | Low |
| Intended reuse purpose | None | Same | Slightly same or different | Same | Same | Different |
| Type of value | Products | Products | Products, components, materials | Products, components | Products, components | Materials |
| Design aim | Longevity | Reuse | Maxime reuse | Restoration | Renovation | Maxime reuse |
| Reprocessing | Upgrading (expert or DIY) | Cleaning (expert or DIY) | Upgrading, Adaptation Retrofitting (expert or DIY) | Cleaning/Repair (expert repairing) | Disassembly/ Repair (expert repairing) | Recycling (expert) |
| Product market value | High | High | Low | High | High | Low |

**Table 1. Comparison of recovery strategies characteristics. Note that the table is based on a broad context, and characteristics may vary according to the specific case and context. An enlarged version of the image is provided in the appendix 1.**

Very few attempts have been made to pinpoint what exactly constitutes reuse. Etienne (2015) identified 22 distinct overarching approaches for reusing activities. These approaches range from the use of formal reuse systems and the implementation of product evaluation and repair facilities to more informal and community-based approaches such as the sharing economy and water reuse. Aguirre, (2010) focused more on the design aspect of repurposing. She suggests three types of repurposing initiatives: (1) Planned repurposing, (2) Coached repurposing/suggestions, and (3) Open-ended repurposing. In their study, Sihvonen et al. (2015) proposed a comprehensive classification of reuse strategies, which was primarily categorised into six groups: (1) Resale or direct reuse, (2) Repurpose, (3) Repair, (4) Refurbish, (5) Remanufacture, and (6) Resynthesize. The authors sought to provide a systematic framework for evaluating and implementing various forms of ReX for aggregating end-of-life strategies. Sirkin and ten Houten (1994) directed their attention towards the economic and practical dimensions of reuse. They were the first to introduce the notion of cascading and relinking as a means of distinguishing whether the product gains or loses worth during the process of reuse. Their work enabled the categorization of ‘reuse umbrella’ into three distinct types, namely Reuse (value remains unchanged), relinking (value increases), and cascading (value decreases). These categorisations were subsequently used to group and analyse various reuse concepts from existing literature. The selection and organisation of terms with equivalent meanings are summarised in Table 2.

| | Categorisation of reuse based on value | Terminology of reuse selected for this study | Alternative terminology used in literature |
|---|---|---|---|
| Reuse umbrella | Reuse (value remain unchanged) | Direct Reuse | Resale or direct reuse (Sihvonen et al.); Reuse (Keoleian, et al.); Conventional Reuse, Reusable, and Second-Hand products (Etienne); Reuse (Wilts et al., 2018) |
| | | Reconfiguration | Reconfiguration (Sibanda et al.); Reusing structural components for multiple service cycles (Brütting et al.) |
| | Cascading (value decrease) | Repurposing | Planned repurposing and coached repurposing/suggestions (Aguirre, 2010); |
| | | Component Reuse | Reuse (Keoleian, et al.). Salvage (Etienne), Upgrading (Wilts et al., 2018). |
| | | Material cascading | Material cascading (Sirkin et al.), Reclamation (Etienne). |
| | | Creative reuse | Resynthesize (Sihvonen et al.); Open-ended repurposing (Aguirre, 2010); Creative Reuse (Etienne); Individual Upcycling (Sung et al); Individual upcycling (Sung et al.) |
| | Relinking (value increase) | Material Reclamation | Reformulation (Keoleian, et al.); Deconstruction, Reclamation (Etienne) |
| | | Adaptive Reuse | Repurpose (Sihvonen et al.); Adaptive Reuse (Etienne) |

**Table 2. Taxonomy, semantics, and clustering of terms based on literature analysis. An enlarged version of the image is provided in the appendix 2.**

### *Stage 2*

In the second phase of our study, we conducted a case study investigation using various research engines: Google, Google Scholar, JSTOR and ScienceDirect. The resultant data was compared against Table 1 as a first step. If a particular case study fell under the 'Reuse umbrella' category, it was further categorised in accordance with Table 2. Following this selection process, we have identified a cohort of 40 case studies.

### *Stage 3*

In the final phase of our study, we used the Design for X (DfX) approach to articulate all the strategies falling under the umbrella of reuse. To this end, we first created a generic description of the case studies, which were organised according to different categorizations. DfX is a systematic approach that seeks to optimise the design of products or processes by considering various factors or "X's." In our study, we used DfX to explore how different reuse strategies can be applied in various contexts. Specifically, we employed DfX to generalise and articulate the different reuse strategies based on the definitions and case studies that we identified. This involved analysing each strategy in terms of how it could be optimised for different factors or X's, such as repairing components or incorporating modularity. Furthermore, we applied five distinct criteria, as detailed in our methodology, to fully articulate each reuse strategy.

Design for Reuse (DfR)

This strategy focuses on designing products that can be reused "as is". There are two strategies that can be used within DfR that are:

1. Design for Direct Reuse (DfDR)

DfDR aims to create products that can be easily and directly reused "as is". It comprises two groups of products: (1) reusable containers, packaging, medical or industrial equipment, and (2) second-hand products such as clothing and vehicles. In group (1), designers focus on creating aesthetically simple products with durable, easy-to-clean, and high-quality materials that are safe for reuse. Products in this group are typically borrowed, rented or require a small deposit that is refunded upon purchase of the next product (Fig. 2). Group (2) includes high-quality, long-lasting products that boast extended service lifetimes but are not necessarily designed with reusability as a goal (Fig. 3). Users in this group exchange products with one another, by themselves or through intermediaries (e.g. resale platforms). Both groups consider reprocessing as cleaning for immediate reuse.

**Figure 2. Refill water dispenser jar. © Pixful**
**Figure 3. Worn Wear program. © Patagonia.**

2. Design for Reconfiguration (DfRF)

DfRF aims to design products with modular, adaptable, and reconfigurable components that can be easily disassembled and reassembled to create new products or upgrade existing ones. This strategy incorporates modular design, universal connections, snap-fit mechanisms, reconfiguration equipment, and durable materials, as well as instructions for disassembly and reassembly, to create adaptable and versatile products. DfRF products may require extensive reprocessing to be able to be reused again and adapted to a new function. Examples are scaffolding, stage structures, furniture with specialised splicing (such as Comma by Vitra), or specialised materials reconfigured with reconfiguration equipment such as Transitory Yarn.

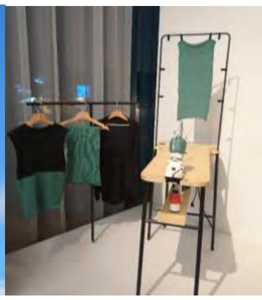

**Figure 4. Scaffolding. © Pxfuel**
**Figure 5. Transitory Yarn. © Alexandra Fruhstorfer.**

DESIGN FOR CASCADING (DfC)
DfC is the practice of designing products that are able to increase value after reuse. DfX strategies include:

1. Design for Material Cascading (DfMC)

DfMC aims at facilitating the reuse of production waste, as well as post-consumer waste materials composed of multiple components that are difficult to recycle. These materials are often reused as filling or support materials for other products, as traditional recycling methods are typically not feasible. When products or materials are reused under this strategy, they typically undergo a change in function and a significant decrease in value, with significant or moderate reprocessing required for reuse (e.g. non-recycling mechanical processes like shredding or pressing). Examples are carpet padding, textiles as reinforcements of building materials, temperature insulation materials and padding and stuffing materials.

**Figure 6. Carpet padding. © Flooring Clarity.**
**Figure 7. Insulation made of mineral wool, glass, and glass slabs. © Knauf Insulation.**

2. Design for Repurposing (DfRP)

DfRP aims to enable the efficient reuse of resources for subsequent purposes. It focuses on creating value by enabling functional changes in each step of the reuse process, while typically resulting in similar or lower market value compared to the previous life cycle. Reprocessing is minimal or not required, with ownership remaining with the user who is responsible for its use and maintenance. Examples are mainly packaging as shown in Fig. 8 and 9.

**Figure 8. Nutella Simpson Glass Tumblers. © The Hawkins Treasures.**
**Figure 9. HangerPak. © Steve Haslip.**

3. Design for Component Reuse (DfCR)

Technically, DfCR aspires to create components that can be simply disassembled and reused "as is" in other products when the entire product cannot be resold, repaired, or recycled. However, currently, this strategy is primarily utilised for goods that were not initially designed with DfCR principles in mind. DfCR is particularly applicable to products that are susceptible to wear, obsolescence, or damage (such as cars involved in accidents). Designers should consider end-of-life scenarios, use modular design and standardisation of components, and collaborate with recovery facilities to facilitate salvaging reusable parts. Usually, reprocessing requires much manual labour such as disassembling and cleaning components before reusing them in a different product. The reuse of the different components can require creative solutions like Fig.10. Other examples include cars (Fig. 11), computers and workwear components.

**Figure 10. Recraft line. © Patagonia.**
**Figure 11. Reusable vehicle parts. © Alessio Franconi.**

4. Design for Creative Reuse (DfCR)

DfCR aims to create new products from dismissed materials or products using craft, manufacturing techniques (such as 3D printing), and artistic approaches, resulting in products with unique aesthetic qualities that extend the lifespan of the original materials or products and differ substantially from the initial lifecycle. DfCR involves two sub-strategies:

Design for Individual Upcycling (DfIU) and Design for Professional Creative Reuse (DfPCR), which use discarded products, components, and materials to create new products with different market values. The process of DfCR involves a range of activities, including material reworking, heating, and the incorporation of different components and products. DfCR falls under both DfC and DfRL because, depending on who employs this strategy, i.e., a professional or a DIY enthusiast, the reused product might either gain or lose value. Diverse examples of DfIU can range from small, disposable objects to household furniture, as depicted in Figures 12 and 13. Similarly, Figure 14 and 15 illustrate the wide applicability of DfPCR.

**Figure 12. Nutella jars repurposed as vases: a DfIU case. © Nutella.com**
**Figure 13. Wine bottles repurposed as tumblers: a DfIU case. © Wasabottle on Etsy.**

DESIGN FOR RELINKING (DfRL)
DfRL is the process of designing resources in a manner that enables their reuse and increases their value in subsequent cycles. DfX strategies within the DfRL include:

1. Design for Creative Reuse (DfCR)

As previously described.

**Figure 14. Cubicle 2: a DfPCR case. © Formafantasma**
**Figure 15. 3D printed Vases Collection: a DfPCR case. © Libero Rutilo.**

2. Design for Material Reclamation (DfMR)

DfMR aims to recover and reuse waste materials without recycling and uses them "as-is" to build new goods. DfMR involves identifying sources of abundant waste materials (non-recyclable or with high economic value potential), implementing a scalable solution for those sources, and designing tailor-made solutions to reprocess and reuse these materials. The goal is to generate products that have a higher value and a different purpose than the original product. Figures 16 and 17 illustrate a few applications of this strategy.

**Figure 16. Messenger bag. © Freitag**
**Figure 17. Small Post Bag. © Elvis & Kresse.**

3. Design for Adaptive Reuse (DfAR)

DfAR aims to maximise conservation and minimum transformation characteristic of a product by retrofitting or updating with adaptable components. It focuses on creating value by enabling alternative features that the product did not initially have and in doing so prolongs the life of the product. To achieve this, designers focus on creating retrofitting products that are modular and flexible, allowing them to be easily adapted, assembled and integrated to existing products. Figures 18 and 19 illustrate a few applications of this strategy.

**Figure 18. Jar Tops. © Jorre van Ast.**
**Figure 19. Nutella Clock. © Alessi.**

## Discussions and conclusions

This paper aims to provide clarity on the implementation of design strategies for resource reuse by answering the question, "How can designers approach the concept of designing for reuse, and what are the different design strategies that can be employed to support this objective?" A classification system based on three main approaches - design for reuse, cascading, and uplinking - is used to define eight sub-strategies that provide a comprehensive understanding of reuse design opportunities. Effective implementation of these strategies can have a substantial impact on the savings of material, labour, energy, and capital required for the product, and externalities such as greenhouse gas emissions, water usage, and toxicity. However, successful implementation is contingent upon a variety of factors, including context, users, industries, and material flows. To maximise adoption of reuse strategies, designers need to tailor their designs according to these factors. Future research directions include proving the quantitative economic and environmental benefits of implementing the different strategies for businesses, analysing the different design strategies in depth, and exploring the impact of the narrow definition of reuse used in official reports by the UK and EU governments.

**Keywords**: Circular economy; Teaching; Conceptual metaphor theory; Nonlinear metaphor.

**Abstract**:
The idea of a circular economy promises radically different outcomes compared to the current, linear economy. To explore new lines of enquiry to achieve these different outcomes, metaphors can be used to allow a learner to think about a circular economy differently compared to the current economy. Conceptual metaphors are especially powerful for this purpose since they influence most abstract patterns of thought, and they have systemic properties. Therefore, this research describes an intrinsic case study about the engagement of a group of students with the metaphor of a forest during a two-day postgraduate-level course. This research addresses the question: "*to what extent does the forest metaphor allow students to rethink the relationship between businesses in a circular economy?*" Through this intrinsic case study, the insights, experiences, and perspectives of the students are analysed, after they have interacted with the metaphor of a forest.

## Introduction

The "circular economy" is an antonym for the linear economy, referring to the conventional economy which is characterised by extraction and degeneration. The circular economy promises radically different outcomes (Bocken et al., 2016; Murray et al, 2017; Geissdoerfer et al., 2017; Temesgen et al., 2021). However, some reductionist habits of thought from the linear economy, have influenced circular economy thinking (Fromberg et al., 2022; Murray et al., 2017).

Reductionist metaphors, such as the machine metaphor, tend to make sense of the economy as an entity that is removed and protected from society and the environment (Mutari, 2018). This causes the focus to be on tangible and measurable factors (such as products, emissions, and materials) instead of more social or dimensions, such as wider systemic change, which is more challenging to quantify.

To explore that an alternative conceptualisation may look like, this paper will explore what happens when postgraduate students engage with holistic metaphors with nonlinear qualities.

A nonlinear metaphor that is receiving attention within the context of a circular economy is the forest metaphor. Therefore, in this case study, the "source domain" (meaning the domain where insights are derived from) is the forest metaphor. The "target domain", which is an abstract phenomenon that one tries to make sense of, is the idea of a circular economy.

Using the forest metaphor to make sense of a circular economy has the potential to provide more nuance compared to the currently dominant competitive metaphors, such as the sports metaphor and the war metaphor (Fromberg, 2022). Expected insights that may be derived from this source domain will be around the symbiotic relationships, the interdependency between different entities in the forest and the communication that happens through the mycelium networks. All these features exist in parallel to the competition for potentially scarce resources such as nutrients and sunlight.

This paper outlines the results of a case study where students explored relationships between businesses in a circular economy through the forest metaphor. It addresses the research question: "*to what extent does the forest metaphor allow students to rethink the relationship between businesses in a circular economy?*" The paper describes the case of a two-day, workshop-style course on systems thinking, as part of the Postgraduate Diploma in Sustainable Business at the University of Cambridge Institute for Sustainability Leadership. During this course, 36 students actively engaged with the forest metaphor to understand relationships between businesses within a circular economy. The students signed up for the study, the participants, completed an experiential learning worksheet and a survey before the course started and completed a survey after the course ended.

## Background

Although metaphors are often seen in literature as individual linguistic expressions, or as the decoration of language, a more profound interpretation based on cognitive science reveals that metaphors are key to the conceptualisation of abstract ideas. Around 98% of an individual's reasoning is unconscious, requires emotion and uses the "logic" of conceptual metaphors (Lakoff, 2010). Most individuals are unaware of the metaphors that govern their thoughts and the extent to which those metaphors can influence the product of those thoughts (Lakoff. 2010). Engaging with new metaphors may allow individuals to come up with novel ideas or value already-existing ideas differently (Saffer, 2005) or explore new lines of enquiry (Strike & Posner, 1982).

Current mainstream circular economy discourse uses mostly sports and war metaphors to understand the nature of the relationships between businesses in a circular economy (Fromberg et al., 2022). However, this creates a clear tension with at least principle 8 of a regenerative economy as described by Fath et al., 2019:

1) Maintain robust, cross-scale circulation of critical flows including energy, information, resources, and money.
2) Regenerative re-investment.
3) Maintain reliable inputs & (4) healthy outputs.
5) Maintain a healthy balance and integration of small, medium, and large organisations.
6) Maintain a healthy balance of resilience and efficiency.
7) Maintain sufficient diversity.
8) Promote mutually beneficial relationships and common-cause values.
9) Promote constructive activity and limit overly extractive and speculative processes.
10) Promote effective, adaptive, collective learning.

The forest metaphor could have potential to provide insights beyond the promotion of mutually beneficial relationship and common-cause values. However, the designed learning experience of this case study will focus on conceptual development related to principle 8 in specific.

The two-day course was aimed at the development and accommodation of the conceptualisation that follows the logic of the forest metaphor. To ensure that a new conception is accommodated by the learner, the following conditions are to be met (Strike & Posner, 1982):

- There must be dissatisfaction with existing conceptions.
- A new conception must be intelligible.
- A new conception must appear initially plausible.
- A new conception should be fruitful.

This research will evaluate these conditions in the context of the forest metaphor in circular economy learning.

## Methodology

A qualitative methodology is most appropriate for exploring complex issues (Creswell & Poth, 2016) such as the interaction with conceptual metaphors by students. More specifically, the research is conducted through the methodology of an intrinsic case study. Through an intrinsic case study, an unusual or unique situation is presented (Stake, 1995). The case study in question will be the engagement with the forest metaphor during a two-day Sustainability Leadership Laboratory on *Systems Thinking*, organised by the University of Cambridge Institute for Sustainability.

This course took place on 27 and 28 February 2023 in Cambridge, United Kingdom and is part of the Postgraduate Diploma in Sustainable Business (a part-time, level 7 course). The course is not compulsory. As such, all students self-selected for participation in this course.

On the first morning of the course, lectures were presented on systems thinking and systemic problems in the context of the economy, and a reflection on the difference between systemic transitions and transformations was provided. The afternoon programme started with a lecture about metaphors and an elaboration of the learning design of the 2.5-hour workshop that followed. This 2.5-hour workshop allowed the students to engage actively with conceptualisation of a forest for a circular economy and this is the scope of this research. A second day of systems thinking content that followed this workshop is considered out of scope for this research.

### *Participant selection*
All students on the course have been invited to join this study. The course requirements are a minimum of 3 years of relevant work experience; however, most students will be mid-to-senior managers from a variety of sectors, industries, and geographies. Of the 36 students joining the course, 30 signed up to be participants in this study and filled in the consent form. Eventually, 27 participants filled in the first survey and completed the two days of the course. Of these 27 participants, 20 also completed the post-workshop survey.

### *Data collection*
The study draws from three points of data: two surveys and the pre-course preparation worksheet. The first survey was sent over after signing up to the research and this was followed by an invitation to complete the pre-course worksheet. During the pre-course worksheet, the students were asked to go to a forest to activate the metaphor. The worksheet asked them to capture thoughts on how and when nature inspired them as well as to observe how different entities in the forest interact with each other. The second survey was sent to the participants after the workshop.

### *Data analysis*
The qualitative data was analysed according to grounded theory (Bryant et al., 2007). All responses were coded and clustered.

For example, when participants were asked what insights from the forest metaphor were realistic to implement, one of the clusters was defined as "interconnectivity" based on the coding of the following answers:

- *"We need to understand that all elements of an organisation are connected, like the roots of the trees and the fungi networks, and therefore look at the system as a whole."*
- *"More thoughtful cooperation inside the organisation to reveal the potential of each employee and design interconnections internally."*
- *"The forest metaphor was helpful to consider the inter-connectedness of organisations and institution"*

## Results
### *Participants*
Most of the students were taking the course as part of their part-time studies. Participants declared to be in their 20s (4), 30s (7), 40s (9), 50s (6) and 60s (1). All participants were in employment during the time of the study. 14 out of the 27 participants work in "business", followed up by "policy" (3), "advisory" (3), "NGOs" (2), "academia and research" (2), "education" (2) and "finance" (1). When asked to self-assess their competencies related to the "circular economy" the participant's responses ranged mostly from moderately competent to competent.

### *Initial circular economy conceptualisation*
In the first survey, the participants were asked to choose between four experimental sentences that demonstrated two competitive metaphors and two forest metaphors. 24 students found that the following sentence resonated most with them: "By implementing circular economy, businesses can create a flourishing ecosystem to thrive in." as demonstrated in Figure 1.

25 Out of 27 participants were to some degree comfortable with a conceptualisation that follows the logic of the forest metaphor.

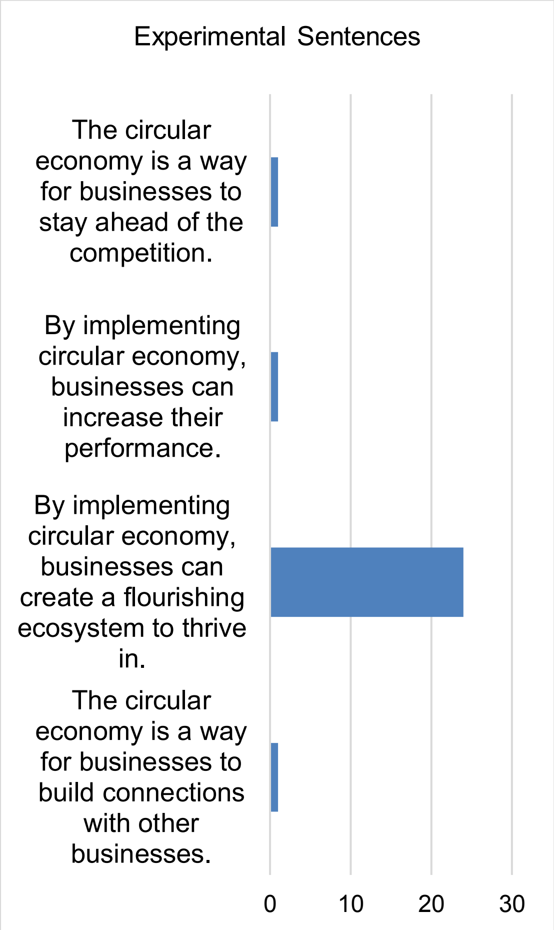

**Figure 1. Overview of the selection of the experimental sentences by the participants.**

When asked to elaborate on why they chose this sentence, participants mentioned alignment with their personal views, because they view businesses as part of an ecology, and because it refers to the conditions for life as a starting point for thinking about the economy.

Only two participants selected an experimental sentence that displayed a competitive metaphor. The main reason for their choice is that they believe business needs to act sustainably to ensure that they can stay ahead of the competition and increase their performance.

After the selection of the experimental sentences above, the participants were asked if they thought most individuals in their organisation would agree with them. 11 Participants expect they would, and 16 participants were either unsure or did not expect they would agree with them. The main reason why participants were unsure about the stance of other individuals in the organisation is due to a lack of knowledge, interest, or awareness about the circular economy. The second reason was that they expect that others would value competitive features more and prefer the most profitable way possible.

*Metaphor activation*
Before the course officially started, the participants were asked to venture into a forest and complete an experiential learning worksheet. Most participants confirmed that they were able to complete this exercise, but some experienced challenges accessing an ecosystem such as a forest when residing in an urban area.

The purpose of this element of the course was to activate their present knowledge about the forest, which helps them prepare for the workshop during the course. During this exercise, features were prompted around interdependency, connectivity, resilience, and symbiosis.

*Workshop experience*
After the workshop, most participants agreed or somewhat agreed that engaging with the forest metaphor had been enriching and brought new insights. The graph in Figure 2 shows that participants agreed that the metaphor has been enriching. However, this response was less strong for the insights that this metaphor brought to them.

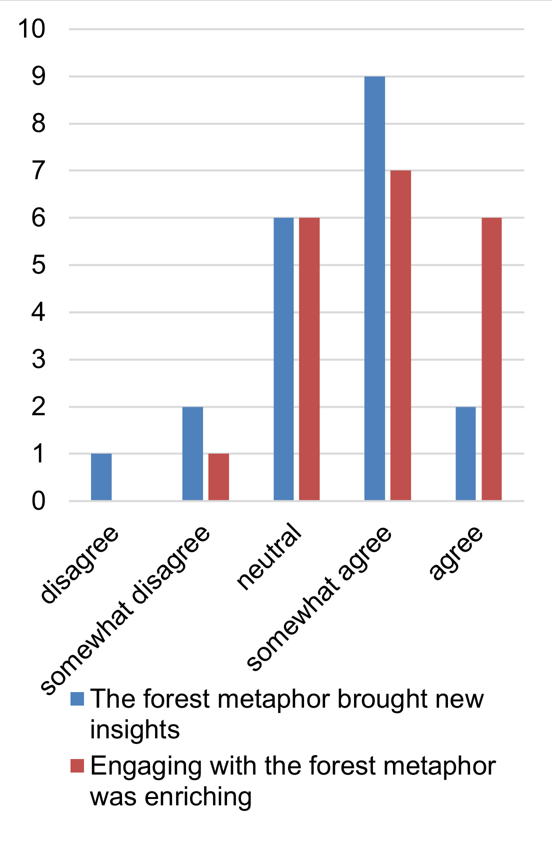

**Figure 2. A comparison of the result of the statements: "the forest metaphor brought new insights" and "engaging with the forest metaphor was enriching".**

When participants were asked to elaborate on this, qualities like the interconnectedness of organisations and institutions were mentioned most frequently together with cooperation between different entities in the economy.

At the same time, most participants also felt tension between the insights of the forest metaphor and the reality of their business or organisation as indicated in Figure 3.

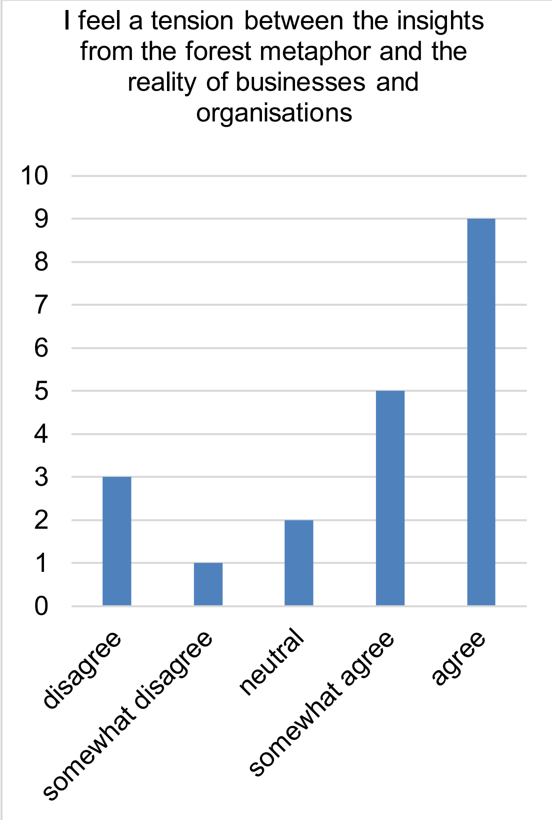

**Figure 3. There was a tension identified between the forest metaphor and the reality of businesses and organisations**.

*Conceptual development*

In the second survey, the experimental sentences were presented to the participants again and as expected, a similar outcome was generated to the pre-course survey.

In a later question, as visualised in Figure 4, the participants expressed that they either found their understanding or conceptualisation of a circular economy unaffected or deepened.

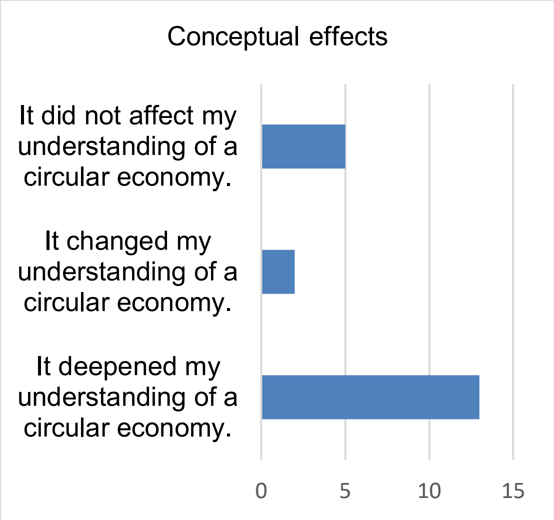

**Figure 4. The conceptual effects of the learning experience.**

*Features of the forest metaphor*
Finally, the participants were asked to review the principles of a regenerative economy (Fath et al., 2019) and rate how relevant they find the forest metaphor for this principle.

The forest metaphor has been rated between somewhat relevant and very relevant for all principles by the participants. This indicates that there could be a shared understanding of the forest metaphor that would be in line with the idea of a regenerative economy.

## Discussion
Insights from the forest metaphor that stood out to the participants were mostly around the interconnectedness of organisations and institutions as well as cooperation between different entities in the economy. However, the participants of this study seem to face challenges applying the insights of the forest metaphor and most indicate a tension between the insights of the forest metaphor and the reality of their organisation.

To evaluate the nature of this so-called reluctance to accommodation, the four conditions for conceptual change from Strike and Posner (1982) are evaluated considering the engagement with the forest metaphor.

*Condition one and two*
The dissatisfaction with existing conceptions and the condition that the new conception must be intelligible are assumed to be met when the students signed up to the course since the sign-up page had a clear descriptor of the learning activities that would take place.

*Condition three*
The third condition requires that a new conception must appear initially plausible. Posner & Strike (1982, p.235) mention that *"a new idea […] is less likely to be accepted if it is inconsistent with current […] knowledge, or if it has no clear physical account"*. In other words, there could be a reluctancy in the acceptance of new conceptualisations if there is an inconsistency with other knowledge.

Cobern (1996) describes the phenomenon when learners isolate the concepts that do not fit their natural way of thinking (see Figure 5). After pressure is relieved, such as an exam or occasion where the new concept was fruitful, the conception deteriorates, and the learner reverts to their natural way of thinking. This is due to the pressure and orientating effect of the overall worldview.

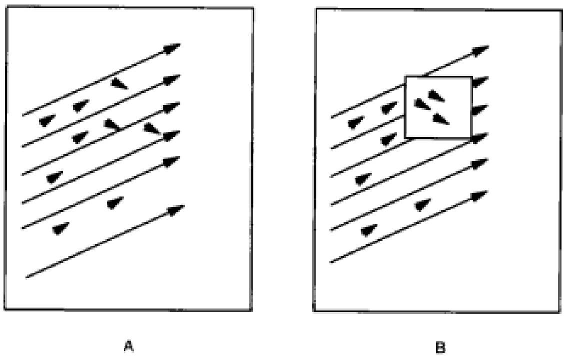

**Figure 5. the orientating effect of worldview (Cobern, 1996).**

Insights from the forest metaphor could be conflicting with the participants' current conceptualisation of the relationship between businesses in a circular economy and lead this cognitive isolation. However, in the pre-course survey, it was identified that 25 out of 27 participants were comfortable to some degree comfortable with the logic of the forest metaphor. This could be further and more robustly investigated but it suggests that to some degree their worldview could accommodate and support more nonlinear metaphors, such as the forest metaphor.

*Condition four*
The fourth condition is that a new conception should be fruitful. As part of the fourth condition,

*"the new conception must do more than solve its predecessors' difficulties. It should have the potential to be extended, to open up to new areas of inquiry."* (Strike & Posner, 1982, p.235). The participants claim that the engagement with the forest metaphor enriched their understanding of circular approaches, however, most also felt a tension between the reality of their organisation and the insights of the forest metaphor.

This was especially expressed by participants that felt that the competitive nature of the company would always receive priority. During the workshop, participants raised how some of the insights seemed unrealistic to their specific context. One of the participants raised the recent cases where ESG - Environmental, Social, Governance - collaboration has been accused of violating anti-trust laws (O'Sullivan, 2023). Several others raised the importance of their shareholder responsibility would be a barrier to several of the features of the forest metaphor.

## Pedagogical implications

The fourth condition around the fruitfulness of the conceptualisation particularly requires attention from a teaching perspective, since participants raised challenges when applying the insights into their business context.

Strike and Posner (1982) suggest that the teacher should take the role as Socratic tutor. A traditional interpretation of Socratic practice leads to a situation where the teacher insists on consistency among beliefs and confronts learners with the implications of their thoughts through a dialogue. However, a more contemporary practice of a Socratic exchange is used as a teaching method for critical thinking (Boghossian, 2006).

In the case of the use of the forest metaphor to make sense of the relationship between businesses in a circular economy, this could mean that the teacher is part of an exchange with the learner to seek specific areas where their ideas could align with the reality of their business or organisation.

## Conclusion

This study aimed to evaluate to what extent the forest metaphor allows students to rethink the relationship between businesses in a circular economy. The forest metaphor was chosen due to its features around balancing competition and interdependency, which could lend itself well to an alternative conceptualisation of businesses in a circular economy. The study was addressed through a case study of a course which attracted students that seemed comfortable with the logic of the forest metaphor.

The engagement with the forest metaphor in the context of the circular economy was considered enriching by the participants. It seemed relevant to the principles for a regenerative economy by Fath et al. (2019). Therefore, the initial insights that come with the forest metaphor could be considered a promising line of enquiry in the development of a conceptualisation of a circular economy inspired by a nonlinear metaphor.

However, most participants experienced tension between the insights of the forest metaphor and the reality of businesses and organisations. When asked about areas where they were able to implement insights from the forest metaphor, many were not able to identify clear areas within their business or organisation. This tension mostly affects the fruitfulness of the new conceptualisation and requires attention from a teaching perspective.

This could mean that more practical features from the source domain (the forest) could be proposed to the learner when engaging with this metaphor. Learning through a Socratic exchange may support in identifying more concrete areas for the application of this metaphor in a circular economy business context.

Further research could explore areas within the target domain of sustainable business where specific insights from the forest domain are fruitful and applicable.

## Acknowledgements

The authors would like to thank Ellen Mumford from the University of Cambridge Institute for Sustainability Leadership for her project management of the course.

# The influence of dynamic norms on the effectiveness of sufficiency-promoting messages

**Maike Gossen[a], Josephine Tröger[b]**
a) Technical University Berlin, Berlin, Germany
b) Fraunhofer Institute of Systems and Innovation Research ISI, Karlsruhe, Germany

**Keywords**: Sufficiency, Dynamic Norms, Online media, Mobile phones, Communication.

**Abstract**: Excessive consumption is a significant threat to the environment. The sufficiency strategy aims to reduce consumption by targeting individual behavioral changes. For mobile phone choices, this reduction can be achieved by not buying new devices and extending the life span of existing ones. Companies have a responsibility to support sufficiency-oriented mobile phone use. We investigated the effectiveness of sufficiency-promoting communication and the use of dynamic norms in behavior-change interventions in an online experiment. Results showed no significant effects of a sufficiency-promoting message emphasizing a dynamic norm compared to two other conditions. Our results confirm the limited effectiveness of interventions based on dynamic norms but offer important clues for the design of future sufficiency-oriented communication.

## Introduction

As environmental problems such as climate change and biodiversity loss have become more pressing, both practice and academia have started focusing attention on the need to shift to sustainability. While many advocate incremental changes in efficiency and technological solutions, others promote a sufficiency approach (O'Neill et al., 2018; Lorek and Spangenberg, 2019; Vita et al., 2019; Jungell-Michelsson and Heikkurinen, 2022).
Most scholars understand sufficiency as a strategy to reduce absolute consumption levels on various levels of the society. Sufficiency includes behaviors, such as absolute reductions, modal shifts, product longevity, and sharing practices (Sandberg, 2021). Furthermore, sufficiency requires a change in personal norms and values that foster ways of lower consumption in many fields of everyday behavior, such as clothing (Joanes et al., 2020) or the use of technical devices Currently, not much is known about how business actors can accompany and support the relatively radical change in current consumption patterns – including a fundamental shift in their own sale and marketing principles as sufficiency contradicts the current growth paradigm many companies follow. However, businesses have a responsibility to work toward the broader socio-economic transition to sustainable lifestyles required to stay within planetary boundaries as they have a major impact on the products and market conditions that drive consumption (Lage, 2022).

In fact, companies can influence consumer behavior through sufficiency-promoting marketing and help to reduce consumption levels (Gossen et al., 2019; Bocken and Short, 2020). However, short-term information and communication measures alone do not seem to be sufficient to promote sufficiency-oriented intentions or behaviors (Frick et al., 2021; Tröger et al., 2021). Therefore, we need to consider other relevant variables such as social influences.

Social influences are relevant to various pro-environmental intentions and behaviors. For instance, social norms (the unspoken rules of conduct in a given context) and more specifically their dynamic component (showing a trend in a certain direction) have recently been found to be effective in changing pro-environmental behaviors (e.g., Sparkman and Walton, 2017). However, there is limited evidence on the effects of dynamic norms on sufficiency-oriented behaviors. To advance knowledge about the influence of dynamic norms, we investigate sufficiency-oriented mobile phone use as a target behavior and various norm framings in der effectiveness regarding intention and behavior change.

## Conceptual Considerations

A popular way of achieving behavior change is to introduce communications that draw attention to specific social norms. Social norms are general standards of behavior and attitudes within a particular social group (Sunstein, 1996). They affect a wide range of individual attitudes, choices, and behaviors. Research shows that people respond more positively to a behavior when there is social proof for it (Cialdini, 2009) – yet they are also unaware of such influence (Nolan et al., 2008). Further, evidence shows that social norms can be strong predictors of pro-environmental behaviors (Farrow et al., 2017). However, the effectiveness of using norm-based interventions is still unclear and remains inconsistent (e.g., Abrahamse and Steg, 2013; Yeomans and Herberich, 2014; Anderson et al., 2017).

Research on social influence strategies distinguishes between social norms that refer to other people's actual behavior (descriptive norms) and norms that refer to people's beliefs about how they should behave (injunctive norms; Cialdini, 2012). Within the category of descriptive norms, static norms (describing a current status quo) and dynamic norms (emphasizing that a norm is currently changing and more people are moving toward a certain behavior) can be distinguished (Loschelder et al., 2019; Sparkman and Walton, 2017). Dynamic norms, then, emphasize that social norms are constantly changing with more people exhibiting a particular behavior in a relevant target domain (Sparkman and Walton, 2017). These norms are considered particularly effective when the desired behavior is freely chosen, violates the norm (as in the case of sufficiency, which contradicts the prevailing norm of overconsumption), and when the situation is ambiguous or novel (e.g., Cialdini 2009). Moreover, dynamic social norms can motivate a wide range of sustainable behaviors without relying on social pressure (Sparkman et al., 2021; Boenke et al., 2022). Therefore, we investigate the following research question:

**How does a sufficiency-promoting message that emphasizes a dynamic norm influence consumers' actual sufficiency-oriented mobile phone intentions and behavioral choices?**

Based on previous studies (e.g., Sparkman & Walton, 2017; Carfora et al. 2022; Loschelder et al. 2019; Boenke et al. 2022), we hypothesize that a dynamic norm would increase both intentions and behavioral choices related to sufficiency-oriented mobile phone use if the message was sent by an independent source such as a scientist.

**H1.** People who receive a sufficiency-promoting message emphasizing a dynamic norm show lower intention to buy a new mobile phone and a higher intention to sufficiency-oriented use of mobile phones than people receiving a sufficiency-promoting message that does not emphasize a dynamic norm or a consumption-promoting message.

**H2.** People who receive a sufficiency-promoting message emphasizing a dynamic norm less often choose to purchase a new mobile phone (i.e., show more sufficiency-oriented behavioral choices) than those receiving a sufficiency-promoting message that does not emphasize a dynamic norm or a consumption-promoting message.

## Method

The study was conducted as an online experiment. Data were collected by a market research organization as part of its online access panel in August 2022. Only participants who shopped online several times a year and used a search engine at least once a week were included. To ensure representativeness, a socio-demographic distribution was chosen that is representative of the part of the German population that uses the Internet frequently (Destatis, 2022). After data cleaning, the total sample size was N = 996. Participants were randomly assigned to one of six conditions using a three-by-two multifactorial design. The first factor was the type of message presented to participants and varied in three levels: sufficiency-promoting message (experimental group 1 (EG1)), sufficiency-promoting message emphasizing a dynamic norm (experimental group 2 (EG2)), and consumption-promoting message (control group (CG)). The other factor was the type of sender from which the participants received the message, however corresponding hypotheses and results are not part of this conference paper.

The manipulation included the three communication variants, each consisting of three info-boxes. Regardless of the condition, all info-boxes were designed identically. Only the text in the message varied between conditions. For the sufficiency-promoting message emphasizing a dynamic norm (EG2), the claim was "In collaboration with scientists, we found out …" because we wanted to take advantage of the positive effect of norm-oriented messages sent by a researcher, which has been demonstrated by previous research (Boenke et al., 2022). An example of a selected info-box in the three communication versions is shown in Figure 1.

**Figure 1. Condition wise manipulation material from left to right: (1) EG1: Battery low, display scratched, socket broken? Repair instead of buying new. Extend the life of your mobile phone. Book a repair now. (2) EG2: Battery low, display scratched, socket broken? In collaboration with scientists, we have found that more and more people are extending the life of their mobile phone by getting it repaired. Book a repair now. (3) CG: Battery low, display scratched, socket broken? Don't miss out on attractive bargains on a new mobile phone. Shop now**.

To measure *sufficiency-oriented mobile phone intentions*, four items were used, adopted from Rausch & Kopplin (2021), and reworded based on Sandberg's (2021) sufficiency-oriented behavior typology. Based on an exploratory factor we formed an index of sufficiency-oriented mobile phone intention and one single item measuring the intention not to buy a new mobile phone

*Sufficiency-oriented mobile phone choice* was measured using a voucher question adapted from Frick et al. (2021). Participants could choose between a voucher for a popular retail store for electronic products or three sufficiency-oriented options: an online marketplace for remanufactured electronic products, an online service for electronic device repairs, or a donation to a non-governmental organization. The dichotomous variable was the choice of sufficiency-oriented options or stating "I do not want to consume," coded as 1, and the choice of the regular online store voucher, coded as 0.

We assessed the *socio-demographic variables* gender (male = 463, female = 530, diverse = 3), age in years ($M$ = 42.86, $SD$ = 14.28 ), education level in five categories (50% of the participants had a German Abitur (high-school leaving certificate) or higher), and income in nine income categories ($M$ = 4.84, $SD$ = 2.63; with 50% of the participants indicating an income between 3,000 and 3,500 €, i.e., category five, or higher).

## Preliminary Results

For H1, we analyzed $N_{EG1}$ = 365 receiving a sufficiency-oriented message only, $N_{EG2}$ = 215 receiving the sufficiency-oriented message emphasizing a dynamic norm, and $N_{CG}$ = 416 receiving a consumption-promoting message. We ran a one-factor ANOVA to test whether people who received a sufficiency-promoting message emphasizing a dynamic norm had lower intentions to buy a new mobile phone and a higher intention toward sufficiency-related use of mobile phones than people who saw sufficiency-promoting only or consumption-promoting messages. The main effect of the group is statistically not significant for the intention to buy a new mobile phone ($F(2, 993) = 1.35$, $p = 0.261$; $\eta^2 < .001$, 95% CI [0.00, 1.00]). Likewise, the intention toward sufficiency-related use of mobile phones was not significant ($F(2, 993) = 1.20$, $p = 0.302$; $\eta^2 < .001$, 95% CI [0.00, 1.00]). These results disconfirm H1.

To test H2, we excluded participants who refused to participate in the raffle resulting in divergent sample sizes for each group: $N_{EG1}$ = 330, $N_{EG2}$ = 198, and $N_{CG}$ = 369. We ran a Chi-square test of independence to compare participants' behavioral choices. There is no significant difference between the groups, $\chi^2(2) = 4.84$, $p = .089$. The share of participants who chose a sufficiency-oriented voucher is highest in EG2, (i.e., 34.8%), followed by EG1 (i.e., 29.1%). The CG shows the lowest sufficiency-oriented behavioral choice (i.e., 26.8%, see also Table 1 for the group-wise descriptive results of the behavioral choices). In addition, we fitted a logistic regression model (estimated using ML) to predict behavioral choice within Group. However, the model's explanatory power is weak (Tjur's $R^2 = 0.005$). Thus, **H2** must be rejected.

| Group | Sufficiency-oriented choice | *N* | Percentage |
|---|---|---|---|
| EG1 | no | 234 | 70.9 |
| EG1 | yes | 96 | 29.1 |
| EG2 | no | 129 | 65.2 |
| EG2 | yes | 69 | 34.8 |
| CG | no | 270 | 73.2 |
| CG | yes | 99 | 26.8 |

**Table 1. Sufficiency-oriented mobile phone choice per group**.

## Preliminary Discussion of Theoretical Contribution

Consistent with a previous study by Frick et al. (2021), our results indicate that single, short-term communication interventions, even if they convey a normative message, are insufficient to influence sufficiency-oriented intentions and behavioral choices. Nevertheless, about a third of the people in all groups opted for a sufficiency-oriented coupon offered as part of a list of possible consumption options, regardless of which manipulation message they had previously seen (29.1% in EG1, 34.8% in EG2, and 26.8% in CG). We conclude that the participation in the survey itself may have had an effect which was also found in previous research (Tröger et al., 2021). People were thinking about their actual mobile phone use while participating. It has been shown that simply assessing consumption intentions can change subsequent behavior through awareness raising, at least in the short term. However, people's intentions and behaviors are often biased toward self-centered judgments, i.e., the better-than-average effect (Zell et al., 2020), which has also been noted for pro-environmental behavioral engagement (Bergquist, 2020), thus, may indicate that there would be no effect in real-world decisions

Short-term sufficiency-promoting messages may be less effective in online media for several reasons: One reason is that online media, such as online stores and search engines, often emphasize convenience, constant availability, quick access to consumer items, prominent placement of deals, and a simplified checkout, which shape consumer expectations (The Future Shopper Report 2022) and thus discourage people from considering the long-term consequences of their consumption choices. Another reason is that individuals are exposed to more options and offers in the online context, making it more difficult for them to make well-informed decisions. In addition, this abundance of products and services in online media, and the ability to simultaneously compare prices, features, and reviews on multiple channels can make it difficult for individuals to distinguish between truly necessary and unnecessary purchases. The sheer number of messages and the routine, fast-paced way people navigate the abundance of online information can make it difficult for messages promoting sufficiency-oriented alternatives to break through the noise and influence people's consumption decisions. In addition, while pro-consumption advertising is ubiquitous in online media, sufficiency-oriented content remains a rare phenomenon in social media and online advertising (Frick and Matthies, 2020). It is unlikely that these scattered and infrequent messages will lead to short- or even long-term behavior change, as has also been shown in Young et al. (2017), Frick et al. (2021), and Tröger et al. (2021).

This work also contributes to the mixed findings of research on the social normative influence on sustainable and sufficiency-oriented behavior and enriches knowledge about the design of successful behavior change interventions. A recent literature review on interventions to reduce meat consumption identified personal, sociocultural, and external factors as central to behavior change (Kwasny et al., 2022). The review showed that, while interventions targeting personal and external factors are promising approaches, there is less evidence that interventions targeting sociocultural factors such as social norms promote positive behavior change. Our study in another behavioral domain confirms the limited effectiveness of interventions based on social norms at least in an experimental setting. Thus, our results are consistent with other empirical studies that did not provide clear evidence of the influence of dynamic norms on sufficiency-oriented behavior, limiting the potential of normative approaches to make behavior more sustainable (Aldoh et al., 2021; Lee and Liu, 2021; Çoker et al., 2022).

Espoo, Finland - 31 May - 2 June 2023

# What measuring the environmental impact of Circular Business Models means for the clothing industry

**Sarah Gray[ab]; Professor Angela Druckman[b]; Professor Jhuma Sadhukhan[b]; Keith James[a]**
a) WRAP, Banbury, United Kingdom
b) University of Surrey, Guildford, United Kingdom

**Keywords**: Circular business models; Reuse; Resale; Rental; LCA.

**Abstract**: The aim of the research presented here was to compare a selection of circular business models (CBMs), to find out whether they offer potential to reduce the environmental impact of the clothing sector. Life Cycle Assessment (LCA) was used to compare the environmental impact of clothing in the average wardrobe of a UK adult. Data were provided by a consumer survey to update information about garment lifespans and to provide new information about how CBMs are accessed and used to provide clothing for the UK wardrobe. This data, combined with existing LCI data, were used to measure the environmental impacts of five CBMs, taking into account the burdens due to the activities associated with the CBMs as well as potential environmental savings. Acquiring half the outerwear in the wardrobe using each of the five CBMs in turn, was found to reduce environmental impact compared to a conventionally acquired wardrobe. Contributions of different use phase activities were analyzed to improve the data available to inform the ways CBMs are used.

## Introduction

It was recognized at the Paris Agreement in 2015, that to keep the world within 1.5°C on average of global warming, it was necessary to cut greenhouse gas emissions to close to zero by 2050 (UN, 2015). Since then, the UN's Fashion Charter has set out the steps that are needed to reduce the climate impacts of the fashion industry, and seeks to join up efforts of various voluntary initiatives, such as WRAP's Textiles Action Networks (UNFCCC, 2021, 2020). There is a real challenge, despite the commitments that have been made, for industry and policy-makers to move far enough, fast enough as the goal to limit warming to 1.5°C already looks unlikely to be achieved (IPCC, 2021). The full life span of clothing has a high climate impact due not only to raw material extraction, but various production processes and the unsustainable rate of consumption of new clothing (Niinimäki et al., 2020). The high environmental impacts associated with clothing also extend to water use and pollution, toxicity impacts and land use (Manshoven et al., 2019; Roos et al., 2019).

Research has shown that the environmental impacts of clothing may be reduced through reuse, or by increasing use, of garments, because some of the impacts due to the raw materials and production can be avoided by replacing sales of new items with circular business models (CBMs) (Fisher et al., 2011; Thomas et al., 2012; WRAP, 2017, 2011). Previous life cycle assessments (LCAs) provide a variety of case studies from CBMs that assess the impact of rental and resale business models (Johnson and Plepys, 2021; Levanen et al., 2021; Zamani et al., 2017). There are, however, many garment types that are not included in the existing literature on environmental impacts of reuse. An LCA for the whole wardrobe could offer new insights about the potential to use different business models for clothing worn for different purposes (Piontek et al., 2019). The aim of the research project was to compare a selection of CBMs, to find out whether they offer potential to reduce the environmental impact of the clothing sector. The research has sought to identify and improve existing data about the impacts of CBMs given a range of scenarios and by considering the impacts of the average wardrobe of clothing in the UK.

## Method

LCA was used to compare a selection of five different CBMs. The business models included in the LCA were subscription leasing; short-term rental; commercial resale; charity resale; and online resale. The first stage of an LCA is the goal and scope. The scope of the study was designed to inform decision-making by the clothing sector in the UK. A database was compiled with this broad scope in mind, which included nationally representative survey data about the clothing in the wardrobe for consumers in the UK (sample size 6,000 UK adults), and the use of CBMs (sample size 2,000 UK adults) (WRAP, 2022). Primary data for the Life Cycle Inventory (LCI) focused on activities that would be in the foreground of the model for clothing acquisition and use based on the consumer survey by WRAP, together with findings from a series of interviews carried out with CBM business owners and experts (Gray et al., 2022; WRAP, 2022). Processes not in the foreground related to raw material extraction, production and disposal; data from secondary sources were used including various published LCIs and LCAs, as well as the Ecoinvent database (v3.7.1) (Joyce and van Santen, 2019; Munasinghe et al., 2021; Roos et al., 2016; Thomas et al., 2012; Van Der Velden et al., 2014; Wernet, G., et al., 2016). Clothing consumption data and information about the environmental impacts of clothing use were also included from existing sources (Beton et al., 2014; Laitala et al., 2018; Sandin et al., 2019). The impact indicators chosen are listed in Figure 1. ReCiPe Midpoint Hierarchist indicators were used to cover a range of impacts on the environment (Huijbregts et al., 2017; RIVM, 2017). The Life Cycle Impact Assessment was carried out using SimaPro (v9.2.0.2) and the results compiled in Excel. These results were shared with the Textiles 2030 Metrics Working Group, part of a voluntary agreement of the UK textiles sector.

## Results

Results from the consumer survey provided data about the average UK wardrobe. Information gathered included the numbers of different types of garments, types of businesses they were acquired from, the lifespan of those garments, likelihood that the garments had been repaired and the impact of this on lifespan (WRAP, 2022). The results from the survey indicate the potential lifespan of secondhand garments was longer than garments bought new (WRAP, 2022). The survey research also found variation in how often a secondhand acquisition would displace the sale of a new product, depending on the type of CBM, with average displacement rates varying from 42% for subscription / leasing, to 54% for resale (WRAP, 2022).

The environmental impacts of garments acquired in a conventional wardrobe in the UK were compared to five alternative scenarios, represented by the five business models listed above. In each scenario, half of an average UK wardrobe was replaced with garments acquired using one of the CBMs. The results in Figure 1 show the conventional wardrobe had the highest environmental impact across a range of impact indicators including global warming, land use and water consumption.

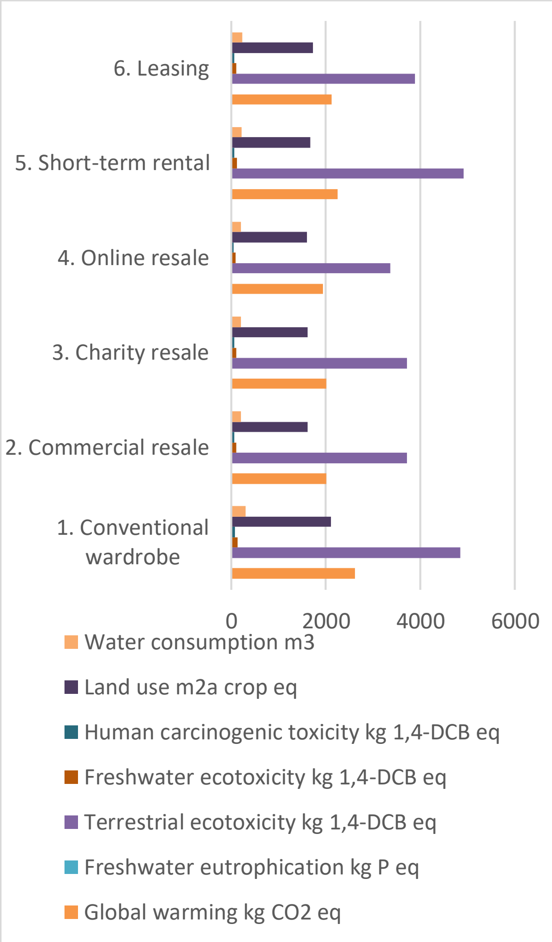

**Figure 1. LCIA results comparing the conventional wardrobe with 5 alternative business models.**

Contribution analysis makes it possible to look at the impact due to specific activities in the system. In this case the use phase of garments was of greatest interest and the systems described represent wardrobes with half the outer garments acquired using various CBMs. A contribution analysis of different activities in the use phase is provided for global warming potential (in kg CO2e) in Figure 2; and in Figure 3 the contribution analysis is repeated with customer transport excluded from the results.

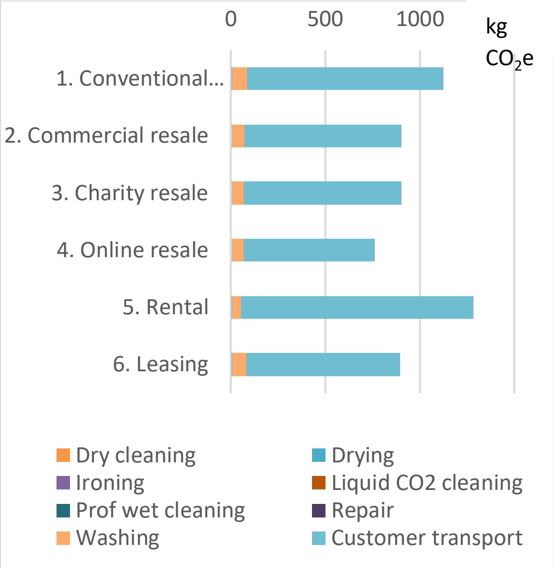

**Figure 2. Contribution analysis showing GHG emissions from use phase only.**

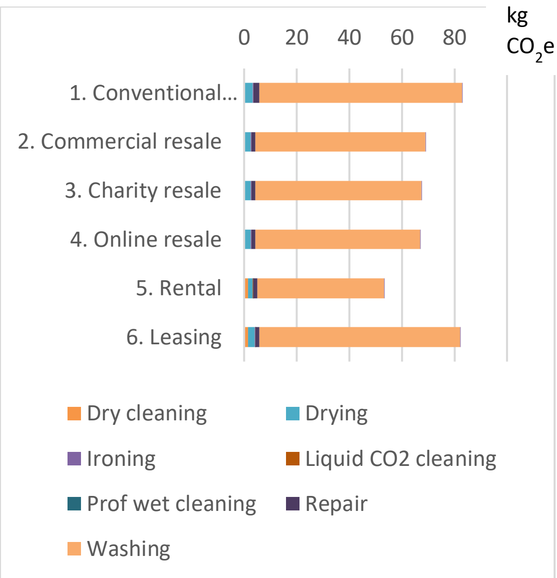

**Figure 3. Contribution analysis showing GHG emissions from use phase, excluding customer transport impacts.**

Figure 2 shows that customer transport makes by far the largest contribution to greenhouse gas emissions, and this is the case irrespective of which type of business was used to acquire garments. In Figure 3 the highest greenhouse gas emissions from the use phase, with customer transport emissions excluded, were due to domestic washing. All of the business models compared show the same activities were dominant, despite the data and assumptions used to describe use varying between them. Looking only at the contribution of activities in the use phase, the short-term rental business model had the highest GHG emissions in Figure 2, but the lowest GHG emissions in Figure 3 once customer transport was excluded.

New business models provide existing retailers with solutions that can help them provide for reuse, and an increase in the number of times that products are used, by working in partnership with CBMs. The consumer research that was carried and data gathered from literature and in-depth interviews made it possible to create a database to provide the basis for carrying out a comparative LCA of CBMs. Contribution analysis has identified activities during the use phase which have the highest GHG emissions. However, it is unlikely that the same results would be obtained with different case studies used to represent each of the CBMs, or with varying input data such as customer transport distances and modes of transport. Using the database that has been developed, further scenario analysis can be used to test the level of variation in the results. Such analysis will be useful to support decision-making about how to operationalize the CBMs and what recommendations to provide to businesses and consumers about ways to minimize their environmental impacts. New case studies using examples of each of the CBMs could also provide valuable insights about the effect of using one CBM or another in different circumstances, and the potential benefits of changing various aspects of the CBM. For example, should a CBM intent on reducing the environmental impacts associated with its business, focus on reducing delivery distances between the business and the customer; using vehicles with low emissions; or using more durable garments and repairing them so that they can be worn a greater number of times overall?

Data provide for better decision-making and evidence provision to the UK's Textiles 2030 voluntary agreement. The data used for the LCA presented here take into account both the burdens due to the activities associated with the CBMs, as well as savings that they can help bring about. Each of the CBMs included in the results can reduce the environmental impacts of clothing, compared to garments acquired using conventional routes in the UK. They do this by extending the lifespan of the garments in use and displacing some of the impacts of primary production, as long as the impacts due to the CBMs do not outweigh the displaced impacts. However, the potential benefits can only be achieved if the CBMs are adopted by businesses and then taken up by consumers. There is a need for wider recognition and take-up of CBMs and for retailers and brands to work together with new business models.

In the context of company reporting, the impact of purchased goods and services is significant (UNFCCC, 2020). Reporting scope 3 emissions, which includes these impacts as well as customer transport and the disposal of goods (WRI & WBCSD, 2011). The ways that garments are used and decisions about how to acquire them, care for them and dispose them can make a real difference to the impacts of those goods (Laitala et al., 2018), and to the indirect impacts due to activities of retailers and brands who place them on the market. It is also important that the environmental savings of circular economy initiatives are not taken for granted (Mayers et al., 2021). There is an ongoing need for measurement of impact due to CBMs if these are to replace a proportion of sales of new products. The information gathered is needed to improve decision-making about how best to operationalize CBMs (Gray et al., 2022). It is also needed to help ensure potential savings actually are provided.

## Conclusions

Retailers often omit the use phase and disposal when measuring the impacts of their products. This failure to report on the full life cycle means that they are not only unable to take full responsibility for the emissions due to their products, but also have less reason to switch to a more responsible way of doing business. Data about the environmental impact of CBMs are needed to inform decision-making. This research has shown that each of the CBMs considered has potential to reduce the environmental impacts associated with the average wardrobe in the UK. The data gathered improves data available about garment use phase in the UK with respect to secondhand clothing distributed through resale, and with respect to access-based business models such as short-term rental and leasing. It is also possible to see from the results that some activities in the use phase are likely to contribute much more to climate impacts than others. When switching to CBMs, changing the way that garments are sold and how they are distributed can change the results. Improving outcomes from CBMs over time will entail the ongoing monitoring and reporting of environmental impacts combined with action to configure CBMs in ways that avoid or reduce emissions from the activities that contribute the most to the overall life cycle of clothing.

# Mapping the potential intended and unintended consequences of Circular Economy policy measures: the common charger initiative

**Daniel Guzzo [(a)], Stine M. B. Rasmussen [(a)], Daniela C. A. Pigosso [(a)]**
a) Technical University of Denmark (DTU), Department of Civil and Mechanical Engineering, Lyngby, Denmark

**Keywords**: Public policy, Unintended consequences, Rebound effects, Lock-ins, System Dynamics, Systems Thinking.

**Abstract**: The Circular Economy Action Plan (CEAP) is a critical policy framework to facilitate the CE and sustainability transition in the European Union. However, unintended consequences can hinder the success of such policies. This research explores the potential intended and unintended consequences of a policy initiative within the CEAP (the common charger for mobile phones) by employing qualitative System Dynamics (SD), i.e. Causal Loop Diagrams (CLD). The results of the analysis draw on four interconnected CLDs that show relevant intended and unintended consequences of the measures within that initiative. Furthermore, the CLDs put several paradoxes of sustainability-oriented innovation into perspective, such as rebound effects (RE), unintended consequences, lock-ins, and ripple effects. Mitigation recommendations are drawn from the analysis. Finally, the study highlights the potential of using CLDs for evaluating policy measures and preventing unintended consequences.

## Introduction

By redirecting and accelerating innovation efforts, policies are essential elements of sustainability transitions (Bergek et al., 2008; Kivimaa & Kern, 2016; Rogge & Reichardt, 2016). Specifically, policies like the Circular Economy (CE) Action Plan (European Commission, 2020) can facilitate CE transitions by (I.) addressing resource use in different life cycle stages; (ii.) harmonising existing regional measures; (iii.) addressing specific characteristics of the member states' governance; and (iv.) considering the critical role of business in implementing change (Domenech & Bahn-Walkowiak, 2019; McDowall et al., 2017; Milios, 2018).

Nevertheless, the absolute outcomes of policies are not always achieved due to potential unintended consequences. Unintended consequences (such as rebound effects (RE) and technological lock-ins) hinder the policy's ability to achieve its goals (Aminoff & Sundqvist-Andberg, 2021; Castro et al., 2022; de Gooyert et al., 2016; Laurenti et al., 2016), often leading to full or partial policy failure. Meanwhile, current research approaches are limited to reflecting the complexity and dynamics of policy implementation, hindering the proactive evaluation of potential sources of policy failure and their effects (Raven & Walrave, 2020; Rogge & Reichardt, 2016).

Therefore, this research aims to map the potential intended and unintended consequences of policy measures through the use of qualitative System Dynamics (SD), i.e., Causal Loop Diagrams (CLD). CLDs are employed to articulate an endogenous causal understanding by supporting the identification of multiple cause structures and feedback loops (Barlas, 2002; Lane, 2008).

A model-based case study investigates one specific initiative of the CE Action Plan (CEAP) related to the common charger for mobile phones. The CLDs make explicit the intended consequences of the common charger measures alongside the RE, technological lock-ins, and other unintended consequences that might emerge from policy implementation. Finally, recommendations are drawn from the analysis for preventing the identified unintended consequences.

## Research approach

The research followed a model-based case study (Kopainsky & Luna-Reyes, 2008; Schwaninger & Grösser, 2008) to evaluate the

potential effects of implementing the CEAP. The intended and unintended consequences of implementing the common charger initiative were formalised through CLDs, focused on feedback thinking (Sterman, 2000, 2001).
Seven informants were interviewed, and ten documents were analysed as secondary sources of information:

- Official EU proposal (European Commission, 2021a)
- Official communication (European Commission, 2021b; European Parliament, 2022a, 2022b)
- Professional association comment (The App Association, 2019)
- Media communication (Chadwick & Tidey, 2022; Innocenti & Peitz, 2022; The Economic Times, 2021)
- Company-commissioned studies (Basalisco et al., 2022; Dahlberg et al., 2019).

| IF | Role |
|---|---|
| A | Economics consultancy director and PhD in economics focused on regulatory and impact assessments |
| B | PhD student and specialist in take-back systems and circular economy |
| C | Professor and expert on the circular economy, repair, and product lifetime |
| D | Director in an electronics industry association |
| E | Head of environmental policy in an industry association |
| F | Head of sustainability of a retail store chain |
| G | Sustainability coordinator of a retail store chain |

**Table 1. Informants (IF) interviewed in the investigation.**

In addition, existing references of well-known RE and unintended consequences within the electronics industry (Gossart, 2015; Laurenti et al., 2015; Rivera et al., 2014) and general sustainability action (Brockway et al., 2021; Colmenares et al., 2020; Lange et al., 2021; Metic & Pigosso, 2022) complemented the analysis.

Building the CLDs involved mapping the textual and verbal explanations into structures of variables and causal relationships that helped demonstrate and explain the potential effects of the measures (Barlas, 2002; Lane, 2008). Ambiguity was avoided by making explicit elements, relationships, and time delays. When possible, feedback loops – i.e., successions of cause-effect relations that start and end in the same system element that lead to specific patterns of behaviour (Barlas, 2002) – were made explicit. The analysis of the documents and informants' perspectives sustain four CLD models that describe the potential effects of the common charger initiative of the CEAP in the dynamics of resource consumption.

## Results

### *The common charger initiative for mobile phones*

The common charger initiative for mobile phones is constituted of regulatory measures on chargers for mobile phones and similar devices (European Commission, 2021a). The identified measures (M) are:

- Common wired charger
  - M1: Harmonise standards for wired charging (USB Type-C)
  - M2: Guarantee the same charging communication protocol for fast-charging devices to avoid harming batteries
- Purchasing decision
  - M3: Introduce requirements so end-users are not obliged to get a new charger whenever they purchase a new product
  - M4: Provide information about charging performance, characteristics, and compatible devices to end-users
- Other technologies
  - M5: Allow for future harmonisation (e.g., other than wired charging)

The intended and unintended ways in which these measures influence the dynamics of resource consumption are described in the following sections. Section 3.2 describes the intended consequences of regulating wired charging. Section 3.3 describes potential RE and unintended consequences of the measures. Section 3.4 describes the potential of the measures unlocking less regulated technologies. Section 3.5 describes the ripple effects of the initiative in the sector and other regions. Finally, Section 3.6 consolidates and connects the sub-models.

### *Sub-model 1: The intended consequences of regulating wired chargers*

Figure 1 depicts the intended consequences of regulating wired chargers. The *number of chargers produced* is determined by the *number of chargers per household* and the rate of *obsolescence of chargers*, leading to a certain amount of *material use from chargers* based on the *material efficiency of chargers*. Several factors determine the *number of chargers per household*: the *obligation to purchase charges*, the *number of charging interfaces, protocols and performance required by devices*, the *locations where consumers need charging*, and the *number of devices to charge simultaneously*. *General resource consumption* is not only defined by the *use of material from chargers* but also by the *use of energy from charging*.

The measures in the common charger initiative are designed to influence the *obligation to purchase chargers* (**M3**) and the *number of charging interfaces, protocols and performance required by devices* (**M1, M2, and M4**), which holds the potential to drive down the *number of chargers per household* – this is the intended outcome of the measure. Meanwhile, measures within the scope of the common charger have little influence on their obsolescence. Also, the measures seem to have little influence on behavioural factors for owning chargers, such as the *number of devices to charge simultaneously* and the *locations where consumers need charging*. The aforementioned finding was articulated by informant B, who expressed: "*It improves the flexibility around using the same charger for different products, but when you look at the amount of equipment that requires charging - from a laptop to an iPad, Notepad, phone, or watch – it is undergoing a lot of changes, and very fast. It is going to be influenced by that as well, and of course by the convenience.*" Therefore, although there is potential to decrease the number of chargers in households, it is unlikely to lead to only one charger per household.

### *Sub-model 2: Potential Rebound Effects and Unintended Consequences*

Figure 2 depicts the potential RE and unintended consequences of the measures. The intended effects of the common charger initiative (B1) are that *regulation* will drive down the *use of material* and *general resource consumption* by restricting the *number of chargers produced*. Nevertheless, this can unfold into two RE. First, eventually *increased available disposable income* from lower *costs to purchase chargers* might drive the *consumption of other products* up – characterising a re-spending rebound mechanism (R1). Second, concomitantly, eventual additional *producers' profits from chargers* due to lower *costs to produce the chargers* will lead to increased *production of other products* and additional *use of material* – characterising a re-investment rebound mechanism (R2). Both rebound mechanisms are considered for other products, as the likelihood of purchasing or producing additional chargers with the financial resources available is very low.

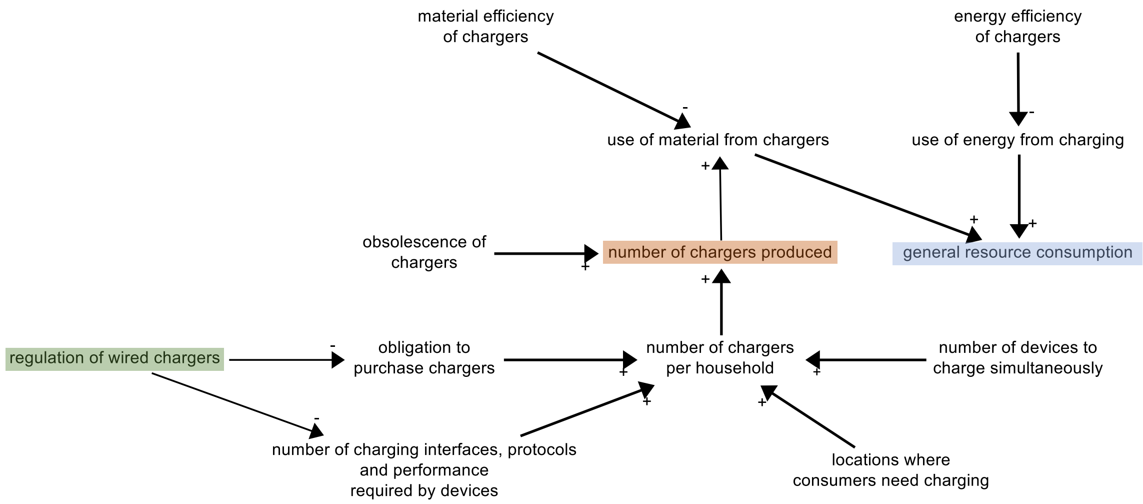

**Figure 1. Sub-model 1: CLD of the intended consequences of regulating wired chargers.**

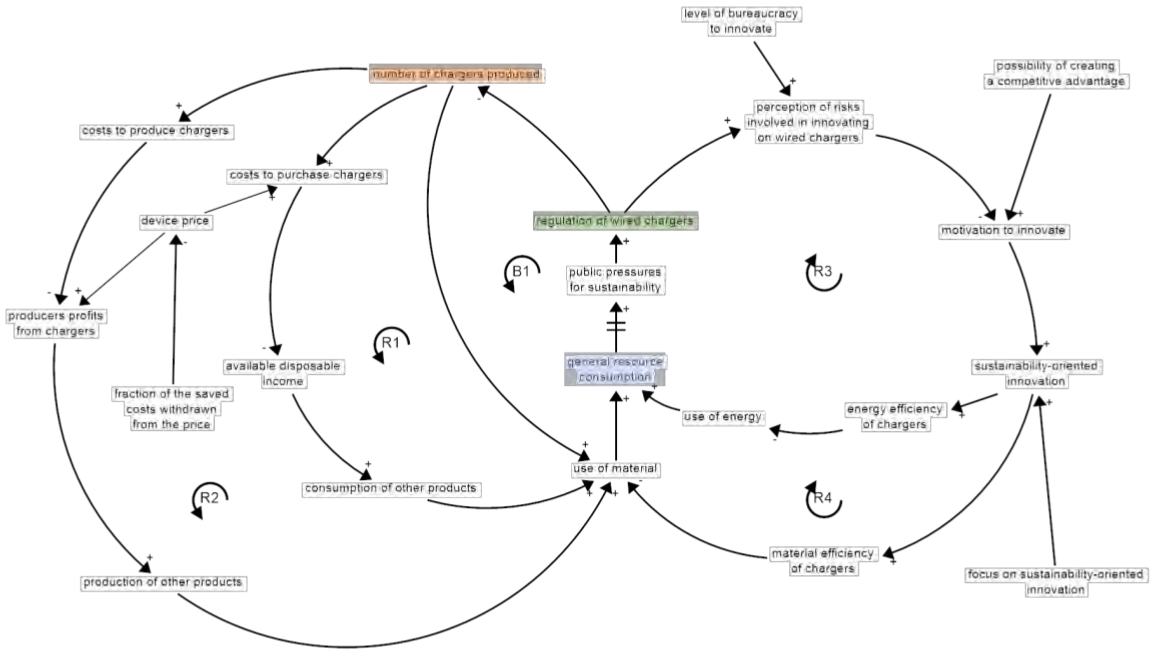

**Figure 2. Sub-model 2: CLD of the potential Rebound Effects and Unintended Consequences from measures.**

Two unintended consequences of implementing the common charger are that an *increased perception of risk in innovating on wired chargers* due to eventual higher *bureaucracy to innovate* can hinder the *motivation to* engage *in sustainability-oriented innovation*, restraining *the energy efficiency* and *material efficiency* of charging systems (R3 and R4). Informant B highlighted that companies seek to establish a competitive edge through innovation and differentiation: "*An area where it may have a negative influence is within the entire motivation for innovation and differentiation. When harmonising the chargers, a very important prerequisite is how you still allow innovation, which to me is a big challenge at the moment.*" In that case, even if fewer chargers are produced, those chargers might be less resource-efficient, leading to a lower-than-expected effect in general resource *consumption* both in terms of *material* and *energy*.

The identified rebound mechanisms (R1 and R2) rely on behaviour emerging from financial resources, while the unintended consequences (R3 and R4) rely on risk and motivation. An ingenious way to try and resolve these effects altogether is by creating mechanisms for preventing efficiency gains from being passed on to consumers (preventing R1) while influencing producers to use additional profits (preventing R2) to invest in innovation that will eventually create more material- and energy-efficient chargers (counterbalancing R3 and R4).

### *Sub-model 3: Unlocking less regulated technologies*

Figure 3 depicts the potential of the measures unlocking less regulated technologies. The *regulation of wired chargers* can also unbalance competing systems' innovation dynamics towards less regulated technologies. It may occur because, when two different technologies compete, the *attractiveness* and *expected profits* from each will influence companies' investment, which is limited. If only one of the technologies is *regulated* (with an associated *perception of risks*), companies will shift their investment to the other technology. Informant D raised concerns regarding the transfer of focus to less regulated domains: *"I fear that in a few years when the requirements are implemented, we will probably be charging wirelessly. And it is the interplay between*

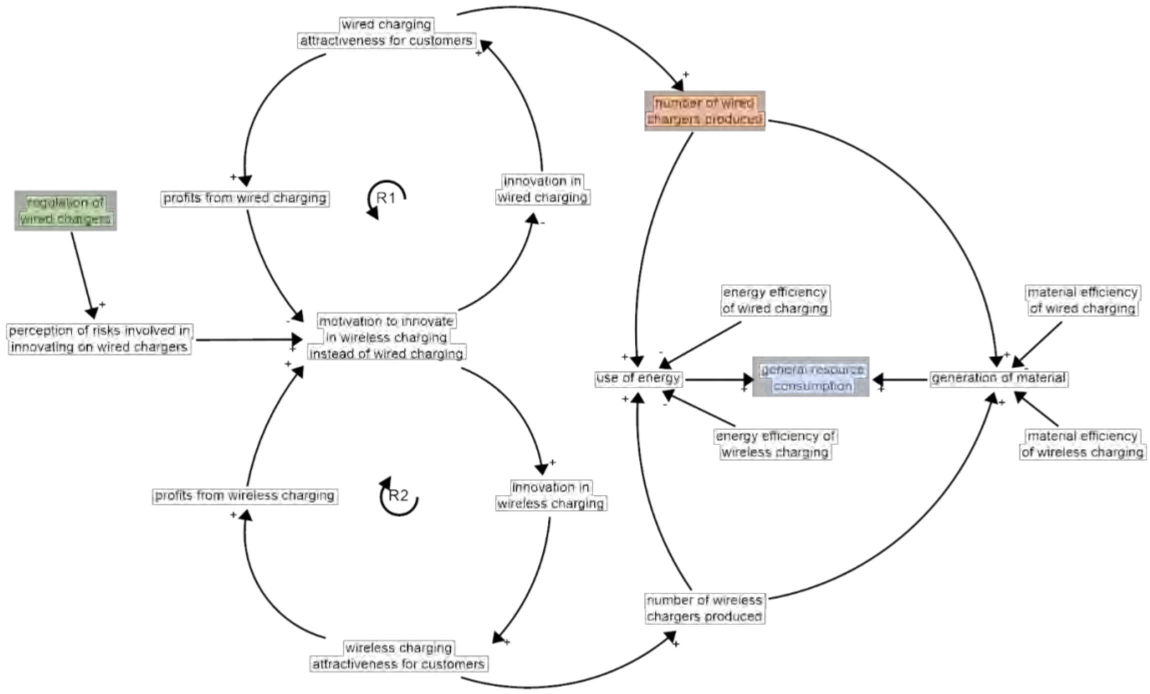

**Figure 3. Sub-model 3: CLD of the effects of measures in unlocking less regulated technologies.**

*technology and politics when it's most wonderful."* He further suggested that the context may have already shifted by the time a particular policy comes into play, rendering it less useful than it would have been in the past. Therefore, agility is critical in examining the applicability of the measures to new technologies so that unnecessary charging systems are not produced due to known reasons such as an obligation to purchase, multiple interfaces and protocols, and a short lifetime.

It is also critical to keep in mind that both technologies incur the *use of energy* and *material* resources. If the unregulated technology is less resource-efficient, this will cause additional impacts – hinting at the need to reach a more generic policy that avoids focusing on wired charging but on charging systems in general. Additionally, the capacity to unbalance the innovation dynamics should also be applied to accelerate the implementation of sustainability-oriented technology. In that manner, if a new stable technology proves more material and energy efficient, there could be measures to accelerate the change to a new common charger. In that case, the effects of resource use in transitioning to the new technology should be considered.

### *Sub-model 4: Ripple effects in the sector and other regions*

Figure 4 depicts the ripple effects of the initiative in the sector and other regions. The adoption of the common charger in Europe has the potential of positive ripple effects in the electronics sector and other regions. The more manufacturers *adapt their processes* and *business models* and *perceive the risks in not applying harmonised standards to other products*, the more they will *innovate in those other products following harmonised standards*, considering if there are enough *synergies of the regulation to other products*. Also, there are potential ripple effects in other regions. As *public pressure for sustainability outside the EU* mounts, manufacturers might be more willing to push harmonised standardisation if they have adapted their processes and business models. An informant highlighted the far-reaching advantages of the EU as a large, unified market. *"If this regulation gets implemented in the EU, it will become very difficult for other geographies to not to synergise with it"*. He additionally expressed that this is given the presence of large companies with a vested interest in maintaining consistency across geographies. The informant suggested that this

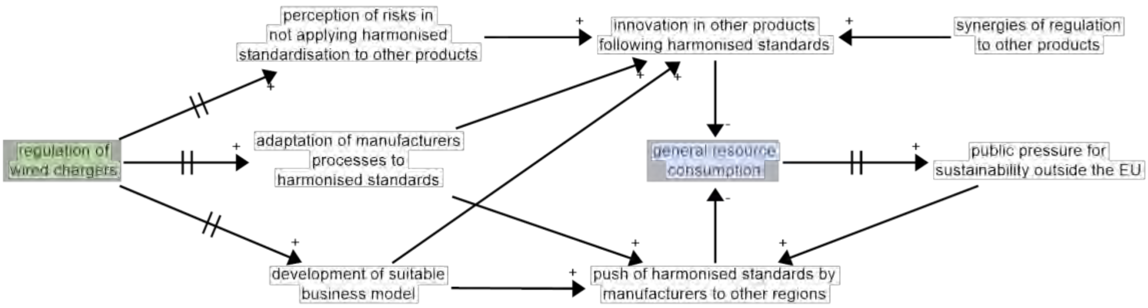

**Figure 4. Sub-model 4: CLD of the Ripple effects in the sector and other regions.**

regulation may have positive ripple effects beyond the EU's borders (Informant B).

*Consolidating and connecting the sub-models*

The four sub-models represent the system dynamics in different levels of abstraction and considering different degrees of feedback thinking. First, there is a higher level of detail in the intended consequences of regulating wired chargers (Figure 1) to a more abstract model of the ripple effects in the sector and other regions (Figure 4). Therefore, some of the reasons that cause the regulation to decrease the number of chargers produced are only available in sub-model 1. Meanwhile, the structure in sub-model 4 contains more hidden relationships and delays, which can be further elaborated if the intention is to understand the reasons and ways for ripple effects from the initiative.

Different degrees of feedback thinking are explicit by the detailing of relationships and the presence of feedback loops. While sub-models 1 and 4 lacked feedback loops, they still highlighted the relevant variables and interconnections that influence the system's behaviour, including multiple causal relationships. Meanwhile, sub-models 2 and 3 included reinforcing and balancing loops, providing a more in-depth knowledge of the structures that lead to counter-intuitive behaviour that might reinforce or counteract the initial intentions of the measures. Therefore, the four sub-models contribute to exploring the potential dynamics emerging from implementing the initiative.

The colour code used in the four sub-models makes the connection among them explicit through three key variables: *regulation of wired chargers*, *number of wired chargers produced*, and *general resource consumption*. The joint consideration of the sub-models enables a comprehensive examination of the intended consequences, unintended consequences, and mitigation strategies (Table 2). When simultaneously considering the four sub-models, it should be clear that replicating the initiative to other products may lead to similar potential RE and unintended consequences. Also, it is crucial to consider that regulating one technology will influence innovation in other

| Intended consequences | Unintended consequences | Mitigation strategies |
|---|---|---|
| • Reduced number of chargers per household<br>• Reduced obsolescence of chargers<br>• Reduced number of chargers produced<br>• Reduced general resource consumption<br>• Reduced generation of electronic waste | • Increased consumption of other products due to re-spending rebound mechanisms (R1, sub-model 2)<br>• Increased production of other products due to re-investment rebound mechanisms (R2, sub-model 2)<br>• Decreased motivation to engage in sustainability-oriented innovation (R3 and R4, sub-model 2)<br>• Unbalancing towards less regulated (and less sustainable) technologies (sub-model 3) | • Use additional profits for sustainability-oriented innovation (based on sub-model 2)<br>• Make the measures as generic as possible for charging (based on sub-model 3)<br>• Create mechanisms to facilitate adopting more sustainable charging systems when technology-ready (based on sub-model 3) |

**Table 2. Consequences and mitigation strategies for the common charger initiative.**

technologies, which can lead to additional resource consumption. Therefore, the common charger initiative is an opportunity to learn and resolve the RE, unintended consequences and other paradoxes that might emerge from implementing the harmonisation of standards in a product. Finally, the three identified mitigation strategies hints at ways of moving forward with the initiative while pushing it to other products, sectors and regions.

## Discussion and Final Remarks

This research aimed to investigate the use of qualitative SD to map the potential intended and unintended consequences of a policy initiative within the CEAP. Four interconnected CLD models made explicit the intended consequences of the common chargers initiative, as well as the RE and unintended consequences from the measures, how they can unlock less regulated technologies and the ripple effects in other sectors and regions.
Each sub-model detailed the dynamics of implementing the initiative alongside relevant informants' perspectives and recommendations from the analysis. This work puts into perspective several paradoxes of sustainability-oriented innovation, such as RE, unintended consequences, lock-ins, and ripple effects.
Breaking down the complex models into smaller, more manageable versions enhanced the readability and comprehension of the information presented, allowing readers to focus on specific aspects of the model without being overwhelmed by too much information at once. The research approach applied holds the potential to help uncover the intended and unintended consequences of other initiatives within the CEAP. The use of qualitative SD through CLDs can become an integral part of decision-making to provide a better understanding of the potential consequences of policy decisions and identify areas where unintended consequences might arise, working as the foundation for ex-ante analyses in the policy cycle (Janssen & Helbig, 2018; Weaver & Jordan, 2008). Also, the identification of mitigation strategies shows that the approach can assist in the development of policy mixes for sustainability transitions (Edmondson et al., 2019; Kliem et al., 2021; Rogge & Reichardt, 2016).

Meanwhile, the results of this research are substantially restricted by the examiners` mental models based on the information available. Follow-up research could use the CLDs in participatory discussions with citizens and decision-makers to assess their usefulness in public policy implementation. Also, there is space to unfold the CLDs into simulation models to create scenarios that can provide additional insight into policy implementation. There is plenty of opportunity for using qualitative modelling and simulation to assess and prevent adverse long-term effects of sustainability-oriented policies.

# Performance assessment tool for repair companies in terms of providing a service with the potential to increase demand for repairs

**Ines Güsser-Fachbach[a]**
a) University of Graz, Graz, Austria

**Keywords**: Repair; Repair company; Service operations; Recommended actions; Repair demand.

**Abstract**: For the transformation to a circular economy more repairs need to be carried out. In that context, ways to improve existing repair services need to be explored since the characteristics of a repair service may influence the decision of consumers between repairing or replacing their product. The research novelty of this short paper is the transformation of findings from literature and own research concerning the repair decision of consumers into a framework which consists of actual recommendations for repair companies to improve their service. Hence, the framework can be used as a basis to assess a repair company's performance in terms of increasing demand for repairs. In order to develop this framework, mainly qualitative and quantitative data were taken into consideration, which were empirically determined in Styria (Austria) in various prior studies. Also, insights from repair literature regarding topics of consumer behaviour and repair were taken into consideration to supplement the framework. The framework consists of four main categories (pre-service, accessibility, repair service, and post-service) and in every category there are on the one hand key tasks and on the other hand types of information which need to be provided by the repair company. The framework was evaluated by experts from the repair field, as well as from academia. Additionally, the research was complemented with the help of an online survey with repair companies in Styria, to investigate which tasks in the framework are already implemented in (Austrian) repair companies. All in all, the study contributes to research by tackling problems related to the optimization of services in the repair sector.

## Introduction

Recycling, refurbishing, remanufacturing, reusing, or repairing are essential return-flow-activities in a circular economy (Stahel 2016). Hence, for the transformation to a circular economy it is important to focus on companies undertaking return-flow activities, such as repair companies. Since there is a great number of users who do not repair their products (Sonego et al. 2022), ways to increase repair demand need to be identified. In this short paper the approach to increase demand by improving the repair service itself is considered since the characteristics of the service may influence the repair versus replacement decision of consumers. In particular, the fulfilment of customer expectations, in line with the expectancy-disconfirmation model of satisfaction (Oliver 1980), is essential. In that context, however, the question arises as to what measures repair companies need to take in order to offer a service that meets customers' expectations.

There is a growing number of studies regarding topics of consumer behaviour and repair in recent years, which analyse why users are (not) repairing their products. In that context for instance questions related to repair drivers and barriers (Laitala et al. 2021, Scott & Weaver 2014, Terzioğlu 2021), as well as customers' behaviours, perceptions, and profiles related with repair (Pérez-Belis et al. 2017, Rogers et al. 2021) were analysed. Also, common challenges repair technicians (Bovea et al. 2017) as well as consumers face while repairing products (Raihanian Mashhadi et al. 2016) were tackled in literature. Especially the repair decision of Styrian citizens (a state of Austria) was analysed in three scientific studies by the author in the course of a doctoral thesis (Fachbach et al. 2022, Güsser-Fachbach et al. 2023a,b). Based on the variety of findings in literature about the consumers' repair decision, the question is, what repair companies can learn from those insights, which is formulated in the research question of this short paper:

*Based on empirical insights about repair decisions of consumers, what are recommended actions for repair companies to increase repair demand?*

Hence, the research novelty of this short paper is the transformation of the findings from literature concerning influencing factors of the repair decision of consumers into actual recommendations/tasks for repair companies to improve their service. Moreover, to investigate the status quo, a quantitative online survey was distributed to repair companies in Graz (capital city of Styria) to identify what and how many of those identified tasks are already implemented in (Austrian) repair companies. There are three main contributions of this short paper: first, the framework can be used in literature as a basis for characterising main tasks related with repair service activities. Second, this study identifies where the greatest need for action exists in repair companies, which might be also an important information for policy makers aiming to promote repair. Finally, the developed framework can be used by repair companies to check if they have implemented all the listed requirements to increase the demand for repairs, i.e., the framework has direct implications for practice and can function as a performance assessment tool for repair companies.

## Methodology

### *Development of the framework*

In order to develop this framework with its recommended actions for repair service providers, mainly qualitative and quantitative data were taken into consideration, which were empirically determined in Styria in various scientific studies conducted prior to this study by the author in the course of a doctoral thesis (cf. Fachbach et al. 2022, Güsser-Fachbach et al. 2023a,b). All those studies focused on the same region/context and tackled the users' decision to use repair services and to what extent the characteristics of the repair service itself impact the decision. In addition, the data and findings of those studies were supplemented with other findings from the repair literature.

After the development of the framework, expert interviews were conducted to evaluate and improve the framework and its recommendations. During these interviews, first the framework was presented and second, experts were asked to critically review the framework and to make suggestions for improvement. In this context, two expert interviews were conducted with researchers from the repair sector and one interview with a person who is responsible for repair businesses in the municipality of Graz. The results of the interviews were considered in this study by using an iterative process: after every expert interview the suggestions for improvement of those experts were incorporated in the framework. Those suggestions were mainly related to individual tasks in the framework. The revised framework was then presented at the subsequent expert interview. All in all, the quality of the framework was rated as high.

### *Quantitative survey with repair companies*

To investigate the status quo in repair companies, a quantitative online survey was distributed in Graz between February 20 and March 2 2023 via the repair network of Graz (https://grazrepariert.at/) to ask repair companies to what extent the identified actions are already done in their repair company. In total 23 (small- and medium-sized) repair companies participated in the survey. Half of them are OEM-authorized repair companies and the other half are independent repair companies. The following types of repair companies participated: two, that repair bicycles, five that repair household appliances, seven that repair electronic devices, two that repair furniture, one that repairs garden appliances, two that repair shoes and bags, and four that repair clothes. Even though the sample is only a convenience sample, it is nevertheless possible to provide some initial insight into existing weaknesses of repair services based on the developed framework in this study.

## Framework

The framework (see Figure 1) consists of in total 37 tasks for repair companies, which all have an impact on the repair decision of users. 20 of those tasks specifically relate to the provision of easily available information, as the lack of information is a central barrier of existing repair services (Güsser-Fachbach et al. 2023a, Pérez-Belis et al. 2017, Sabbaghi et al. 2016).
All tasks are allocated to four categories, which combine tasks with the same content. The '*pre-service*' category consists of tasks which are related with the pre-purchase phase of the

service. Particularly aspects which are related to public relation efforts and trust-indicators are included. The second category is named '*accessibility*' as it consists of tasks which tackle the reachability of employees via various channels as well as the accessibility of the repair company. Tasks which are related with the service itself are allocated to the category '*repair service*'. Finally, there is a '*post-service*' category which consists of relevant tasks after the completion of the repair service. In the following all categories and its tasks are described in more detail.

### *Pre-service*

First, there is a necessity to highlight repair motivations related to environmental protection and social acceptance in public relations works of the repair company, as it was investigated in a prior scientific study by conducting a quantitative online survey with Styrian citizens (Fachbach et al. 2022). Environmental reasons as repair driver were also identified by Laitala et al. (2021) and Terzioğlu (2021) within their empirical repair study. Moreover, the economic motivation to repair should be highlighted by repair companies or other actors in the repair industry (Brusselaers et al. 2019, Fachbach et al. 2022). Especially since most often the repair costs are perceived as main repair barrier (Bovea et al. 2017, Scott & Weaver 2014), it is essential to emphasize in the course of public relation work the economic benefits to repair. The existence of repair funding can be a positive economic signal in that regard (Fachbach et al. 2022). Public relation efforts should also focus on repair reasons like sentimentality or nostalgia (Page, 2014), i.e., on the emotional attachment customers can have towards a product. Trust in the repair service providers (or trust that the repair company makes repairs of high quality) is also central for the repair decision (McCollough 2010, Rogers et al. 2021): relevant certifications (e.g., repair network membership), authorizations from the product manufacturer, or the appearance of the store may impact that trust (Fachbach et al. 2022, Güsser-Fachbach et al. 2023b). Also, positive reviews from former customers enhance the trust in repair service providers (Riisgaard et al. 2016). In a conjoint-study (another prior study in Styria), especially the importance of word-of-mouth communication was emphasized and the higher relevance of authorizations in comparison to repair network memberships (Güsser-Fachbach et al. 2023b). Public events which focus on repairs also raise awareness, provide information, and encourage word-of-mouth communication.

### *Accessibility*

Also the location of the repair store in terms of travel time of the customers to the repair store was identified to be important in two prior studies in Styria (cf. Güsser-Fachbach et al. 2023a,b), which highlights on the one hand the importance of strategic location decisions and on the other hand the necessity that there is a (large) offer of repair services also in rural areas (Fachbach et al. 2022, Gerner & Bryant 1980). Reachability of employees of the repair company through various communication channels (mail correspondence, telephone, or social media), long store hours, and alternative ways to bring the product to the repair company (e.g., by sending the products per mail) was additionally highlighted in the same study (Güsser-Fachbach et al. 2023a).

### *Repair services*

In a prior study it was emphasized by conducting focus group interviews and interactive workshops that an essential component of repair service convenience is information about repair services and specifically information about its affordability, i.e., repair service price (Güsser-Fachbach et al. 2023a). In that regard also factors which impact the repair service convenience during the repair service process (like loan devices, regularly updates during the repair service, cost estimates, or waiting time) were identified. Also, general consultation or advice from a direct contact person were highlighted, which is also a central component for high service quality in general (Parasuraman et al. 1985). Moreover, the waiting time is a central factor discussed in repair literature (Gerner and Bryant 1980, Wieser & Tröger 2018).

### *Post-service*

A guarantee for repairs was also determined to be relevant for increasing repair demand (Güsser-Fachbach et al. 2023b). Finally, since past repair experiences were identified to have a significant impact on future repair intentions (Fachbach et al. 2022, Laitala et al. 2021), in a variety of categories there are also indicators which are related to past repair experiences (e.g., vouchers which one receives after repair or encouraging online reviews of customers).

**Pre-service tasks**

- Advertising is being done (through google adwords, through social media, and/or newspaper ads).
- There is a discount for the first repair at the repair store.
- Repair company participates in public events which focus on repairs or related topics.
- The repair company is certified (authorized by the manufacturer of the product and/or a member of a repair network).
- Provide easily available information ...
  - ... about how much resources can be saved with repairs.
  - ... about the repair price versus the price of a new product.
  - ... about repair funding customers can apply for.
  - ... about how to apply for a repair funding (if a repair funding can be claimed).
  - ... about where to find previous reviews of customers about the repair service.
  - ... about certifications and authorizations of the repair company.
  - ... about which products are repaired with which types of defects.

**Accessibility tasks**

- The employees can be reached through various channels (mail correspondence, telephone, and/or social media).
- The store hours of the repair company are sufficient (late store hours and/or open on Saturday).
- Offer alternative ways to bring the product to the repair company (sending the products per mail, a box outside the repair company, and/or repairs carried out on site).
- Provide easily available information ...
  - ... about how employees can be contacted.
  - ... about where to find the repair company (also information about public transports).
  - ... about parking possibilities in front of the repair company.
  - ... about store hours.
  - ... about alternative ways to bring the product to the repair company.

**Repair service tasks**

- There is a direct contact person.
- Customers can get a loan device if needed.
- The waiting times are reasonable (waiting time for appointments, service on site, or repair) and the waiting time told to customers at the beginning of the repair is not exceeded in most cases.
- Regular updates are made during the repair (e.g. if the repair costs increase and/or if the repair is delayed).
- A cost estimate is provided and the price of the estimate, if the repair is carried out, will be deducted from the invoice at the end.
- The repair company offers different options for payment.
- Provide easily available information ...
  - ... about whether an appointment is needed for the repair.
  - ... about where the repair will take place.
  - ... about the type of defect and repairability of the product to be repaired.
  - ... about tips on the correct / gentle handling of a product.
  - ... about the expected duration of the repair.
  - ... about the repair price and its composition.
  - ... about how the customer is informed when the repair is finished.

**Post-service tasks**

- Customers have the opportunity to test the device after the repair.
- A solution is sought quickly if the defect reoccurs after the repair.
- A guarantee for the repaired part of the product is provided.
- Word-of-mouth-communication is supported (vouchers are provided which can be passed on to others and/or by asking customers to make google reviews).
- Provide easily available information ...
  - ... about guarantees for the repaired part of the product / about the procedure if the defect reoccurs after the repair.

**Figure 1. Framework for a performance assessment tool.**

## Status quo of repair services

By conducting a quantitative online survey, the status quo of repair services in Styria was investigated, by asking repair companies which of the recommended tasks of the framework (in Figure 1) they already do/have already implemented. There are a variety of tasks less than 60% of the surveyed repair companies already do: offering a loan device (57%), very late and/or very early opening hours (52%), participation in public repair events (43%), advertising through google adwords (30%), advertising through newspaper ads (30%), providing a discount for the first repair at the repair store (4%), and providing vouchers which can be passed on to others (4%). Regarding the provision of information, for the majority of information types customers get the information through a personal conversation with an employee. But only a smaller portion of the information is available on the repair company's website. No repair company or only one repair company answered that they inform about repair prices, the composition of the repair price, repair times, repair funding, or how much resources can be saved with repairs on their website. Moreover, on their website only 35% inform about parking possibilities, 30% inform about which products with which types of failure they repair, 30% inform about certifications and authorizations of their repair company, 26% inform about public stops nearby the company, 17% inform about where the repair takes place, and 13% provide information about whether an appointment is required for repair.

## Discussion

Based on repair company websites in Graz, the interactive workshops which were conducted in a prior scientific study (cf. Güsser-Fachbach et al. 2023a), and the online survey which was conducted in the course of this study, existing repair services have many possibilities to improve. Even if, mostly due to the size of the company, not all tasks can be fulfilled in the best possible way in a repair store, it can be assumed that fulfilling the majority of the proposed tasks will lead to an increase in demand, since all considered factors in the framework have been identified in prior studies as central to the repair decision-making process of users. All in all, if repair companies want to encourage more consumers to use their service, they can use the developed framework as guidance and as a performance assessment tool to fulfil that aim. Based on the conduced assessment in this study, repair companies need to focus especially on providing information about the service not only on a personal conversation but also on, for instance, their website, since information on websites can be more easily available. Especially since lack of information and the resulting uncertainty is a reason why users decide against repairs (Güsser-Fachbach et al. 2023a), this might impact demand. However, some types of information (like information about repair price or repair time) might be difficult to put on the repair company's website since due to the high amount of different failure types defining general price ranges might be too complex (Güsser-Fachbach et al. 2023a). On the other hand, at least the information about the composition of the price could reduce the lack of information regarding repair prices to a certain extent. There is also room for improvement regarding advertisements, since most surveyed repair companies in this study do not make any. This however, can also be due to the company size: Similar as most other European repair companies (cf. Eurostat 2019) the surveyed participants were small- and medium-sized companies with missing financial and personal resources to make a high number of advertisements.

## Conclusion

The study contributes to research as it tackles problems related to the optimization of services in the repair sector, which is a rather new research field. The study proposes a way of transferring insights from literature related with the decision-making process of consumers into recommendations of actions for companies. Hence, to derive strategies research which tries to understand why people do (not) do something is needed. Additionally, as repair services are discussed in the context of a circular economy, this short paper also highlights the importance of providing attractive services and products in the return flow in general, so that return flow activities can compete with forward flow activities (in terms of users' demand). Hence, future research should also focus on creating such frameworks for a performance assessment tool—based on insights about the users' decision-making process—for other companies in the return flow like companies acting in the area of remanufacturing or refurbishing. Regarding the developed repair framework, future (action) research can also test those tasks in practice at a variety of repair companies to determine on the one hand further improvement possibilities of the framework and on the other hand to identify the actual demand effect of the tasks in the framework.

# The Strategic Durability of Digital Product Passports: A New Perspective to Raise the Ambition

**Louise Møller Haase**[(a)], **Line Sand Lythje**[(a)], **Esben Bala Skouboe**[(a)], **Morten Lund Petersen**[(b)]
a) Aalborg University, Aalborg, Denmark
b) Fritz Hansen A/S, Denmark

**Keywords**: Digital Product Passport; Product longevity; Strategic Durability; Circular Economy.

**Abstract**: Digital product passports (DPP) are identified as a key element to contribute to the circular economy. DPP focuses primarily on the collection of product and material information from a manufacturing perspective all the way throughout the supply chain and is planned to be implemented through policy development toward 2030. However, we argue that if we unfold the strategic potential of DPP to make it more attractive to companies, we can speed up this implementation. Accordingly, this paper goes beyond the environmental benefits of DPP by proposing a conceptual framework for DPP services that can increase the product's value both from a user, market and company perspective. Through the concept of strategic durability, the paper contributes with a new perspective on DPPs, namely how companies through digital passport services can: 1) strengthen relationships to customers, 2) sustain and accentuate the company's values and competencies, and 3) generate long-lasting competitive advantage in the market. Finally, the paper qualifies the new concept for digital passport services based on a company case (Fritz Hansen A/S) to exemplify what this conceptualization will mean in the furniture industry.

## Introduction

Digital product passports (DPP) are identified as a key element to contribute to the circular economy (Adisorn et al., 2021) particularly pushed by policy development at the level of the European Union (EU) as part of the European Green Deal (European Commission, 2019) and the Circular Economy Action Plan (European Commission, 2020). Here DPP is identified as new means of gathering product and material information as a vital step for an effective circular approach. The aim is to provide all involved actors to have a better understanding of a product's composition, the environmental impact of the production and use phase, and the recycling options at the end of the product lifecycle (Plociennik et al., 2022), and thereby improve products' durability, reusability and repairability.

The implementation of DPP is currently discussed on a policy level and relies on policy action and regulations which means that the implementation process may happen relatively slow (Walden et al., 2021; Plociennik et al., 2022) and an applicable and holistic DPP approach is still being determined (Adisorn et al., 2021). Moreover, there are still ongoing discussions about the degree of required information to achieve circularity (see e.g. Eppinger et al., 2021; Walden et al., 2021).

Some of the legal requirements for DPP is that manufacturers provide comprehensive information about a product's traceability, repair and dismantling options as well recycling guidelines. At the current state, the concept of the DPP focuses primarily on the collection of product and material information from a manufacturing perspective all the way throughout the supply chain and it will be implemented through policy development. As such, the current focus is on the products' physical properties that will increase the closing and slowing of resource loops.

However, in line with Plociennik et al. (2022), we argue that other type of information is equally important to the circular economy, especially for slowing down the resource loop, namely information that will also strengthen the strategic durability of a product. For instance, it is not enough that the product itself is repairable if the user for some reason does not want to repair it. Likewise, the repairable act should also make sense to the company in a way that is strategically beneficial in the long term.

Finally, the DPP could also have some strategic benefits in regard to a company's market positioning. Such user, market and company perspectives are highly overlooked in current discussions on DPP.

In this conceptual paper, we unfold the potential of DPP beyond the environmental benefits by proposing a conceptual framework for DPP services, that can support the development of the DPP from a company, market and user perspective with the intention of speeding up the implementation of DPPs. The research question explored in this paper is following: *How can we make the concept of DPP strategically relevant to companies and thereby speeding up the implementation process?*

Accordingly, with a strategic view on DPP, this paper contributes with a new perspective on DPPs, namely how companies through digital passport services can strengthen a product's strategic durability and thereby increase the product value in regard to both users, market positioning and the company.

This new perspective on DPP intends to make its implementation more attractive for companies (and not only a legal requirement that concerns a product's physical aspects) thus speeding up the implementation process. Finally, the paper aims to qualify the new concept for digital passport services based on a case company, Fritz Hansen A/S, to exemplify what this conceptualization will mean in the furniture industry.

This paper is structured as follows: First, we review the concept and framework of strategic durability that is a central aspect of designing products with high longevity. Then we conceptualize the DPP in respect to strategic durability, specifying how a DPP can support a product's strategic durability and thus increase value in respect to user, market and the company perspectives, supported by an example from the furniture industry.
Finally, we discuss how the strategic perspective on DPP is also relevant for other industries and suggest possible future research avenues to be explored.

## Strategic durability

In this paper, we propose that DPP can be seen as an integrated part of a long-lasting product's value proposition. To achieve this, we suggest the framework of strategic durability (Haase and Laursen 2022) as a starting point to further develop the concept of DPP and to add this new perspectives on the strategic potential of DPP for products with high longevity.

If we look at current studies on circular economy, the majority of circular strategies focus on the technical, functional and material aspects of products to close or slow down resource cycles (Lofthouse and Prendeville, 2017). While these strategies are vital steps to achieve sustainability, there are additional aspects that are equally important but highly overlooked in current research; that is the competitive and strategic aspects of products that also have a vital influence on a product's lifetime. These aspects are addressed in terms of 'strategic durability' (Haase and Laursen, 2022).

In their book, Haase and Laursen (2022) describe strategically durable products as products that have long-lasting strategic fits to both the user, the market and the company. This means that a product must both fulfill long-term user needs, create long-term competitive advantage in the market and be strategically relevant to the company in the long term (see Figure 1).

This framework is highly relevant to unfold and understand the competitive and strategic potential of DPP as well; a focus that is highly overlooked but could be an important parameter for companies. In such case, the implementation of DPP would then be perceived as an attractive tool for companies to escape trap of greenwashing because it shows and documents the company's efforts, thus the DPP becomes attractive to companies to enhance the strategic durability of their products. Accordingly, the implementation process could also be pushed by companies, which would speed up the implementation process.

In the following section, we propose a conceptual framework that describes what strategic durability would mean in the context of DPP.

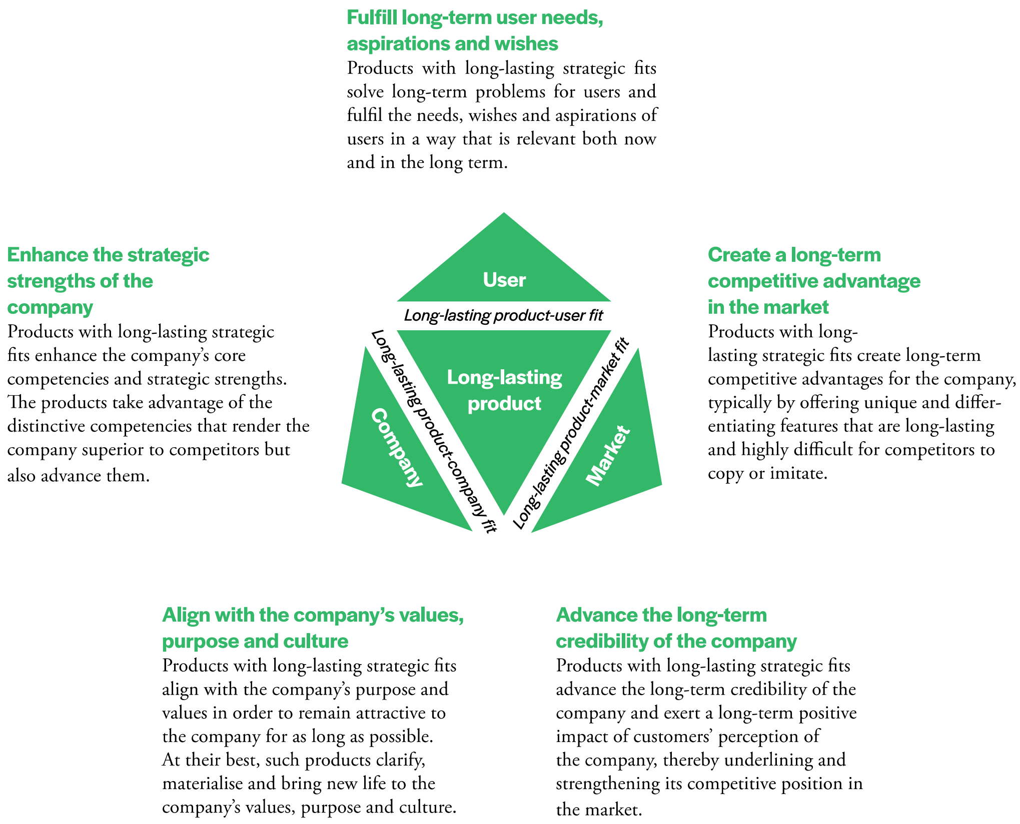

**Figure 1. A product with strategic durability has long-lasting strategic fits to the user, the market and the company (Haase and Laursen, 2022).**

## The new DPP service: supporting the strategic durability of products with high longevity

Based on the framework for strategic durability, we created a conceptual model for how DPP can serve as an aid to support the longevity of products and thus become an integrated part of a product's long-term value proposition. The following describes the general model for how companies can increase the product value from a user, market and company perspective (summarized in Figure 2).

*Increased value in respect to the user*

First of all, the new DPP service must support the product in fulfilling long-term user needs, aspirations and wishes.

To accomplish this, the DPP must include unique features to the product that becomes an important part of the product's value proposition. For instance, the DPP could include information about the product's unique story that supports or increases the longevity value of the product (see the Fritz Hansen case for an example).

*Increased value in respect to the market*

Secondly, the new DPP service must support the product in creating long-term competitive advantage in the market and advance the long-term credibility of the company.

This means that the DPP should include differentiating features that would be difficult for competitors to copy and affect the customers' perception of the company in a positive and sustainable direction (see the Fritz Hansen case for an example).

*Increased value in respect to the company*

Finally, the new DPP must support the enhancement of the company's strategic strengths and competencies, and align with the company's long-term core values, purpose and culture.

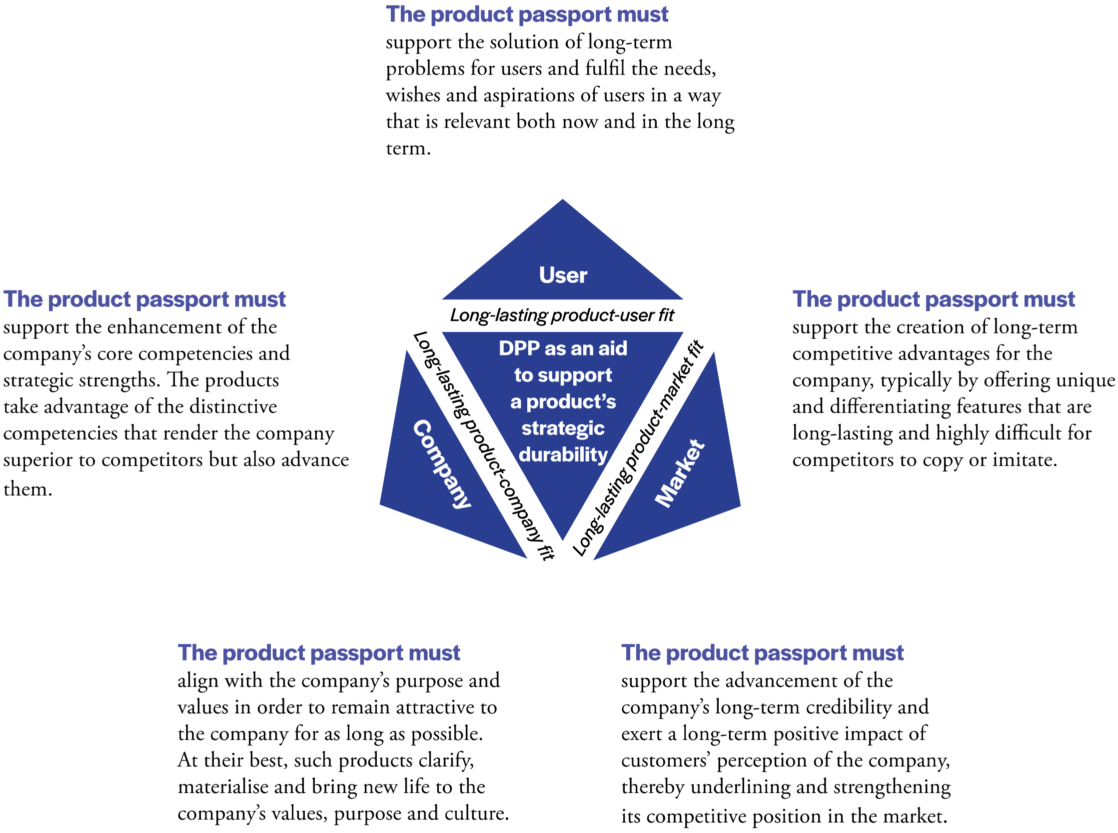

**Figure 2. Conceptual model for DPP as an aid to support a product's strategic durability.**

This means that internal processes in the company (such as production or specific technologies) needs to be long-term relevant for the company to sustain and enhance the credibility and longevity value in the company (see the Fritz Hansen case for an example).

## The strategic potential of the new DPP in the furniture industry: the case of Fritz Hansen

This section unfolds the new conceptualization with examples from the case-company Fritz Hansen A/S (summarized in Figure 3).

Fritz Hansen A/S is a well-known Danish company producing high-end luxury furniture, lighting and home accessories designed by Danish and international designers. The company has a long and rich history of crafting iconic and lasting products such as Arne Jacobsen's Egg, Swan and Series 7 chairs. Core values are premium quality, expert craftmanship and high-end materials. Fritz Hansen has made different initiatives to keep their products alive for as long as possible, such as refurbishment programs and takeback systems. Some products in their refurbishment process are more than 50 years which proves the longevity of their products.

Fritz Hansen A/S has been involved in an ongoing research process where we discussed the possibility of how a DPP could support their products and business with specific focus on the longevity challenge. The work is based on a close collaboration between the management teams in the company (strategic business development, CSR and product development respectively) and researchers in the field in a period of one year. This resulted in data based on presentations, a research application, visits and meetings during this collaborative process.

### *Ownership documentation (user value)*

In the specific case of Fritz Hansen, one of the long-term problems that were identified from a

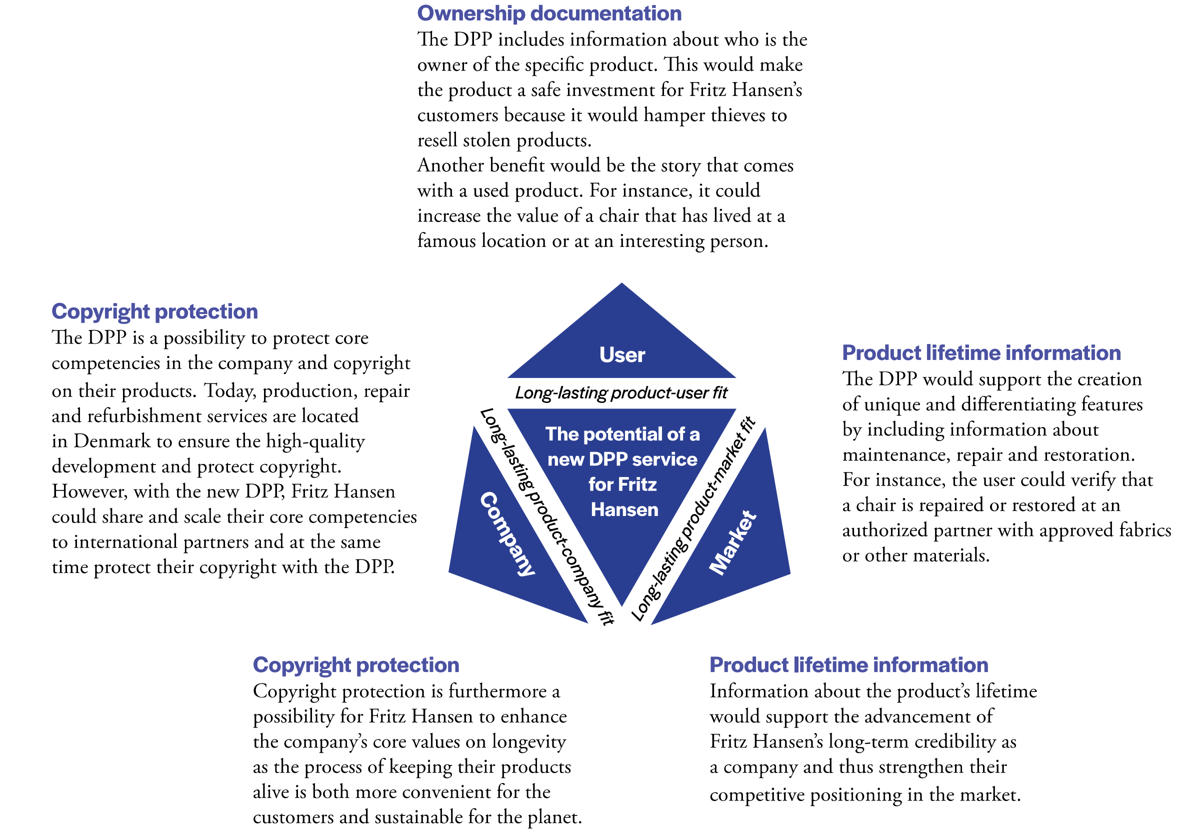

**Figure 3. The strategic potential of the new DPP service in the case of Fritz Hansen.**

user perspective was the risk of having the products stolen. In such case, a main benefit of the DPP could be "ownership documentation" that is information about who is the owner of that specific product. This would make a Fritz Hansen product a safe investment for their customers because it would hamper thieves to resell stolen products.

Another benefit of an "ownership documentation" would be the story that comes with an older used product. For instance, it could increase the value of a chair that has lived at a famous location or at an interesting person.

### *Product lifetime information (market value)*

Besides ownership documentation, Fritz Hansen also sees the potential that the DPP can support the creation of unique and differentiating features by including information about maintenance, repair and restoration. For instance, the user could verify that a chair is maintained, repaired or restored at an authorized partner with approved fabrics or other materials, just like a service manual for a car that includes information about previous owners' caring. This will also serve as a tool for secondhand sale at auctions to proof validity and track product history.

Information about the product's lifetime would furthermore support the advancement of Fritz Hansen's long-term credibility as a company and thus strengthen their competitive positioning in the market.

### *Copyright protection (company value)*

Finally, the DPP is a possibility for Fritz Hansen to protect their core competencies in the company and copyright on their products.

Today, production, repair and refurbishment services are located in Denmark and Poland to ensure the high-quality development and to protect their copyright. This means that if products are to be repaired or restored, they need to be shipped to Denmark which is neither a sustainable solution nor a convenient solution for the customer. However, the current challenge for Fritz Hansen is that if their core competencies are shared, there is a risk that products easily get copied. But with the new DPP, the company could actually share and scale their core competencies to international partners and at the same time protect copyright on their products with the DPP.

This initiative is furthermore a possibility for Fritz Hansen to enhance the company's core values on longevity as the process of keeping their products alive is both more convenient for the customers and sustainable for the planet.

## Discussion and conclusion

In this paper, the aim was to explore the strategic potential of DPP to make implementation attractive to companies and thus speed up the implementation process.

Based on the framework of strategic durability, we conceptualized the DPP as an integrated part of a product's value proposition in respect to both the user, the market and the company. This conceptualization was concretized with an industry example based on close collaboration with the furniture company Fritz Hansen A/S.

### *Implications for research*

This paper has contributed with a new perspective on the DPP that is relevant in the context of products with high longevity to strengthen their strategic durability. However, this research is still initial and conceptual which means that more research is needed to qualify its potential in a broader perspective and other industries. Accordingly, we suggest a number of research avenues to be addressed in future studies:

First, it would be interesting to explore how companies can work with the strategically durable product passport in practice and in different contexts. This would require an experimental approach in order to detail and qualify the framework for application in practice. Second, there is an ongoing discussion on how to communicate information to a multitude of stakeholders in a product's lifecycle (users, manufacturers, recyclers, etc.) and on which platform to access information (Plociennik et al., 2022). This is still a topic that needs investigation.

Finally, with this new perspective on DPP there is a need to investigate how the strategic aspects addressed in this paper would meet the policy requirements in practice in DPP.

### *Implications for practice*

This paper illustrated how the new DPP service would support and enhance Fritz Hansen's sustainable business model.

In particular, the company showed a very positive attitude to the new concept because it could work as a central means to solve some of the strategic challenges in a circular economy context but also to enhance their sustainable profile with differentiating features in their products. This work has now resulted in an implementation process at the company.

While the abovementioned example shows a great potential of the new DPP in the furniture industry, the strategic perspective on DPP would be highly relevant for other industries as well where products with high longevity are a central part of a company's business model. We hope that this work would inspire other companies and industries to find the strategic benefits of the DPP that could increase value for the users, the market and the company (and not only the environmental benefits driven by policy development) to make implementation of DPP attractive and meaningful in practice.

## Acknowledgments

The authors thank the people from Fritz Hansen A/S for the collaboration, interest and the valuable insights in the process of conceptualizing the digital product passport service.

b) Clarasys, London, UK

**Keywords**: Customer experience; Circular business models; Design tools; Customer journey mapping; Design thinking.

**Abstract**: Customers are key stakeholders that contribute to the flow of products and materials in the circular economy through their behaviours, e.g., repairing, reusing, renting, refilling and recycling. Customer experience can either drive or hinder adoption of these behaviours. However, currently the understanding of customer experiences when performing these behaviours remains limited, yet important to consider when designing circular offerings. This study seeks to: 1) understand what the key aspects of customer experience are when enabling the circular flow of resources, and 2) provide tools that consider consumer experiences into circular offerings. A literature review, two round table discussions and twelve interviews with industry experts were conducted to provide the basis for the development of a 'CE/CX Toolkit' which is a collection of tools developed to aid industry practitioners to design circular offerings that better account for customer experience. This paper presents one of the tools, namely the 'The Circular Journey Design Framework' which specifically uses consumption work as well as the capability, opportunity and motivation framework (COM-B) to define and target consumer experiences in circular offerings.

## Introduction

Customers, both B2C and B2B, are vital actors for enabling product and material flows in a circular economy (CE) (Mostaghel & Chirumalla, 2021; Kahraman & Kazançoglu, 2019; Wastling, Charnley & Moreno, 2018). Yet, only around 10% of current peer-reviewed published research on CE focus on "consumers", "consumption" and "users" (Camacho-Otero, Boks & Pettersen, 2018). Furthermore, within industrial contexts, customer experience of circular offerings (i.e., products and services operating on the market to facilitate CE) is only starting to be understood, as there has been a greater focus on feasibility and viability factors when designing circular business models (CBMs) (Haines-Gadd, Bakker & Charnley, 2023).

Customer behaviour and active engagement with circular offerings are crucial for the successful implementation of a CE system (Mostaghel & Chirumalla, 2021). Thus, with customer experience being a key determinant of the level of their engagement, it is important this is understood and addressed at the design stage of circular business models to increase the possibility of adoption. This study aims to identify 1) what are the key customer experience factors that businesses should address in the design of circular offerings and 2) what design tools can enable businesses to create circular offerings that target customer experiences to meet their needs, desires and expectations and subsequently drive the uptake of circular behaviours.

## Literature Review

A review of current literature was conducted to identify how the research community positions the customer experience in the context of CE. Scopus and Google Scholar online databases were used to find relevant literature through a keyword search of combined phrases, specifically "consumer" or "customer" or "users" or "consumption" AND "experience" AND "circular economy" or "circular business models". As a result, 58 of articles were found and reviewed.

### *Customer experience and circularity*

Customer experience is defined as a multidimensional cognitive, emotional, behavioural, sensorial and social response of customers to their interaction with an offering on the market. Customer interactions with an offering are analysed across all phases of the experience including those before and after consumption allowing for an end-to-end perspective of the journey of the customer (Lemon & Verhoef, 2016). Understanding this is crucial for developing comprehensive circular business model design due to complexities associated with designs of circular systems (Muranko et al., 2021; Ta, Aarikka-Stenroos & Litovuvo, 2022).

The literature review revealed, that much of the published research can be differentiated based on their thematic focus on various 1) industrial sectors (including fashion, electronics, FMCGs), or 2) product categories (e.g., mobiles, hoovers, refillable packaging) or circular business models (e.g., refill, refurbishment, repair, PSS). This broad thematic focus poses a challenge to generalising approaches on what is the best practice when designing customer experiences into the circular offerings. Moreover, the different levels of visibility and publicity of certain products (hoover vs mobile phone) imply that adjustments to service offerings ought to be made for different product categories (Boyer et al., 2021).

However, the current literature has a greater emphasis on the psychological determinants of the customer behaviour, with a growing knowledge on attitudes, acceptance and perception towards circular business models and practices (European Commission, 2018; Boyer, Hunka & Whalen, 2021; Mantelatto Pecorari & Camello Lima, 2021; Camacho-Otero, Boks & Pettersen, 2019; Elzinga et al., 2020). Similarly, for tools and methods, there has been increasing research using or developing approaches to mapping customer journeys in CE (Selvefors & Rexfelt, 2019; Sinclair et al., 2018; Nielsen, 2019; Zeeuw van der Laan & Aurisicchio, 2019; Muranko et al., 2021). Nonetheless, the review identified a set of overarching research themes related to customer experience, including 1) new roles, 2) new behaviours and habits, and 3) new relationships. Customer experience, due to it playing a key function in influencing the psychological determinants of a behaviour, is seen as highly relevant in driving the customers to adopt these new roles, new behaviours and relationships required for the CE to be practiced at scale.

### *New customer role in CE*

There are novel functions and responsibilities required of customers in circular offerings (Mont & Heiskanen, 2015). To participate in the circular offering, customers can no longer be the *"passive recipients of goods and services on the market"* (Weiser, 2019), and instead are the active facilitators (e.g., co-producers) of the circular value chain processes through the performance of circular behaviours such as, maintenance, recovery and circulation of materials, components and products in the economy (Mont & Heiskanen, 2015; Zeeuw van der Laan & Aurisicchio, 2019; Muranko et al., 2020).

Consumption work is a term used to describe the additional labour or effort required of the customer when acquiring, using, re-using and disposing of goods, and is a useful concept for providing insights on the customer experience of circular offerings (Hobson et al., 2021). For example, specific circular business models can involve an increase of domestic novel recycling behaviours or the learning of new skills to maintain, repair and share products. Therefore, it is pertinent for companies to consider the capabilities of individuals and households to perform these tasks, what resources are required (time, money, social capital) and whether there may be an unbalanced gender division of this additional work (Hobson et al., 2021).

### *New customer behaviour in CE*

Engagement with circular offerings requires the customer to perform new behaviours such as renting, refilling, repairing and returning products for recovery (Chamberlain, 2020; Muranko et al., 2021). Understanding how these behaviours unfold in the customer journey is necessary to inform the design of circular offerings.

### *Circular behaviour chain*

Behaviour chains are a series of unique actions performed sequentially until the end-goal of the behaviour chain in a circular offering is achieved (Muranko et al., 2020). Within behaviour chains there are 'forking' paths which represent a moment in a journey of the customer when they are faced with a choice to perform one of several possible actions which ultimately influences whether they are enabling the circular flow of resources in the system (Muranko et al., 2020). For example, in a reuse offering, a customer can choose between two options, either to return their container to the provider via a drop-off location for recovery, or dispose of it at kerbside into a waste stream (Muranko et al., 2021). The former choice ensures the resources, (i.e the reusable packaging) can flow onto the next customer for reuse, whereas the latter choice sends the container to landfill, effectively ending its life. In the context of this project, we use the forking paths to define what are the ***'key moments of circularity'*** i.e., stages of customer journey where they make a decision whether or not to engage with circular offering determined by their subsequent behaviours.

### *COM-B Framework*

The COM-B model of human behaviour change posits there are three key factors – capability, opportunity, and motivation – essential for a behaviour to occur (Michie et al., 2015). The COM-B model helps identify what needs to change in order for particular behaviours to be carried out. It also acts as a framework to determine what type of pain point an actor may be encountering, in order to determine what type of intervention should be administered to enable the desired behaviour.

In many circular customer journeys, actors are required to perform behaviours that are different from linear journeys (Chamberlain, 2020). The COM-B model can be used to identify the gap between linear and circular behaviours, and help pinpoint what behavioural factors need to be addressed. For example, a customer may be interested in saving money (motivated) and have access to the necessary tools (opportunity) to perform a repair, but they may lack the knowledge (psychological capability) to carry out the repair. This insight helps to determine where to focus a behaviour change intervention.

### *New relationships*

As a result of new roles and new behaviours performed by customers, ultimately new relationships will be formed between customers, products and organisations through the engagement of circular offerings (Haines-Gadd, Le Fouest, Maguire, & Salter, 2022). Through the process of 'value co-creation' (i.e. maintaining and recirculating of goods) by both customers and producers a stronger and more dynamic relationship can be formed (Re & Magnani, 2022), moving from one-transactions to long term relational engagements (Schallehn et al., 2019).

## Methodology

The CE/CX toolkit was developed using insights from the review and two round table discussions with 10 participants and twelve semi-structured interviews, all conducted with industry practitioners from low-involvement (e.g., FMCGs) and high-involvement (e.g., electrical domestic appliances) product sectors, who are seeking to or are in the early stages designing and implementing circular offerings. Data was gathered from industrial participants to uncover both best practice and limitations within the process currently being employed. These participants were also chosen to ensure the research outputs would be practical and applicable within an industrial context.

| Method | Description | Output |
|---|---|---|
| Roundtable discussion 1 (10 participants) | Online session facilitated using Miro (2h in duration) | Present key concepts found in the review to gather feedback and applicability |
| Semi-structured interviews with experts (12 participants) | Online recorded interview (1h in duration each) | Gain insight on challenges, limitations and best of practice of current CE/CX process |
| Roundtable discussion 2 (10 participants) | 2hr online session facilitated using Miro (2h in duration) | Test draft tools and validate outcomes of interviews |

**Table 1. Summary of methods for research.**

## Results

In response to the data gathered, a CE/CX toolkit was developed that assists organisations to better consider the perspective of customers when developing circular products and services.

To construct the tools, existing design thinking and customer experience methods were reviewed and used as a foundation and inspiration. It was determined that while several new tools needed to be created, providing a circular lens to existing approaches would also be sufficient.

The toolkit consists of three main sections:
**1. Exploring Circular Value** - uncovering who your customers are, what value CBMs might provide to your customers, imagining new circular journeys and how to conduct user research.
**2. Designing Circular Services** - circular customer journey design, behaviour change pain point analysis, behaviour change ideation, solution prioritisation, circular service blueprints.
**3. Delivering Circular Value** - CBM pilot definition, CBM pilot agile governance, CBM pilot measurement framework.

The aim of the three sections is to provide suggestions and tools to companies at different stages of their circular development journeys, so that this toolkit can provide value to companies very early in their explorations as well as those more advanced in the circular implementation.

A link the full toolkit can be found here: https://www.clarasys.com/creating-customer-experiences-in-a-circular-economy-toolkit/?utm_source=merryn-exeter&utm_medium=plate-conference-paper&utm_campaign=cx-ce&utm_content=creating-customer-experiences-in-a-circular-economy-toolkit

Considering the breadth of the toolkit it was decided to present just one tool in detail 'The Circular Journey Design Framework' as this tool combines the key concepts uncovered from the literature review and is a central activity of the toolkit.

## The Circular Journey Design Framework

This tool contains two main steps, customer journey mapping and COM-B pain point analysis.

*Step one - Circular journey mapping*

Map both the current linear journey of the customer and the to-be circular journey identifying and reflecting on the following key concepts for circular journeys:

- **Key Moments of Circularity** - points within the journey that impact the circularity of product.
- **Key Moments of Circular Effort** - tasks or actions that might require an increased relative effort (physical, mental or emotional) or additional steps compared to the as-is linear journey.
- **Key Moments of Circular Delight** - the touch points that have the biggest potential "value", "reward" or "fulfilment" for a persona.

It was decided to map the linear journey in parallel with the to-be circular journey to demonstrate the significant differences between the two journeys, highlighting key pain points that might require intervention. To demonstrate this tool in action, an example of a company who provides refillable beverage kegs in supermarkets is shown in figure 1.

Comparing the two journeys, at the acquisition and transfer stage there is an increase in the number of tasks the customer must perform, as well an increase in relative effort. Filling the keg and returning the keg to the store are also the two moments that impact the circularity of the product and service, therefore these are the key moments of the journey that will require intervention.

**Step 2 - COM-B pain point analysis**

Using the list from step 1 of the key moments of the journey that require intervention, perform a COM-B analysis on these pain points and uncover in detail the drivers which will influence this behaviour that needs to be performed.

Looking at figure 2, at the two stages that are most crucial to circularity and effort, i.e filling keg and returning keg phase, COM-B pain point reveals:

**Filling keg:**
- Capability factor - the user doesn't know how to fill it
- Motivation issue - perception that quality of the product will be lower

**Returning Keg:**
- Motivation factor - must plan ahead and remember to bring it
- Opportunity factor - usually shops directly from work so needs to take to work

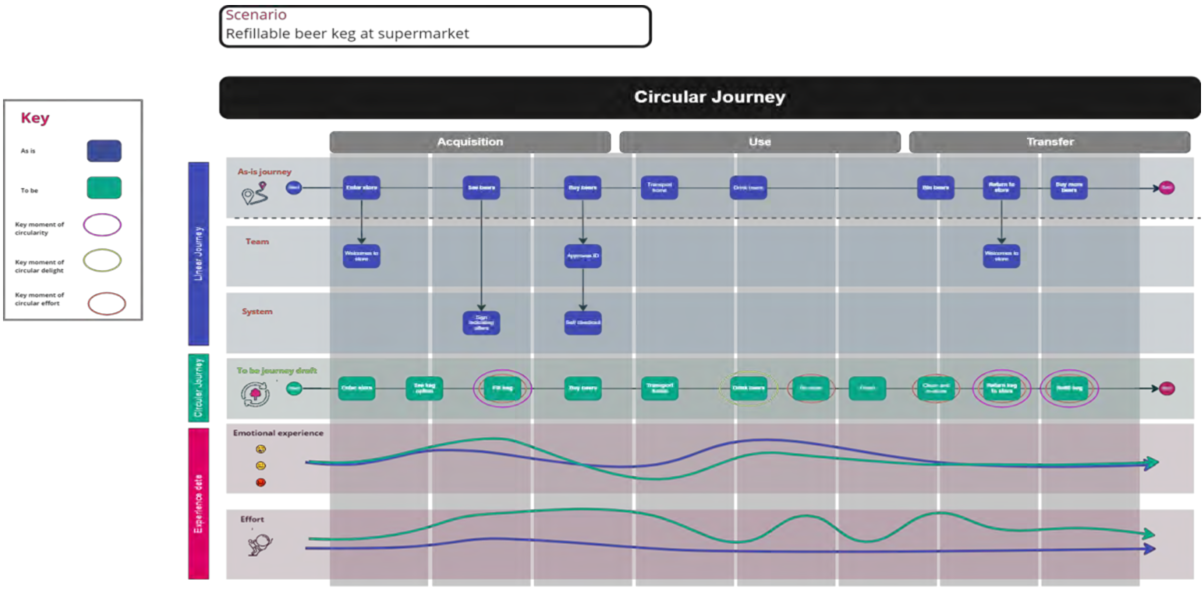

**Figure 1. Customer journey for a circular offering.**

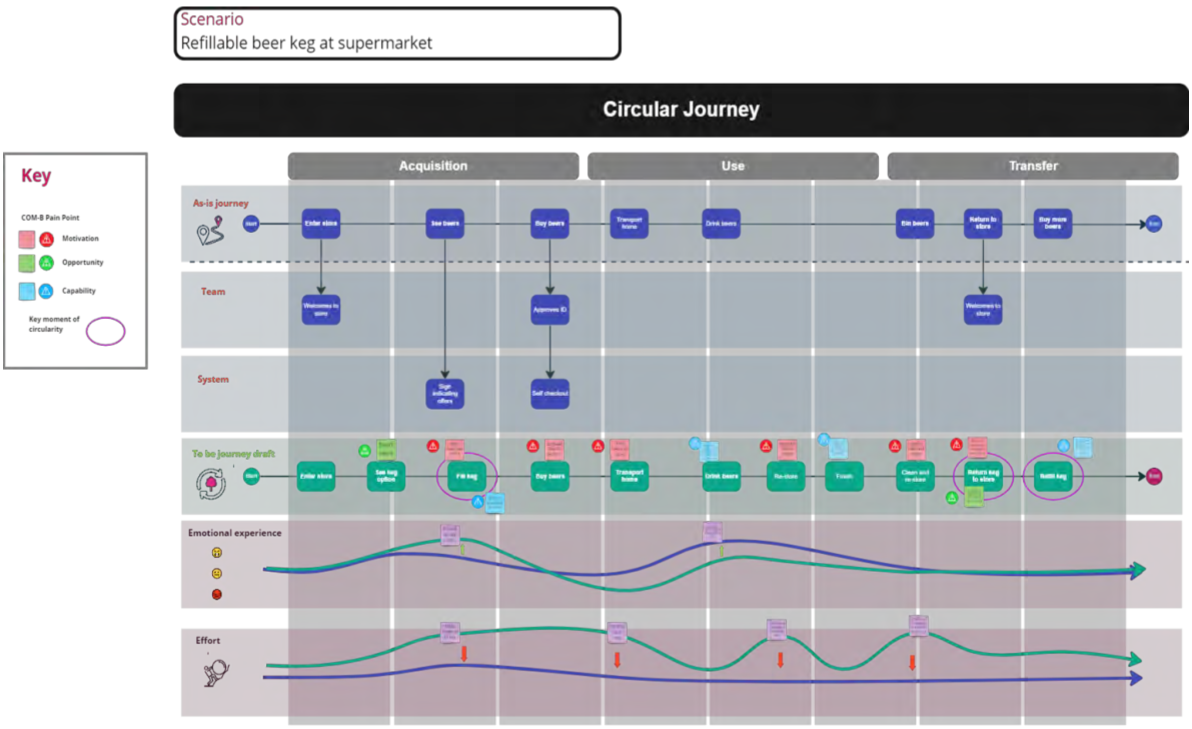

**Figure 2. Circular customer journey with COM-B pain point analysis.**

In summary, the key outcomes of this tool and process is a clearer picture of the relative effort of the journey, key moments of circularity and an in-depth understanding of factors that influence the behaviours performed. This tool brings together thinking from both the COM-B framework and consumption work theories making them easy to understand and accessible to user experience and sustainability practitioners. The other tools and methods in the CE/CX toolkit are designed to produce similar outputs so that industry professionals can better account for customer experience when designing and delivering circular business models in practice.

## Discussion and Conclusion

A central premise of this study is that meaningfully considering customer experience when designing circular offerings is vital to ensure the widespread adoption of CE products and services. This was observed through the interviews with industry experts, as those more advanced and successful in the implementation of circular offerings had performed detailed explorations into the experience of their customers for their current linear and to-be circular journeys with some having circular offerings already on the market. However, it is important to note that accounting for experience or ‘desirability’ is only one factor of circular business model design; there are infrastructure/system challenges that need to be designed for as well.

Circular offerings are more likely to have increased complexity than linear offerings and tend to involve more stakeholders (third party actors such as reverse logistics providers) and increased technology touch points (apps, reverse vending machines), which will also require careful design consideration.

It is anticipated that this toolkit will be a useful guide and prompt to both user experience and sustainability practitioners and was designed to bridge the gap between these two disciplines. The approach fuses thinking from both practices aiming to enhance capabilities and awareness in both spaces.

*Limitations*

The scope of the study is focused on the customer, i.e. B2C circular products and services, however could be used to consider B2B2C scenarios as well. The tools have only been tested with participants from FMCG and customer goods sector.

*Further research*

The toolkit should be tested within other sectors such as fashion and transport. It was designed to be open source and free for both academics and practitioners to use and adapt.

## Acknowledgements

We want to thank the industry participants for their time to make the study possible; the wider Clarasys team for helping conduct interviews and test tools, in particular Nicky Croxford for getting the work to a wider audience. And lastly, the academic researchers who shared their work with us to help shape our thinking.

# Learning Circular Design from within the Fashion Industry: A ReSuit project case study

**Cathryn Anneka Hall[a], Karen Marie Hasling[a], Ulla Ræbild [a]**
a) Design School Kolding, Kolding, Denmark

**Keywords**: Circular design; Fashion; Design guidelines; Industry designers.

**Abstract**: This paper explores the circular design tools industry-based fashion designers require to transition from linear to circular practices. This research was conducted as part of the research. Project, ReSuit (Recycling Technologies and Sustainable Textile Product Design) together with industry partner and fashion company Bestseller. This research began with the publication of Bestseller's 'Circular Design Guidelines' (CDG), developed to communicate circular design for the designers working in their various brands. This paper expands this area of research by exploring the needs of brands that are not traditionally associated with sustainable fashion and specifically addressing how a design tool can aid their progress. Data was collected through presentations and online interviews with members of the design teams that actively used the guidelines and was analysed using an annotated portfolio method to draw out connections and relationships. The results show that the designers who used the CDG were able to make space and time to engage deeply with the design strategies; asked questions of their suppliers they wouldn't normally; as well as provide inspiration to create circular products. The paper concludes that although the use stage was an entry point for many of the design teams, where they creatively implemented strategies for longevity from their desks, beyond this there was significantly less engagement to understand user preferences for increased garment use. This paper suggests that industry designers would benefit from additional methods or tools to help them understand how to engage with their users and apply this knowledge to their design towards garment longevity.

## Introduction

While the world of academia pushes forward its vision for a transition from linear to circular design practices, the fashion/textile industry lags behind in implementing this (Karell & Niinimäki, 2020). This is not due to a lack of commitment, as Global Fashion Agenda (GFA) reported in 2019, 87 targets (41% of the total made) were set down by brands to implement design strategies for cyclability by 2020. However, only 24 of these targets were reached. While their ambitions on a top level were admiral, focusing on training their employees in circular design, this presented many challenges. GFA (2019, p. 9) explains that brands are now "demand[ing] more clarity on what circularity means and entails, specifically for design". In addition, although there are many tools available, designers working in industry are not always aware that these exist (Karell & Niinimäki, 2020).

Since, the 2020 commitment, many of the bigger fashion/textile brands have developed their own guidelines specifically for the designers and product developers such as, Nike (2021); H&M (2021); ASOS together with Centre for Sustainble Fashion (2021) and Bestseller (2022a & 2023). While research in academia has predominantly explored how to educate the designers of future, for example, (Hasling & Ræbild, 2018), less time has been spent on exploring how the designers situated within the industry, who did not receive training in sustainable or circular design practice at university, can be educated to push change from within the industry itself. As, Karell and Niinimäki (2019, p. 5) summarise, "a knowledge gap is obvious and even if designers are motivated to include sustainability into their design practices, they need more applied knowledge to implement it".

The previous literature exploring how industry is engaging with sustainability (Palomo-Lovinski and Hahn, 2014; Lawless and Medvedev, 2016; Karell and Niinimäki, 2019 and Karell and Niinimäki, 2020) has mainly focused on smaller fashion brands as well as gaining the perspectives of designers actively pursuing sustainable practices. Therefore, how designers situated in larger fashion brands, not traditionally associated with sustainable and circular practices, has been lesser explored. The challenge this presents is acknowledged by Karell and Niinimäki (2020) who explain that the size of a company plays a role in how easy/hard it is for the designer to suggest and implement change. This is, they explain, due to larger companies having corporate social responsibility teams with a different focus, often broader sustainability, rather than the circularity of the design of garments.

Here Geissdoerfer et al. (2017) help to establish the difference between these two areas (sustainability and circularity). They explain that sustainability goals are more open-ended and benefit the environment, economy and society at large, whereas the circular economy has a narrower focus of eliminating resource inputs and waste from the system. The focus of the latter is the economic actors with primary gains for the environment and only implied gains for society. For designers (those not in leading positions), Karell & Niinimäki (2020) explain their sphere of influence is more limited and would not include social impacts, such as production location and working conditions. Therefore, the focus on the research in this paper is framed within boundaries of circularity.

In addition, this research also considers the circularity education of the designer and/or those involved with product development in context of larger companies. This attention beyond those with ‘designer’ in their job titles is important, as (Palomo-Lovinski & Hahn, 2014) point out “within the present corporate fashion design industry structure, there are several tiers of designers with varying amounts of influence”. Therefore, expanding the boundaries of this research to incorporate everyone in the company who has influence over the design decisions was vital. Going forward the term ‘designer’ will be used to describe this wider group of people involved in product development.

Specifically, this paper examines the research project, ReSuit (Recycling Technologies and Sustainable Textile Product Design) and the work of design researchers at Design School Kolding with industry partner Bestseller. It explores how these industry situated designers can be educated in circular design through their use of Bestseller’s Circular Design Guidelines (Bestseller, 2022a) and investigating the gaps in knowledge that are highlighted.

## ReSuit Case Study

This research is based on the ‘Circular Design Challenge’ hosted by Bestseller as a primary deliverable of the ReSuit project from January to August 2022. This began with the development and publication of their ‘Circular Design Guidelines’ (CDG) version 1 (Bestseller, 2022a). This was specifically aimed at communicating circular design strategies to their own designers.

First, CDG were disseminated internally through a webinar in January 2022. The challenge itself was launched during a workshop, in which brands could explore the circular design strategies in the guide and start developing concepts for circular designs. The final circular garments were presented at an event and exhibition (Figure 1) during Copenhagen Fashion Week in August 2022. A selection of the brands’ designs and how they embody the circular design strategies can be found in the second version of the CDG (Bestseller, 2023, pp. 49-64). This second iteration of the guidelines has been developed by Bestseller together with the Authors based on the feedback, interviews and presentations the brands made and that this paper is exploring.

**Figure 1. Circular Design Challenge Exhibition. © Bestseller.**

## Methods

Eight different Bestseller brands participated in the Circular Design Challenge across markets, including men, women, plus size and children. Interview data was supported by the presentations (Bestseller, 2022b) and published case studies (Bestseller, 2023, pp. 49-64) which have been used to establish insights and draw conclusions. Interviews were semi-structured (Flick, 2009) and conducted online (recorded and transcribed) with a diverse range of designers from each brand that actively participated in the challenge (see Table 1). The interview questions centred around the main areas of investigation, namely, previous experience with circular design, opportunities and challenges from the process and engagement with CDG. Both interview data and the case studies were analysed using thematic analysis (Flick, 2009) to draw out connections and relationships.

| Brand | Job Title |
|---|---|
| 1 | Designer |
| | CSR and Sustainability Responsible |
| 2 | Sustainability Responsible |
| 3 | Designer |
| 4 | Supply Chain Management and Quality Responsible |
| | Design Manager |
| | 3D Developer |
| 5 | Sustainability Manager |
| 6 | Designer |
| 7 & 8 | Creative Buyer |
| | Team Leader |
| | Sustainability Responsible |

**Table 1. Summary of the interviewed designers/product developers within the brands.**

## Findings

Based on the interviews and case studies, the findings will be discussed across three areas of insight:

1. Prior Education
2. Opportunities and challenges
3. Engagement with CDG

### *Prior Education*

While design education in circularity has increasingly become the norm in academic design institutions, (such as the 'Design for Planet' Master's programme at Design School Kolding, MA Regenerative Design at Central Saint Martins and New Landscapes for Change, Fashion/Textile Course at Royal Danish Academy), it is apparent that for the most part the designers working in industry have had almost no prior education within this area.

> *"No, absolutely not. It wasn't a thing at that time."*

This is supported by Karell and Niinimäki's (2020) research in which they explain that *"even though academic research on this area has expanded and tools to support sustainable design have been developed, to a large extent, this knowledge has not been included in design and industry practices"* (Karell and Niinimäki, 2020, p. 20).
Acknowledging the wealth of information available, the designers explained that their education in this area had been obtained informally, outside of working hours and was driven by personal interest.

> *"At that time there was nothing about sustainability at all, so absolutely no education there. My education is kind of self-made – meaning trying to read everything you can. Trying to follow everything."*

Even those that had engaged with the topic as part of a formal education (only 3 of the 12 interviewees) generally expressed the fleeting nature of the content and the emphasis on the student to apply it in practice rather than as a requirement.

> *"We had a little bit when I was in my education, but it was more like a short project where we had a lot of people coming in and talking….we had many people telling us…how we should keep that in mind when we are on our work journey, but not specifically where we have been working directly into garments and products and how we make that more sustainable and circular."*

However, as most of the interviewees were first educated prior to 2015, it was acknowledged that this situation was changing.

> *"I think actually they have applied more hands-on experience now in the in educations than we had."*

### *Opportunities & Challenges*

The research demonstrates that all brands who participated in the Circular Design Challenge found space and time to engage with the design strategies in CDG. While for most this became a project within their working week, one interviewee explained that much of the thinking was done outside of work hours because they were passionate about it:

> *"We didn't have the time to you know, sit down with a whiteboard and start from scratch and it was really a project of interest to do that in the evening or in the weekend."*

For the rest, even amongst busy schedules, they found the additional time required to invest in exploring circular design, dive deeper and learn new things.

> *"Compared to a normal design process for one or two styles…we used I don't know how many hours on this project…. but that was also because everything was new, and you know we just needed to take one thing at a time and then research"*

Challenges were most prominent when the designers had to move beyond activities at their desks and engage with their supply chains to source material, minimise waste in lay patterns and find recovery routes. The challenge pushed them to ask questions they wouldn't normally ask and spend more time creating a dialogue to create change.

> *"I think maybe the dialogues with the suppliers regarding this; how they could reuse the cut offs and how we could optimise on the patterns for the styles for our brand…you need to sit down, take the time with the suppliers and try to get some knowledge from them and also explain to them to understand because we also had to explain to them about this whole concept"*

### *Engagement with the Circular Design Guidelines*

While each brand in the circular design challenge engaged with all areas of CDG, the research found that the design teams' entry point to the design strategies was either at the raw material or the use stage. The former describes how designers engaged with sourcing of raw materials and components especially for a mono-material strategy (linking to the recovery stage).

> *"The raw material was the easiest…that was where we started…Which kind of product and which quality? and then we could work from there."*

> *"Mono composition, I think that's actually quite easy to do. That's just a choice I would say, but that we can do."*

This is supported by Karell & Niinimäki (2020) in which they found that material choice centred the conversation around sustainability. It is therefore unsurprising that this becomes the entry point for designers, as the quote above indicates, because it is an activity they already do, and it comes down to a choice over which materials are available and which they decide to use.

More surprisingly was the engagement related to longevity. Here the designers demonstrated how they implemented classic colours, patterns, shapes as well as designing gender neutral styles (Bestseller, 2023).

> *"It was very easy attacking the concepts, like we can go for non-gender. We can go for untreated; we can go for timeless, durability, longevity."*

This type of designing was based solely at the desk, and therefore was within the designers' control which one interviewee explained didn't challenge them too much. The bigger issue for them was technical durability relevant after the product was purchased by the end user.

> *"It was more the technical part. What if we can't make sure that our end consumer treat the garments as we want them to?"*

However, unlike how the designers engaged with suppliers, asking questions and pushing for change, this starkly contrasted with the engagement with their users. This is common theme for industry designers, as Karell and Niinimäki (2020, p. 14) evidence, "even though product longevity was clearly present in the designers' work in one way or another, the following question arose: How can we ensure product longevity?". One brand acknowledged this short coming:

> *"The end consumer is a huge important thing that we have for many, many years totally overseen because we have just really been focused on, the raw fibre where we have direct impact. So, we really wanted to work with this in consumer phase and by working with longevity."*

Another brand, however, had already started to implement a new testing system for durability of their garments.

> *"So, we of course started with this project testing everything and looking at what is the durability of the fabric, how long can it last... the hardest part was to get the wearable test done…it was people around the office. We told them, you have to wear it for all the days. And you have to write down your feedback on what's happening and then when you wash it, what's happening and all of that."*

While this will certainly provide insights for the longevity of the clothing, it does not address the challenge of increased use. For this, input from the users themselves is required. Only one brand expressed a desire to incorporate this into their process.

> *"It could have been nice to have a focus group…so we can get feedback on what they want, what they're missing out there. So, it would have been nice to have time to actually have that conversation directly with them."*

## Next steps

This area, engaging with the user, has been highlighted as a gap in knowledge and know-how of the industry designer. The CDG would be categorised by Kozlowski, Bardecki and Searcy (2019) as a 'Universal Tool' providing inspirational design strategies that can be freely integrated as required, but are limited with no instruction for use. To overcome this, they suggest these are best combined with and direct 'Participatory Tools' that provide approaches and methods, often through co-design, where designers engage with consumers in the design process. Therefore, this paper proposes that updating CDG with information relating to user engagement and developing a new tool that provides methods for designers to actively engage with their user would help brands to better understand garment lifetime and usage that could be applied to create circular designs.

## Conclusions

The paper explores the issue of educating designers situated in larger fashion brands in circular design. Working with Bestseller in the ReSuit project, CDG were developed and tested during their Circular Design Challenge across 2022. The research explored designers' prior education, opportunities and challenges in circular design and how they engaged with the strategies found in CDG.

The research found that although academic institutions are already integrating circular design into their curricula, the transference of this knowledge into the industry has still not occurred. While there was a clear enthusiasm for learning about circular design, this mainly occurs through individual designers' own interest and motivation.

The creation, dissemination, and application of circular design strategies in CDG were met by the brands whole heartedly. They demonstrated a willingness to spend extra time investigating and learning how design could be done differently and overcame challenges by questioning and pushing their supply chains to change.

While the designers engaged with all aspects of CDG, the researched showed, in the first instance, that the designer explored raw material options and how they could creatively apply design for longevity strategies from their desks. It was highlighted that the teams actively questioned and explored options together with suppliers for production, but lacked the same first-hand knowledge from their users to understand how often and for how long their designs would be used.

The paper concludes that industry designers would benefit from additional knowledge and tools to help them understand how to engage with their users and apply this knowledge towards increased use and garment longevity in their transition towards circular design.

## Acknowledgments

This paper and the research behind it would not have been possible without the support of the sustainability team at Bestseller including Emma Bach Nørbæk and Malene Schalck Rasmussen. We would like to thank all the Brands that were involved in the Circular Design Challenge who gave up their time to be interviewed. Finally, we would like to acknowledge the Innovation Fund Denmark for funding this work as part of ReSuit project.

# Recycled Colour: an exploration of colour sorting strategies for the imperfect design of waste textiles

**Cathryn Anneka Hall(a), Astrid Tolnov Larsen(b)**
a) Design School Kolding, Kolding, Denmark
b) Royal Danish Acadamy, Copenhagen, Denmark

**Keywords**: Textile recycling; Sorting; Designing with waste; Non-woven; Recycled colour.

**Abstract**: This paper explores both colour sorting strategies and design approaches for the mechanical recycling of complex coloured textile wastes intended for non-woven (air-laid-thermal bonded) commercially design products. The demand for scaling and investment in textile collection, sorting, and recycling is rising. However, while contemporary textile production demands perfection and flawlessness, when complex recycled textiles are used as input inevitably, they fall short of these demands. The research explores the issue of colour imperfection in collaboration with Danish textile company 'Kvadrat' and the recycling company 'Kvadrat Really'. It explores how Kvadrat's mixed-colour discontinued textile waste (that is ever-changing and makes uniform repeatability almost impossible) can be sorted and designed for commercial and visible applications for interior purposes. To investigate this, the research draws on visual thinking methods and colour theory, which are tested through material tinkering and hands-on experimentation. A simple colour sorting strategy was developed through the research that could be undertaken by non-designers, resulting in the purest colours possible. However, this strategy alone is not enough to provide a full solution for the use of recycled colour within products. Therefore, various design approaches were investigated, exploring the amount of recycled coloured fibres and the size and amount of recycled coloured flakes that could be used in a textile material. This paper proposes that imperfect materials, such as those that are recycled, can become a key part of the design process rather than an insurmountable obstacle and concludes that exploring the imperfect nature of our materials should be encouraged if we want to extend the lifetime of our resources.

## Introduction

The pressure placed on finite resources by the fashion and textile industry is only increasing (GFA, 2017). The calls to scale and invest in collection, sorting and recycling of textiles are only getting stronger (McKinsey, 2022). Supported by the EU Commission's (2022:2) Strategy for Sustainable and Circular Textiles which aims that by 2030, the textile products placed on the EU market will be “long-lived and recyclable, [and] to a great extent made of recycled fibres”. One of the biggest barriers, as Karell & Niinimäki (2019:10) explain is that “if textile waste material cannot be reliably identified in the sorting phase, it is not possible to direct the material to appropriate recycling processes” and with the wide range of complex textiles the challenge for sorters is to find methods of organising these complex materials for different markets.

During manufacture, the requirements we place on products makes the use of recycled content more difficult. Since the transition from historic craft making to mass production, the irregularities produced by human interaction has almost been eliminated. There is a prevalent trend in Western culture for perfection, homogeneity, and flawlessness in material aesthetics (Rognoli and Karana 2014). For textile recycling, especially mechanical, this is a challenge, particularly as textile waste can be complex comprising mixed fibre and multi colours (Hall et al., 2022). When these complex textiles form the input material for recycling systems, inevitably the result is output materials that fall short of our expectations.

### *Sorting Textile by Colour*

While sorting by fibre type is one method, the complex colour that we design into our textiles is another barrier in order to valorise our waste textiles (Hall et al., 2022). With inefficient sorting colour contamination occurs, resulting in sludgy colours (Hall, 2018). In the wool recycling industry, colour sorting is a vital practice. Norris (2012) explains that textiles are first separated into family colours followed by shades and sub-shades. This can be further qualified as bright, light and dark, referring to depth of colour, shininess and purity. Solid colours can be sold for the highest price whereas 'fancy' mixed colour patterned textiles are sold for the lowest. However, to ensure maximum value, sorters can make several categories of 'fancy', such as red fancy, blue fancy or '10 fancy' (fancy with ten colours in it).

Sorting by colour is not only limited to the mechanical recycling industry, this approach has also been put forward by Niinimäki et al. (2016) as a method to reduce impacts in chemical recycling by carrying forward the colour from textile-to-textile. However, sorting of any form (fibre type, colour or other) the number of categories that are formed are directly relational to the value that can be obtained from the waste. Sorting is a labour intensive activity (Duijn, et al., 2022) and therefore the simplest solutions are sort, thus, a balance between sorting for every colour possible and the appropriate number of categories required for the design needs to be struck. This paper explores these issues, namely, sorting for colour and how it can be designed into new non-woven textiles.

## Kvadrat Really Case Study

This paper investigates research conducted in collaboration with Danish Textile company 'Kvadrat' who produces a wide range of contemporary textiles and 'Kvadrat Really' (shortened to Really) who recycles textile waste into non-woven engineered materials (air-laid and thermal bonded) suitable for interior and industrial-scale projects, such as tabletops, acoustic textiles etc… Specifically, Really products are designed for display and therefore the aesthetics play a vital role, unlike many other non-woven recycled products, such as, insulation and mattress pads that are hidden (Hawley, 2006).

The research centred around Kvadrat's own waste stream, generated when a fabric line is discontinued, and the fabric samples used in their showrooms needed to be discarded. This provides a continuous flow of small squares of textiles, comprised of many fibre types and even more colours and patterns. The research sort to develop a colour sorting strategy and design approach to be applied by Really to their visible commercial applications.

## Methods

The research was split into three sections. First, the colour strategy Really previously established was tested. Second, based on the findings, a new sorting strategy was developed and tested. Thirdly, the new sorting strategy was investigated from a design perspective, focusing on how imperfect colour can be utilised to create new colour aesthetics. To achieve this, visual thinking methods (Arnheim, 1969) and colour theory (Hayter, 1826) where drawn on to explore sorting strategies for complex colour. To test the colour sorting strategies a material tinkering approach (Parisi et al., 2017) was employed to conduct hands-on experimentation (described as lab trials) towards a product application. Both reflection-in-action (Schön, 1991) and an after action review method (Morrison & Meliza, 1999) was used to draw together the findings presented in this paper.

### *Lab Trials*

Lab trials were conducted using Really's production/lab test procedure. This involved cutting the discontinued samples into strips and mock-recycling them using a coffee grinder or cutting them into flakes mimicking the industrial recycling processes (Figure 1). Each lab trial was made up of 70% recycled textiles (either solely recycled from the discontinued samples or in combination with white recycled fibres Really already uses, produced from commercial laundry waste). The final 30% was binder fibres (bicomponent fibre) that enables the thermal bonding, under heat and pressure, of the non-woven material. Each lab trial weighed 4g and was heated using a simple heat-press mimicking the industrial production.

**Figure 1. Discontinued Samples cut into strips and recycled into fibre.**

## Colour Sorting Strategy One

Prior to this research, a sorting strategy had been developed by Maria Viftrup to try and make sense of the continuous shifting nature of mixed colour/patterned fabrics from this waste source. While Really's product is higher value than many hidden non-woven applications, the colour sorting, as with most sorting in the industry, would be conducted by hand. It was, therefore, imperative that the strategy was simple and easy to implement.

Maria divided the colours into four categories: LIGHT, DARK, WARM and COLD (Figure, 2). Using discontinued samples provided by Kvadrat, this strategy was actively employed by the authors (Figure, 3).

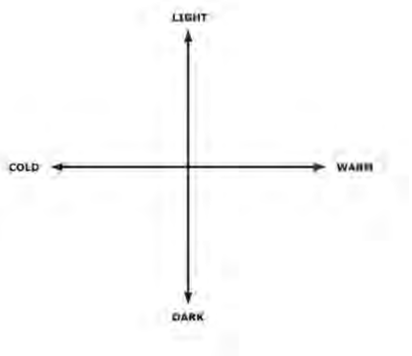

**Figure 2. Colour Sorting Strategy One © Maria Viftrup.**

The physical sorting raised many questions about the location of certain colours and colours that could be placed into multiple categories. One particular fabric appeared lighter when placed next to a darker colour and the opposite when located next to a lighter sample. Small amounts of each discontinued sample from each category were used to create the lab trials and no additional textiles where added, so the true colour could be assessed (see Figure 5 overleaf).

**Figure 3. Sorting Strategy One.**

### *Colour Theory*

In colour theory (Hayter, 1826), a hue is a pure colour. A tint is a colour combined with white increasing lightness, while a tone is a mixture with black increasing darkness. Whereas a shade is produced either by mixing a colour with grey, or by both tinting and toning (Figure, 4).

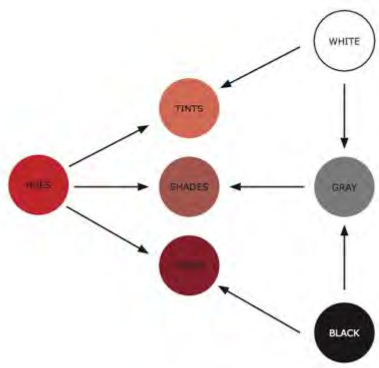

**Figure 4. Colour theory of tints, tones shades and hues.**

The main challenge was that the discontinued samples were a mixture of colours and patterns, that individually encourage tinting, toning as well as creating various shades. However, above and beyond this, all categories, except from LIGHT, combined both light and dark samples which encouraged further tint and tone resulting in a 'dirty' or 'muddy' shade. This included the DARK category which included 'lighter-dark' colours unsuitable for the LIGHT category. LIGHT also faced issues because both blue and yellow samples were combined. This created neither light blue nor light yellow, rather a dirty green, muddied by the grey samples also present. The result was a range of four 'muddy' colours commonly associated with low value recycled materials (Figure 5).

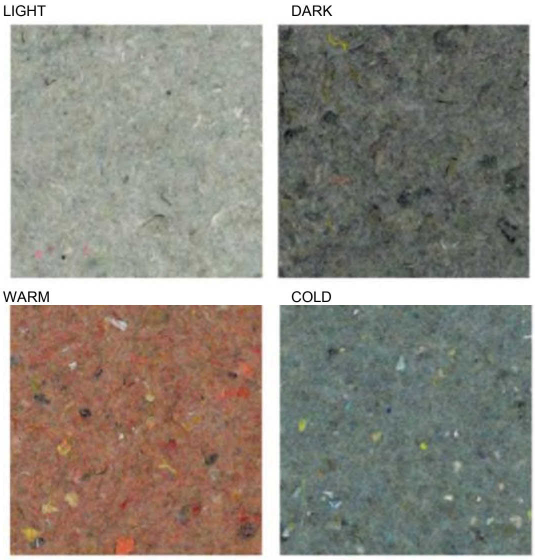

**Figure 5. Lab Trials of Sorting Strategy One.**

## Colour Sorting Strategy Two

Based on the results of strategy one, a new strategy was developed. First, small squares of each discontinued sample was taken and visually organised into a colour wheel (Figure 6). This way of displaying the samples allowed the researchers to discuss the location of specific colours, highlight samples that were problematic and adapt the wheel until solutions where reached. The wheel also indicated the quantities of each colour category that might be expected. For example, there was significantly fewer green fabrics, and therefore in production this would provide a small batch of fibres for use in Really's applications.

**Figure 6. Colour Wheel used to develop Colour Sorting Strategy Two.**

One of the challenges was establishing the location of the fabrics that could fit into multiple categories. As design researchers, the authors were conscious that their decision making was influenced by tacit knowledge regarding colour and design. In reality, this sorting task would be undertaken by non-designers. Therefore, it was vital that the categories and any rules should be easy to follow. An inner circle of problematic colours was created with string linking the colours across categories. For example, there were many fabrics that were between the fresher blue fabrics (left) and warmer cream fabrics (right).

### *From Four to Six Categories*

After analysing the colour wheel, six new categories emerged. LIGHT was divided into FRESH and SOFT to avoid combining colder light green/blue/greys with the warmer pink/orange/yellow/creams. COLD was divided into FERN (green colours) and OCEAN (blue colours). Therefore, as the lighter warm colours have now been redirected to SOFT, this resulted in a purer set of red and orange fabrics named LAVA. Finally, due to all the changes, DARK was now streamlined including only very dark fabrics, avoiding muddy shades, and was renamed NIGHT (Figure 7 overleaf). Lab trials were conducted to test this strategy and resulted in six core colours that were purer and brighter (Figure 8 overleaf).

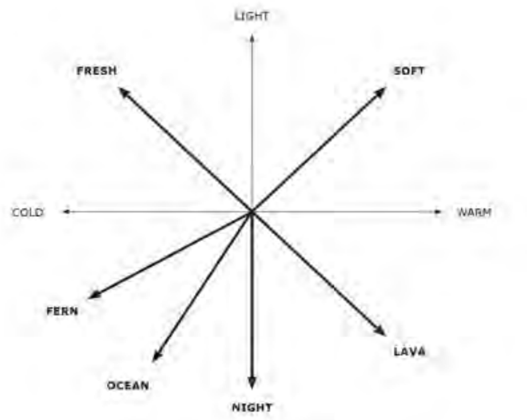

**Figure 7. Colour Sorting Strategy Two.**

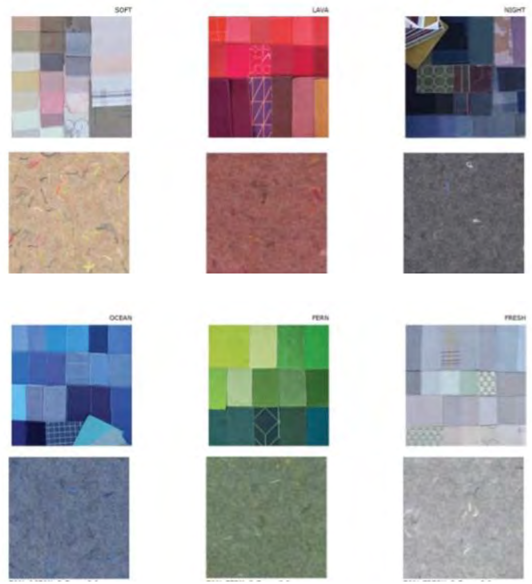

**Figure 8. Colour Sorting Strategy Two fabric and lab trials.**

### *Challenge of Yellow*
One issue specific issue was yellow, as this only formed a small proportion of the overall colours. Therefore, deciding the location was discussed at length. If placed in LAVA, the result would be an more orange/red. There was also an option to combine it with FERN or SOFT. After a series of lab trials (Figure 9), the authors concluded that yellow was most effective at brightening up SOFT. This decision also considered that the discontinued samples used in this experiment might not be representative of those discontinued next month/year – what if there was a trend for yellow fabrics in the future? Where would this larger volume of yellow fit best?

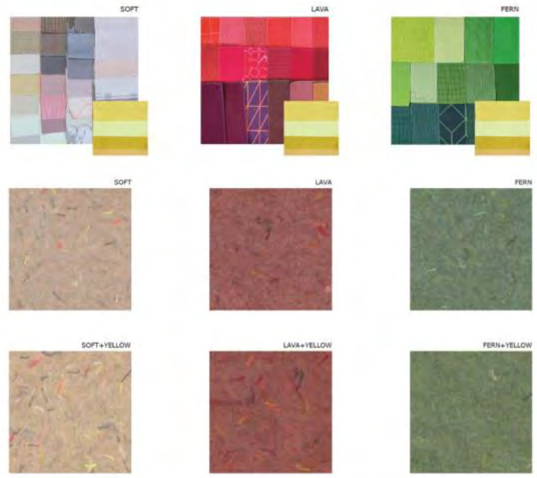

**Figure 9. Sorting for Yellow Lab trials.**

## Imperfect Colour in Design
Although the sorting strategy had played a vital role in creating purer colours, these alone wouldn't be suitable for commercial applications in the Really brand, as they were too bold for their applications. In addition, the lab trials only provided an indication of the colour that could be achieved. In reality the discontinued samples would be ever-changing with the new production of Kvadrat textiles. Therefore, the question for the researchers was how designers can work with changeable imperfect colour?

Imperfect is not a new concept in design, zen aesthetics, known as Wabi-Sabi, use imperfection, asymmetry, and asperity to achieve aesthetic pleasure (Hvass, 1999; Juniper, 2003; Koren, 1994). Imperfection, can also make users' experiences richer and more enduring (Rognoli & Karana, 2014). Therefore, what is seen by modern manufactures as flaws, can not only be used to address complicated textile waste but also contribute to further extension of the product lifespan.

### Three Colour Experiments
To use the recycled colour the authors used a material tinkering approach to explore how it might be combined with recycled fibre Really already uses in production. This is pure white and is sourced from worn out white linen table clothes and bedsheets from industrial laundries. This enabled design exploration of recycled colour tinted with white. This led to two

investigations, recycled colour as fibres and recycled colour as flakes.

### *Recycled Colour – Fibres*

In this set of lab trials, each sorted colour category was recycled back to fibre. As with all lab trials the binder remained at 30%, leaving the remaining 70% textiles to be the changing factor. Four lab trials were conducted for each colour category: 55%, 35%, 15%, and 5% recycled colour (Figure 10).

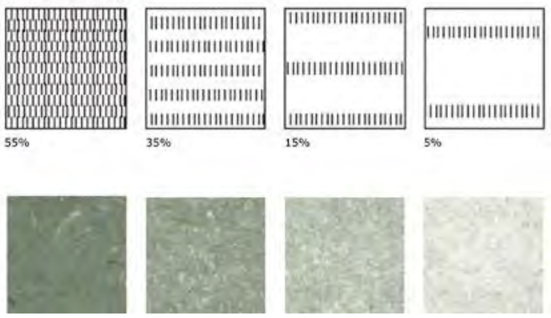

**Figure 10. Recycled Colour – Fibre Lab Trials**

### *Recycled Clour - Flakes*

Additionally, rather than take the textile all the way back to fibre, Really highlighted that they were able to recycle the textiles into flakes. Therefore, this led to two set of lab trials. The first was to explore the size of flakes, and the second, based on the results of the size, the quantity of flakes within a sample.

For the first lab trials, the composition was 55% white recycled textile, 30% binder and 15% flakes of recycled colour. Three sizes of flakes were tested: 12mm, 6mm and 3mm (Figure 11).

Reflecting on Really's applications, the authors assessed that the 12mm flakes were too big, as you could clearly see some of the patterns from the textiles on the flakes. Not all patterns would be desirable, and as discontinued fabrics the assumption was that the aesthetics would have fallen out of favour. Conversely, 3mm flakes were too small, as the recycling process transformed some of the flakes into fibres which coloured the background and looked too similar to the trials with fibres.

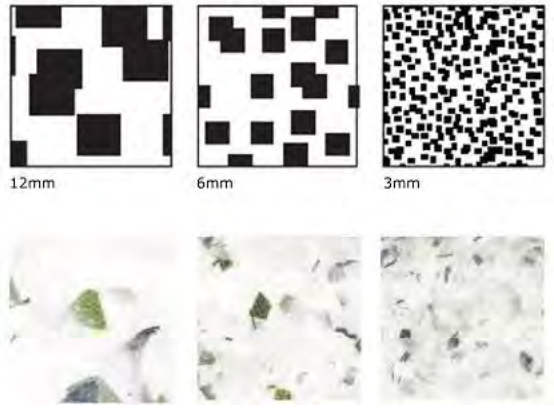

**Figure 11. Recycled Colour – Flake Size Lab Trials**

Therefore, the second lab trials used 6mm flakes and explored the percentage of flakes., Four lab trials were created for each colour category: 55%, 35%, 15%, and 5% recycled colour flakes (Figure 12).

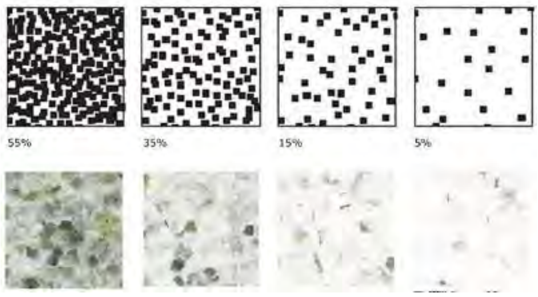

**Figure 12. Recycled Colour – Flake Quantity Lab Trials**

### *Findings and Next Steps*

Through this research creative design was applied to both colour sorting and material development, both of which had to overcome imperfect colour. Imperfection was a dominating focus of the brief and therefore, we argue that this can become a key part of the design process rather than an insurmountable obstacle. Combined, the sorting strategy and design experimentation enabled a range of approaches to be found. First the sorting strategy, aided development of purer recycled colour and helped to control colour contamination in the final material such as what colour imperfect flecks in the fibres would be. The design exploration also helped control how much pattern could be seen in the flakes (Figure 13 overleaf).

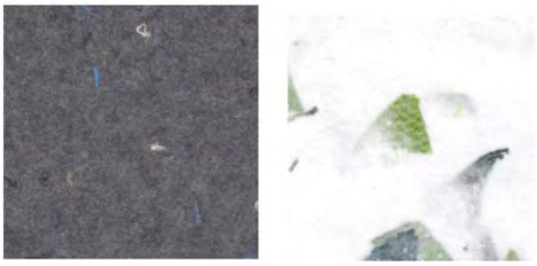

**Figure 13. Coloured fibre flecks present in the lab trail (left) and patterned colour present in lab trial (right)**

We also argue that designing with imperfection does not need to be limited to small scale craft practice, but can be integrated into the design of commercial industrial textile materials. While the outcomes were never tested at scale nor explored within a product application, the exploration was develop within the constraints of industry (both process and product). This meant that strategies produced could be implemented by non-designers and the material aesthetics were designed to be produced by current manufacturing processes.

We reason that it is through tinkering within these industrial boundaries that makes this design approach possible. However, this is not a method of selectivity, which Sherbourne (2009) explains is where the designer creates value by being selective of the materials they work with. Across each step, the authors accounted for all the discontinued sample waste, in all its complexity (patterns and colours), avoiding the unselected materials going to waste. This does not mean, however, that all colour categories must be treated the same, some could be utilised as fibres others as flakes. Those categories that consist of great quantities of textiles could be utilised for both. These are all avenues highlighted for further enquiry. Ultimately, the research proposes, that experimenting and exploring the imperfect nature of our materials should be encouraged if we want to extend the lifetime of our resources.

## Conclusions

This paper explores how Kvadrat's complex mixed-colour discontinued sample waste can be sorted, recycled, and designed towards new products that would be created using Really's manufacturing processes. To achieve this, the research investigates strategies for colour sorting so that the resulting recycled fibres can be designed into non-woven textiles for a visible commercial application. This is particularly challenging when the waste stream is ever changing in pattern and colour making repeatable and uniform output impossible.

Six colour categories were developed that could be sorted for by non-designers, resulting in the purest colour possible. These colour sorting categories alone do not provide a full solution for their application into a product; thus, various design approaches were explored, from the amount of recycled coloured fibres to the size and amount of recycled coloured flakes used in a material. This paper proposes that imperfection in materials, such as those that are recycled, can become a key part of the design process rather than an insurmountable obstacle and concludes that exploring the imperfect nature of our materials should be encouraged if we want to extend lifetime of our resources.

## Acknowledgments

This paper and the research behind it would not have been possible without the support of Kvadrat Really including Wickie Meier Engström and Troels Theilby. This research also forms part of Author, Astrid Tolnov Larsen's doctural research which is funded by the Royal Danish Academy.

# Authentic Pre-loved luxury – sustainability concern?

**Henninger, C.E.[a], Amasawa, E.[b], Brydges, T.[c], Hanlon, M.[d], Yan, S.[a]**

**Keywords**: Luxury; Fashion, Pre-loved; Sustainability.

**Abstract**: This exploratory study focuses on the second-hand or pre-loved luxury fashion market. More specifically it explores different types of resale models that have gained increased popularity and are often classified within the circular economy remit, as they are seen to make use of already existing resources – here pre-loved luxury items – by re-looping them into the consumption process. Yet, a question that emerges and is explored is in how far these business models are actually sustainable, seeing as pre-loved luxury goods often are exported and imported multiple times, in order to satisfy consumers needs to have authentic goods. There is a thriving luxury resale market, where pre-owned luxury fashion goods are sold to consumers worldwide. To ensure the authenticity of these items, luxury authentication companies are often utilized. These companies are frequently located in overseas countries, outside of Europe, the UK, and the US. Luxury items are sent to these companies for authentication before the resale process is completed, adding to the environmental footprint of these items. By following different business models and their supply chains, this research seeks to shed light on environmental sustainability aspects of these 'circular approaches' to reselling pre-loved luxury fashion items.

## Problem setting

This research focuses on the luxury pre-loved resale market, which has seen a rapid increase especially since the pandemic. This can perhaps be explained, seeing as the cost-of-living crisis has implied a reduction in disposable income, yet people may still want to enjoy luxury items, just not at full price (e.g., Berg et al., 2021; FT, 2023). A further explanation can be an increase in environmental consciousness, with pre-loved items being seen to be more sustainable (e.g., Pocinkova et al., 2023). Sustainability here encompasses all three elements of social, environmental, and economic aspects, whereby sustainability is 'achieved' at the intersection of all three (e.g., Henninger et al., 2017a; Fletcher and Tham, 2019).

Even though the luxury resale market has gained attention and is increasingly attractive, Lazazzera (2023) highlights "authentication costs are onerous, and opinion is divided over which business model will be the key to long-term success". To explain this further, wearing a luxury item is a conscious decision and linked to an individual's identity, in that they bought into a brand and thus, a luxury lifestyle, with which they want to be identified (Henninger and Athwal, 2022). Wearing an authentic piece, meaning one that has been produced by one of the luxury brands, is vital here. Within the luxury industry 'fakes' have increasingly penetrated the market, which has become an issue not only for luxury brands, but also for consumers. Within cultures, such as China, being spotted with a 'fake' luxury item can imply losing face and is thus seen as highly undesirable (Henninger et al., 2017b). Thus, it may not be surprising that new business models have emerged that specialize in authentication of luxury products, which are now often used by different resale platforms in order to satisfy customer needs to gaining access to 'true' or 'authentic' pieces of luxury fashion.

Prior to discussing the implications of having authentication services, which is further explored later on, it is vital to explain the concept of circularity, as resale models have been associated with this concept. The circular economy has become a buzzword in the fashion industry, heralded as a potential solution to the fashion industry's waste problem

(Amasawa et al., 2022). The circular economy concept can be seen to be borne out of the fast fashion make-use-dispose production method that has come to dominate much of the industry and is seen to be unsustainable and in urgent need to be changed (Henninger et al., 2021; Brydges et al., 2022). According to the Ellen MacArthur Foundation (EMF, n.d.) within a circular economy "we can eliminate waste and pollution, circulate products and materials, and regenerate nature, (by) creating an economy that benefits people, business and the natural world". Thus, it can be said that approaches falling within the circular economy approach follow a reduce-reuse-recycle framework, which can describe both closed and open-loop systems that address concerns on the consumption and production side (Blomsma and Brennan, 2017; Dagiliene et al., 2021).

## Resale and the circular economy

Although the circular economy has become a buzzword, as alluded to earlier, within the fashion and textile industry only a limited amount of textiles are actually recycled. Depending on the source that is being consulted, the number varies from 1% to 12% (e.g., Beall, 2020; WRAP, 2020). This has various implications, on the one hand, circular economy strategies can be seen as 'add-ons', that may have been introduced in order to satisfy the sustainability agenda of an organisation, whilst on the other hand, re-looping materials can be challenging, seeing as the quality of raw materials (fast fashion garments) have been described to be of low quality (Brydges et al., 2022). Niinimäki et al. (2020) pointed out that the latter issue has contributed to an increase in post-consumer waste that has now ended up in landfill, as materials are of too low value to be reused.

Addressing challenges in the fashion and textile industry can neither be solved in isolation nor can they be solved by adding on strategies that are claimed to be more sustainable. Rather, making changes to the current system implies an actual system thinking approach (Niinimäki, 2017). This idea also aligns with what Fletcher and Tham (2019) term the Earth Logic, which implies that flora and fauna should be in harmony and reach an equilibrium in which both can co-exists without resource depletion. As such, the circular economy is seen to foster this equilibrium by facilitating new system thinking approaches and changing current practices to meeting current and future needs of generations, by also considering not to negatively impact the social and natural environment. Within the academic literature, environmental and social sustainability challenges caused by the currently dominating make-use-dispose production method are well-established (e.g., Henninger et al., 2016; Bick et al., 2018; Niinimäki et al., 2020), there is a growing body of research investigating the opportunities and barriers in the transition to a more sustainable fashion industry.

As stated at the beginning of this paper, within this research the focus is on the resale model of luxury fashion item, which falls within the frame of the circular economy, as already existing products, here pre-loved luxury fashion items, are kept within the consumption loop for longer, be recirculating items once they have reached the useful life for one owner to than be passed onto the next. Thus, the resale model enhances the useful time of an existing product, by re-circulating it into the consumption process (Henninger et al., 2021; Amasawa et al., 2022). Although extending the useful life of garments and/or accessories can have positive environmental impacts, with the EEA (2019) outlining that using an item for an additional 9 months can reduce carbon emissions and water wastage by up to 20%, the question that remains, whether this is always a sustainable option? For example, fashion resale does very little (if anything) to address the significant, and ongoing, environmental and social (such as workers' rights) sustainability impacts embedded within our clothing. Yet, it is seen to be 'more sustainable' as it implies no new products are being produced, but rather already existing ones are recirculated.

## Market Overview

Luxury fashion resale is a growing segment of the second-hand market, McKinsey and Company (2021) estimated that this sector (luxury fashion resale) is worth $25-30 billion in 2020. Yet, less is known about the environmental impacts of this circular business model. Rather, a core area of research has been around the challenges of counterfeit products with consumers highlighting they have been afraid of purchasing second-hand, as being seen to wear a 'fake' is seen as a high social risk. As one response, a number of businesses have honed in on this issue providing authentication services, which implies that consumers, or re-sale platforms alike can send their items to these platforms to gain an authentication certificate for the product (e.g., Entrupy, 2022). These certificates are often included with the sale of a luxury product as a way to enable subsequent sales of a luxury product on the second-hand market. However, sending products to an authentication service implies packaging and shipping items from one place to another, which has environmental costs.

## Research Outline And Conclusion

This research seeks to explore how environmentally sustainable luxury fashion resale business models may be, by not only gaining insights from the industry, but also consumers, within and across various contexts. It also seeks to trace the highly obfuscated, globalized supply chains that luxury products can follow, as a growing number of luxury resale items seem to be imported into contexts such as Australia, North America and Western Europe from countries such as Korea, Japan, China and/or Singapore. With an interdisciplinary, mixed-methods approach, this research capitalises on life cycle thinking to understand the environmental impact that could be associated with luxury resale models. This will allow for an exploration of a number of factors that can shape the environmental impact of a luxury item, such as transportation and packaging.

This research will have significant implications for the luxury fashion industry and sustainability. It explores environmentally sustainable luxury fashion resale business models, aiming to drive change and encourage more sustainable practices. By gaining insights from industry and consumers, the research can identify barriers and develop strategies. The research also traces globalized supply chains, identifying opportunities to reduce environmental impact from transportation and packaging. Using an interdisciplinary, mixed-methods approach and life cycle thinking, this research sheds light on factors that impact luxury items' environmental impact, driving a more sustainable industry and broader sustainability efforts.

# Repurposing and production – So what's the issue? Reflecting on how the production system can be affected by new circular material flows

**Fredrik Henriksson, Marie Jonsson**
Linköping University, Linköping, Sweden

**Keywords**: Repurposing; Production System Development; Flexibility; Case studies; Circularity.

**Abstract**: On the path towards a circular economy, new ways of making and producing must be implemented on an industrial level. While there are methods for remanufacturing, the topic of repurposing on an industrial scale is still not fully explored and systematized. Repurposing, in this paper defined as the process of re-using products or components but with other functions, or modifying products or components for use in other products, will have a distinct effect on the production system and will challenge the current idea of production system development. In this paper, the authors use four different cases (three implemented in industry, one current design project in an academic-industrial partnership) to reflect on how the production system will be affected by certain aspects of repurposing. In total, five topics of production system development (Material classification, Product definition, Logistics & material handling, Manufacturing processes & planning and Processing window) are highlighted in the analysis, and some concluding remarks about flexibility needs and integrated development processes are presented. This paper does not provide clear answers or methods on how to implement repurposing but highlights multiple areas where further research is needed in order to make repurposing easily accessible and possible to implement for small and medium-sized manufacturers in their regular, daily work.

## Introduction

With increased focus on sustainability, the efforts to minimize the amount of material going to material recycling might require another level in the waste hierarchy: repurposing. While some very successful repurposing projects have been finalized both in academia and industry, a significant upscaling in production volumes (going into the four to five-digit production numbers annually) will create the need for a more rational and streamlined production system. What happens when this is done?

In this paper, the authors reflect on how the production system can be affected by implementation of repurposing in mass production. Using some existing cases as a background, the authors expand and extrapolate to find connections in existing production system literature or theoretical "black holes"; areas where the authors can identify a knowledge gap.

## Repurposing

On the path towards a circular economy, there is a collective effort to reduce the amount of virgin material being but into products that are later put into landfills or only used for energy recovery. One way of explaining this is via the waste hierarchy, as defined by the European Commission in their Waste Framework Directive (European Comission, u.d.); as little as possible of the material used should be going for disposal, and as much as possible should be done to prevent waste before it happens. Within this hierarchy, between "recycling" and "preparing for re-use", we place repurposing. Cramer (2017) defines repurposing as "re-use product but with other function", but we want to add "use product as a basis for other products" as an alternative. Repurposing is hereby defined in the article as: a design and process that takes products that are worn out beyond being repairable, or products that are not wanted by the market, and transform them or as much as possible of them into other products as efficiently as possible. This process differs from remanufacturing in such that the resulting product is significantly different from the primary product in geometry or functionality.

## The production system

Production is the process (or connected processes) to manufacture material(s) into products. The *production system* is what makes this possible, by organizing the operations, collecting needed resources, and transforming them through a (set) sequence one or more manufacturing processes (Bellgran, 2009). Processes are either carried out by a human or by a machine, which in turn relies on supporting processes like procurement, quality, design, process planning, IT etc. to perform the task. Therefore, the production system consists of several sub-systems, organized towards the goal of the manufacturing company - to produce cost competitive goods at a desired pace and a desired quality. A black box approach, inspired by Groover (2015), is used to describing the production system and presented in Figure 1. For different products and/or companies, the parts of the production system may differ. For this paper, focus will be on some of the main processes and sub-systems – the manufacturing processes, the machines and equipment, procurement, process planning and design.

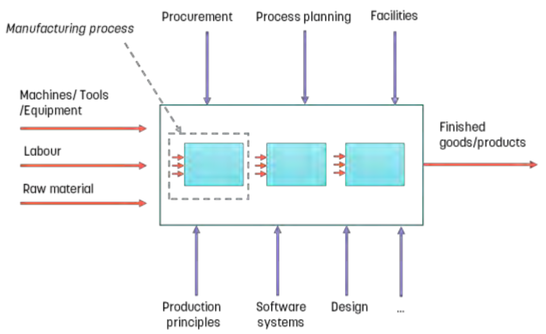

**Figure 1. A schematic representation of the production system.**

Many manufacturing companies, especially high-volume manufacturers, use overarching production principles to guide their production system and how they organize production. Many base their set of principles on Toyota Production System (TPS) and/or Lean Manufacturing. The similarities and differences between these two are often debated, and for the purpose of this paper, they will be grouped together. Both are focused on solving problems and eliminating waste in manufacturing to achieve customer satisfaction and making work easier, less burdensome, and more meaningful for the workers. Lean production literature has highlighted multiple waste aspects (Ohno, 1988).

## Case studies

Here, the authors present 4 cases that will be used to analyze the effects of repurposing on a traditional production system, highlighting different types of repurposing and products.

**Figure 2. Stolab's Lilla Snåland. © Meijers Möbler.**

### *Case 1 – Stolab's Lilla Snåland*

The Swedish furniture company Stolab launched the stool Lilla Snåland in 2017. This stool is designed from internal production waste, with the seat being made from 14 triangular pieces (as can be seen in Figure 2) that are wasted in the production of the company's famous chair Lilla Åland (Stolab, u.d.). The designer, Marie-Louise Hellgren explicitly designed the Lilla Snåland to use these off-cuts, in an effort to increase the company's sustainability profile. In this case, the material used is well-defined and has very small variations and deviations and is well-known in the process.

**Figure 3. Freitag messenger bag F13 Top Cat. © Freitag.**

### *Case 2 – Freitag's tarpaulin backpacks*
The Swiss fashion company Freitag makes their messenger bags out of recycled tarpaulins (seen in Figure 3), sourced from logistics companies when they have been discarded for use on their trucks and trailers (Freitag, u.d.). These tarpaulins are often brightly colored and decorated with company logotypes, which are used as the basis for the graphics on the messenger bags. While the material used is external, the format and dimensions are clearly defined due to their primary use. On the other hand, the graphics and their placement are not known in advance, and there could be wear and tear on the tarpaulin in different areas not known beforehand.

**Figure 4. Andra Formen Hovrätten 02, a desktop lamp made from an e-scooter. © Andra Formen**

### *Case 3 – Andra Formen's E-metabolism project*
Swedish design collective Andra Formen has in their E-metabolism project made furniture and lamps out of e-scooters found in the water in Malmö harbor (Andra Formen, u.d.; Andra Formen, u.d.). While not being in large-scale production yet, the concept behind the project highlights some specific challenges and is therefore included in this case study. In this case, the main product might be well-known on a higher level of abstraction but deviations between different suppliers could exist along large variations in quality due to aspects like time submerged in water and use case before submersion.

### *Case 4 – Building waste furniture*
In an ongoing project in collaboration with Linköping University, a large Swedish contractor and builder is currently investigating how to use waste created on building sites to design and manufacture public furniture to be added to the newly developed sites. The idea is to use commonly wasted materials from the building site, with no easily defined other use (to exclude excess materials, since they could be shipped to another site for use there), to increase their value without wasting the built-in resources of the materials. This will be done by building additional structures that will add value for the users.

## Analysis
Based on the 4 cases the authors have identified 5 affected areas linked to the production system: *Material classification, Product definition, Logistics & material handling, Manufacturing processes & planning* and *Processing window.* These will be further elaborated below and related to the cases, and in some cases further developed for a future state.

### *Material classification*
Manufacturing processes like machining, bending, etc. rely on previous knowledge of the material specification to be carried out successfully and in many cases, manufacturing tools and equipment is adapted to a specific material. Also, the resulting product itself has been specified to achieve certain quality targets

and functions, linked to the material properties. With repurposing, the specification of the

incoming material might vary more extensively than in traditional manufacturing, where material is sourced to tighter specifications. In repurposing, material geometry / dimensions might vary, as well as material properties like ductility, hardness, density as well as aspects like surface roughness or color. This complexity of material information and documentation is further adding to the challenges of managing materials in the product development process (Henriksson, 2021), where challenges regarding production is central topic when trying to for example introduce new materials in products (Henriksson, 2017; Henriksson, Davidsson, & Detterfelt, 2020). With repurposed material, the amount of information the system needs will increase in relation to the differentiating aspects of the incoming material. This will increase engineering time needed for process planning and information creation, or systems support must be developed for on-the-fly / automatic generation of the needed information. The issue is multiplied if the incoming "Material" is more complex, like in case 3, where an existing product is deconstructed and repurposed into a new product. For an automated system to do this, the incoming material must be thoroughly understood and documented, or an extensive information collection must be made and the production system adapted to suit.

### *Product definition*

Linked to material classification is the impact on product definition. Usually, companies define their product in a BOM – Bill of Material structure, which can be described as a hierarchical tree structure of the products parts. Each part in turn, might be further defined with drawings, or other information documentation describing for example surfaces, or standards to which the part/component must adhere to. For manufacturing, the BOM and the part definitions are used to create the Manufacturing Bill of Material (MBOM). This is also often represented as a hierarchical structure but describing the different "states" the parts have as they are produced. For example, a shaft connection is at a certain stage in manufacturing a block of metal in the MBOM, while in the BOM it has the final form. With repurposed material, the BOM and MBOM will have to be more dynamic, adapting to the sources of incoming material. While dynamism of the BOM has been discussed by others (Ginsburg, u.d.), this adds a new level of complexity. Many software systems for product management and definition have the capability to manage different product configurations. Currently, product configuration is design driven and cascaded "top down", but with repurposing product configuration might be the same, but the available material and the corresponding processes needed will differ. It is the author's opinion that repurposing has to be considered early in product definition to be carried out successfully.

An example of this could be seen in case 3, where the detailed knowledge and definition of the incoming material (the e-scooter) could vary; different e-scooter manufacturers might use slightly different materials, and different dimensions to achieve similar product performance. This variation will, in the case of repurposing, flow into the next manufacturing process and affect how the MBOM will be set up (with some variants, there might be a need for additional process steps, for example).

### *Logistics & material handling*

As the product routing might vary, the internal logistics, storing and warehouse operations will be challenged. Many companies working with Lean/TPS production principles favor "Just-In-Time" material delivery and keep stocks low. This means business models must be set up where companies can be sure of a steady material supply, so they do not have to keep safety stock. For other companies, like Andra Formen, the supply might always be difficult to predict, and they must adapt their operations to an uneven material supply. Repurposing, however, may offer companies a path to supply chain resilience, as the pool of available material is increased. Material handling in manufacturing processes, i.e., the handling of material in and out of machine, will be more difficult with the material variations as described in *Material classification.* Handling equipment such as grippers, chucks and fixtures will be affected and companies either must keep multiple variants or make them flexible, modular, or adaptable to handle the incoming material, as has been discussed by Jonsson & Ossbahr (2010). Variants of this can be applied to multiple cases; in Case 3, there is a challenge in managing logistics from different sources to the production site, and with sometimes unclear sourcing pathways, while in Case 4 it could be a case of intraorganizational, intersite logistics if a certain building site lacks a key material while another has this key material in excess. These logistics are not necessarily more complicated than the traditional provider-to-purchaser logistics, but this more complex system can add possible failure and pain points.

### *Manufacturing processes & planning*

As explained earlier, a certain product is produced with a set chain of manufacturing processes (often called a routing). For each of these work instructions have been created to capture and explain how the product is manufactured. They can be in the form of work instructions (for humans), programs (for machines) or drawings. To use repurposed material in the product, means that the routing between products might differ. For the same product, the manufacturing sequence might go from A -> B -> C to A -> B -> D -> C, for example to add a cutting operation for a repurposed, but too long, metallic rod. Depending on the setup, implementation complexity varies. In some cases, the physical layout of the manufacturing may hinder this. Also, the information system setup, product definition and process planning must allow for this flexibility.

One example of this challenge can be seen in Case 2, where the placement of the cuts from the tarpaulin will affect the end quality of the product. Both in terms of product quality (the tarpaulin might be damaged), and in terms of design quality (some parts of the graphics might be more visually appealing to cut out and use for the bag).

Another challenge for production planning could be the interdependence of multiple products in the portfolio. In Case 1, where the product is made from internal waste streams, this creates both an upper limit to the production volumes of one product (since you cannot produce more Lilla Snåland than the waste generation allows for) and another dependency in the planning; to produce the stool, you first need to produce the products that generate the waste. This adds complexity to the production planning, especially if the production system needs low down-time to be economically viable.

### *Processing window*

The processing window, or the maximum deviance allowed for a certain parameter that affects the production system behavior. Traditionally, this has been not exploited fully since quality issues may occur more frequently in the outer regions of the process window, but with repurposing and different material sources, a large process window and full knowledge of the quality variations throughout the production window may become more important for a production planner.

Some of the challenges here can be seen in Case 3 and 4, in different aspects. Looking at Andra Formen's project, they are using post-consumer waste material streams of high value. Since this material is post-consumer, it is less conformed and might vary more in quality than for example internal waste stream. This also affects the processing window since the production process must in some way accommodate these variations without creating subpar products. In Case 4, the building waste furniture, the waste material is more varied and of lower value, meaning that there are challenges in setting up a production system that is able to manage these variations in type while the quality might be more conformed.

## Concluding remarks

The above analysis is not exhaustive but highlights that repurposing in higher volumes will challenge the production system. Although many companies strive for mass-customization, i.e., combining personalized and/or custom-made products with the low unit cost of mass production, it is often a vision, and companies must choose the level of flexibility in their production system to manage it efficiently. Like with mass-customization companies will have to identify at what level they can incorporate Repurposing, and what variation of incoming material they can handle without increasing unit cost to an unacceptable level. Adapting the flexibility definition of ElMaraghy (2006) to repurposing, we define it as the operative ability of a manufacturing system to switch with minimal effort or delay within a pre-defined product family and material pool by re-programming, re-routing or re-scheduling the same system. Based on Sethi and Sethi (1990) who identified 11 categories of flexibility (Machine, Material handling, Operation, Process, Routing, Product, Volume, Expansion, Program, Production and Market) we can see that the one's most relevant to Repurposing are Machine, Material handling, Operation, Process, Routing, and Product. However, it should be noted that much of the classical literature and research on flexibility in production is not done with circularity in mind and some of the categories must be redefined for this new approach.

Also, many companies strive to develop the product and production system concurrently (Andreasen & Hein, 1986; Prasad, 1996). This is challenging also in traditional, linear manufacturing settings. It becomes more challenging if the product definition is flexible to take different material sources into account. Instead, it might be necessary to increase the level of flexibility in the product domain.

We are currently moving into the Industry 4.0 era, where machines, humans and systems are connected, and data is collected and utilized to create value in different ways. This will heavily support Repurposing, as the product and material definitions can be seamlessly transferred between systems and for example, AI or other software automation can be used to adapt programming, drawings, work instructions etc. On the hardware side of operations however, the challenge remains to create mechanical solutions that can be adapted to different material specifications.

## Acknowledgments

The authors would like to thank My Oddsberg Hindersson and Alma Swärdh for their work in projects leading to the making of this article.

# A diary study set-up to identify thresholds for repeated usage of reusable products

**Laure Herweyers [a], Ingrid Moons[a,b], Els Du Bois[a]**
a) University of Antwerp, Faculty of Design Sciences, Department of Product Development, Antwerp, Belgium
b) University of Antwerp, Faculty of Business and Economics, Department of Marketing, Antwerp, Belgium

**Keywords**: Reuse behaviour; Long-term behaviour; Habits; Sustainable design; Diary studies.

**Abstract**: After the European ban on several everyday single-use plastic items, there is a need for sustainable alternatives that can be integrated into people's daily routines. This research focuses on possible thresholds that prevent the repeated usage of reusable alternatives for single-use products. The research questions are: (i) What habits in the daily life of the consumer impede the use of these products? (ii) What are the differences in user thresholds between an 'on-the-go product' and a product that is used at home? (iii) What characteristics should reusable products have so they are used longer? Six participants were invited to start using two reusable products for three weeks: food huggers (used at home, same for all six participants) and an 'on the go' product (two respondents each): a food wrap, a reusable coffee mug, or a reusable bread bag. Physical diary booklets were used to qualitatively collect the users' experiences with the test products. After three weeks, a follow-up interview was held with each participant. The paper concludes with a set of propositions to make repeated usage more likely. A distinction was made between barriers related to the product on the one hand and barriers related to the existing routines of the user on the other hand. The main barriers to using the food huggers are related to practicality, while planning and existing routines influence the regular use of the 'on the go' product the most. In general, according to the users, reusable products should offer the same or more benefits as their single-use counterparts. Future studies should focus on longer usage periods with different types of products such as intimate-hygiene-related products, and other means (such as digital diaries) could provide more time-specific and rich data.

## Introduction

Plastic pollution is an enormous environmental problem which contributes to water, soil, and air contamination, and has a strong negative impact on wildlife and potentially on human health (Cox et al., 2019). As a result of the European ban on several single-use products, the demand for good, reusable alternatives has increased (European Parliament, 2019). Since reusable products need to be more durable and qualitative than their single-use counterparts, they usually consist of more material and have higher energy and water usage during the production phase (Herberz et al., 2020). Therefore, most of the environmental impact is highly dependent on the consumer and their repeated usage of the product. There will only be an environmental gain when the product is used beyond its breakeven point, which is the number of reuses needed for the environmental impact to be equal to the impact of each time using a new single-use product (Fetner & Miller, 2021).

Next to the acquisition of the reusable product, it is important that users change their behaviour accordingly by integrating new habits into their daily routines. Existing habits influence people's behaviour, which often makes the new habit or routine harder to implement (Verplanken & Orbell, 2003). Consequently, understanding the enablers and barriers of repeated reuse is key to designing better reusable products (Kunamaneni et al., 2019). A substantial amount of research has been done on reusable products such as the comparison with single-use products in terms of ecological footprint (Fetner & Miller, 2021), the assets and liabilities of these products (Greenwood et al., 2021) and the use or purchase of refillable products (Kunamaneni et al., 2019). However, the underlying causes or motives for the repeated use of reusable products, or the barriers that impede long-term adoption have not yet been widely investigated.

In this study, we focus on potential thresholds that prevent repeated usage of reusable products. We want to create a better understanding of the enablers and barriers that come up during the first weeks of usage of a newly introduced product, and how these products can be implemented into daily routines.

## Methods

We did a qualitative diary study (n=6) to explore real-time self-reported behaviour over a period of three weeks, investigating enablers and barriers to the repeated use of newly introduced reusable products. The diary study method enabled us to acquire in-depth data and descriptions with rich in-context information on the user's thoughts and feelings towards the products (Berg & Düvel, 2012). Besides this, they capture the experience of the participants as realistically as possible and in a real usage scenario.

Each participant used one 'at home' product, namely food huggers (reusable plastic wraps to put on used fruits or vegetables to keep them fresh or to cover cups or plates), and one 'on the go' product: a food wrap (to wrap sandwiches), a reusable coffee mug (foldable silicone coffee cups with a polypropylene lid and holder), or a reusable bread bag. We selected the products because they are relative new and not yet adopted by the majority of the population. The participants were not familiar with the test products beforehand. We selected them based on their willingness to use reusable products without using them already. To be eligible for the study, they had to have the single-use equivalent of the test products in their daily routines as well, indicating use for the test product, as well as providing a reference point during the study.

We divided the participants into three groups of two, based on the above-mentioned requirements (table 1). Since gender was not part of the requirements, we unintentionally selected only female participants, age ranging from 25 to 54 years old, with medium income.

Physical diary booklets were used to avoid the thresholds of new digital platforms. Each respondent received two booklets, one for each product, and was requested to track their experiences with the products daily. After one and a half weeks, a short check-up conversation was held with the participants to discuss how it was going and whether they had encountered any problems.

| Group | Requirements |
|---|---|
| Bread bag + food hugger (1a, 1b) | - Often goes to the bakery<br>- Currently uses a regular disposable bread bag<br>- Uses plastic wrap (occasionally) to cover food |
| Coffee cup + food hugger (2a, 2b) | - Goes to get take-away coffee regularly (at least 2x/week)<br>- Doesn't use a reusable cup yet<br>- Uses plastic wrap (occasionally) to cover food |
| Food wrap + food hugger (3a, 3b) | - Gets a sandwich regularly (at least 2x/week)<br>- Doesn't use reusable wrap yet<br>- Uses plastic wrap (occasionally) to cover food |

**Table 1. Participant requirements.**

The booklet contained questions such as 'When did you use the product?', 'What did you find positive and negative about the use?', and 'Why did you choose to use the single-use version instead of the reusable version?'. The participants were also asked to take photos during their use of the product. After three weeks, the diaries and photos were collected, and a semi-structured follow-up interview was held with each participant to question the overall products' experiences and potential improvements. The interviews lasted around 45 minutes. The data from the booklets and interviews were analyzed descriptively, looking for similarities and contrasts in the experiences of the participants.

## Results

### *Food huggers*

The food huggers were mainly used to cover and preserve fruits and vegetables. Five out of six participants indicated that they were very convenient for this and that they could be used quickly and easily. Several participants also used the food huggers to cover jars without lids, but they were considered less suitable for this purpose.

Identified limitations are related to (i) **fit**: although three sizes were available, sometimes none of the food huggers would be the right fit. According to five of the six participants, the food huggers were too small which limited their use. This is related to (ii) **adaptability**: the food huggers do not easily stretch to fit over slightly larger objects. This became easier with some practice. The sturdiness of the material also leads to the (iii) risk of **squashing** soft fruit or vegetables. Lastly, (iv) one participant indicated that the preformed **shape** was not very convenient.

The participants that put the food huggers in the dishwasher, found that almost every time **dirt or water** remained in the folds of the product (figure 1), and the material would feel sticky. The participants that cleaned the food huggers **by hand** said they were easy and quick to clean. One participant indicated that she turned the food huggers inside out to clean them, which would work quite well. Difficulties were also encountered in **drying** the food huggers because they could fold by themselves. Therefore, two of the participants indicated that they had doubts about the **hygiene** of the product when it would be used for a long time.

**Figure 1. Food huggers after cleaning.**

Four participants decided they would continue to use the food huggers, in **combination** with reusable jars, since the food huggers cannot be used for all applications. Two participants would replace all cling film with the food huggers in the future. Two participants were not convinced after the research period and indicated that they would not continue using the food huggers. One of them even switched back to cling film during the study even though we specifically asked not to. For her, the product was not efficient enough and using it took too much **effort**. Another stressed the fact that the food hugger fitted quickly in her daily routine: it was easier to get it out of the drawer than the cling film. In addition, the food hugger was ready to use, the plastic wrap needed extra effort to cut into the right size.

*Bread bag*

Positively, (i) the roll-top closing system was immediately **clear** for both participants and **easy to use**. (ii) The bread inside the bag was perceived to stay **fresh** longer compared to a normal paper bag. (ii) Once closed, a convenient **handle** for carrying the bag is created. (iv) The **cleaning** of the bread bag was considered easy and time-efficient by both participants. The inner bag could be put out of the outer bag to remove the remaining breadcrumbs. However, participant 1b would have liked a different material, because in her opinion the current **material** does not allow for thorough cleaning with water.

Identified barriers for the bread bag are (i) buying more than one bread at a time, for example for a family of five, or having unfinished bread at home requires an **additional** bag, which was not provided. (ii) Both participants found the bag **too small** for both homemade bread and bread from the store or bakery, where not every kind of bread would fit in the bread bag, as shown in figure 2. (ii) **Social acceptability**, especially in the bakery, was also noted as a concern, as well as (iii) **forgetting** to take the bag and implementing it in the existing routine.

**Figure 2. The loaf is too big for the bread bag.**

After three weeks, participant 1b stated they would not use the bread bag anymore in the future, because there were too many inconveniences and she did not feel comfortable yet bringing it to the bakery. Interestingly, she started using it as a **lunchbox** alternative instead, indicating an opportunity for multifunctionality. Even though the bag was not perfect, participant 1a was still enthusiastic about the bread bag and committed to using it in the future as an addition to single-use paper bags.

*Coffee cup*
Participant 2a often goes to take out a coffee, for which she uses a single-use cup. Participant 2b was planning to buy a reusable cup to win time in the morning and drink her coffee during her drive to work (figure 3).

**Figure 3. Coffee cup in car.**

Positive aspects are (i) the **look** of the cup and (ii) the fact that it is **sustainable**, which gave them a boost for using it. Also, (iii) the **cleaning** of the product was perceived as relatively easy, although some stains on the lid would sometimes be hard to remove.

Identified barriers are (i) that the cup does not keep the coffee **warm** very long and (ii) the heat sleeve is not sufficiently **heat resistant**, thus making it hard to hold the cup when the coffee is still very warm. (iii) It can be a challenge to always **anticipate** the possibility of having a coffee that day, and thus not **forgetting** the cup at home. Other thresholds are (iv) the practical ease of **folding** the cup and (v) the inconvenient opening in the **lid** to drink from. Another remark was (vii) that the plastic cup gets **stained**, strengthening a participant's concern that chemicals from the plastic could leak into the coffee.

*Food wrap*
Both participants were pleasantly surprised by the product. They liked the (i) **looks** of the product and found it overall very (ii) **practical** in use. A big perk of the product is that it also serves as a (iii) **placemat** (figure 4). Both participants also received (iv) **positive reactions** from colleagues when using the food wrap, stimulating them to use it. (v) The food wrap was perceived as very easy to clean by both participants because of its flat surface and material.

On the other hand, both participants were scared that, because it is a relatively unknown product, they would (i) **burden** the people of the bakery with extra time to figure out its use, especially when it was already crowded at the store. Besides this, (ii) the food wrap does not completely **protect** its substance, and (iii) does not prevent potential **leakage**.

**Figure 4. The product can be used as a placemat.**

During her participation in this three-week trial, participant 3a did not use the single-use alternatives even once, which in this case are plastic wraps or aluminium foil. Participant 3b needed more time to get used to the food wrap, eventually storing it in the office to prevent forgetting it at home and cleaning it immediately after use. For both participants, the food wrap successfully replaced the single-use variant, and both are willing to continue using it in the future.

## Discussion and conclusion

*Limitations*
The research method made the success of the study dependent on the motivation of the participants since a large commitment was requested. Besides this, sometimes participants failed to fill in the diary or filled it in afterwards because they forgot or did not have time to do so in the moment. Hence, it was very important to conduct the follow-up interview to fill in missing information. Because of the limited participants (n=6), the results cannot be generalized to the broader population.

### *Conclusions*

To answer the main research question 'What are the thresholds that complicate the use of alternatives of single-use plastics?', a small-scale research was done (n=6) using four reusable products. Based on this research, we can formulate the following propositions:

Proposition 1: twelve decisive factors can be distinguished that determine whether or not someone keeps on using a certain reusable product: fit, ease of use, maintenance, multifunctionality or added value in comparison with the single-use product, the influence of (social) environment, space occupation, need for thinking in advance, quality, product affordance, time occupation, safety and health perception, and aesthetics.

Proposition 2: Two types of barriers derived from the participants' experience were distinguished: a) Barriers related to the **features of the product** itself, i.e. adaptability, size, ease of use, ease of cleaning, multifunctionality, space occupation, quality of the materials, self-explanatory, healthiness, and attractivity, and b) barriers related to the **habits and routines of the user**, e.g. the need to plan in advance, the time consumption, or when they are not comfortable with reactions of people when using the product.

Proposition 3: On-the-go products often require additional conscious decision-making like planning to successfully use them. As proven by the increased usage of the products during the test period, integration into existing habits or forming a new one is essential to fade away this cognitive task. Putting the products in a visible, convenient place could help to fit them into the existing routine.

Proposition 4: In conclusion, it can be said that for reusable products it is important that they offer the same or higher benefits (cost, comfort, usability) as the single-use variant.

### *Future research*

The products that were selected for this study are all food-related and assume sole ownership. It would be interesting to compare the results with other types of reusables, such as those related to intimate hygiene (e.g. menstrual cups or reusable diapers), or different reuse models (e.g. return).

The diary study method is an effective and intuitive way to conduct user insights, but it is also important that it is sufficiently prepared. Participants have to be reminded on a regular basis to ensure that enough information can be collected after a long period of time. Future research should consider the usage of digital diaries to track the participants more closely and in real-time (especially for 'on the go' products), and over a longer period.

# Can you fix it? An investigation of critical repair steps and barriers across product types.

**Aisha Susanne A. Hjorth Nielsen[a], Linda Nhu Laursen[a], Christian Tollestrup[a]**
a) Aalborg University, Aalborg, Denmark

**Keywords:** Product repair; Repair café; Product types; Repair steps; Repair barriers.

**Abstract**: Effective repair practices are identified as a key strategy to prolong product lifetimes. This study examines how repair practices differ across product categories at repair cafés in Denmark. 370 incoming products are divided into four categories: static, mechanical, electrical, and electro-mechanical, and are then evaluated based on fixers' previous repairability experience. Each type was found to have varying critical repair steps, barriers, reparability likability, and tools needed. Overall, this study highlights the importance of understanding critical repair steps and barriers to promote sustainable consumption practices and may inform future product design and repair support initiatives.

## Introduction

One way to reduce the environmental impact of consumer goods is through effective repair practices, as they are viewed as a key strategy to help prolong the lifespan of products and materials (Cooper, 2010; Bakker et al., 2013; Hernandez et al., 2020; van der Velden, 2021; Laitala et. al, 2021). However, research shows that repair competence is one of the main barriers to the repair effort (Laitala et. al, 2021).

Recent studies have found that in order to enable product repair, repair needs to be made assessable, e.g., the design needs to enable the consumers to care for and repair the product themselves (Ackermann et al., 2018; Park 2019); the product needs to enable pre-steps such as diagnostics, assessing, and opening with standard tools, as well as repair steps, which may include tools, skills, and the availability of spare parts (Charter & Killer, 2014; Cooper & Salvia, 2018; Mashhadi et al., 2016).

Repair cafes have emerged to address this problem of product overflow and provide expertise to overcome consumer barriers (Graziano & Trogal, 2017; (Dewberry et al., 2017; Diddi et al., 2019; Moalam & Mosgaard 2021; Yazir-lıoğlu & Doğan, 2021). Consumers are referred to as bringers (Madon, 2022), and seek help from experienced volunteers to gain knowledge and repair their products and avoid them ending up in the landfill (Bracquené et. al, 2018). Previous studies have explored the varying expected lifetimes across product categories (Cox et. al., 2013) and how inheritance behavior differs across product categories (Frahm et al. 2022).

Research of how repair practices differ across product categories at repair cafés has to our knowledge not yet been studied.

### *Product categories*

The repair café experiences a big inflow of products, research shows the most common categories repaired at repair cafés are: Small Kitchen Appliances, Household Appliances, Lighting, DVD/CD Players, and Clothing (Charter & Kieller, 2016). These products are often older with differing properties (Van der Velden, 2021), which can be classified as 1) static, 2) mechanical-, 3) electrical, and 4) electro-mechanical products (see Figure 1, adding on Maestri & Wakkery's (2011) three definitions of an object type including an additional para-meter static.

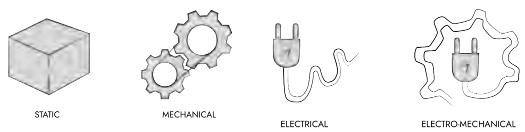

**Figure 1. Product types (own illustration, building on Maestri & Wakkery, 2011).**

**Static**: Products that do not involve machinery or movement, such as chairs, interior objects, and clothing items.

**Mechanical products**: Products that are powered or operated by a machine or tool and are related to movements, such as bicycles, hand tools, or antique or analog watches.

**Electrical products:** Electrical products are related to or operated by electricity and include a diverse range of complexity, from simple electronic products like lights, chargers, or hair straighteners to more complex components like radios, PCs, sound systems, and TVs.

**Electro-mechanical**: Products that combine mechanical and electronic systems, including CD players, coffee machines, kitchen machinery, and powered tools.

*The repair steps*

When products are repaired, they undergo certain repair steps, identified in a recent study (Braquené, 2018, see Figure 2). The five steps include: 1) Product identification, retrieving information about the product and model. 2) Failure diagnostics, locating the cause of problem or fault(s). 3) Disassembly & Reassembly, opening the product, and ease of reassem-bling. 4) Spare part replacement, finding and changing the spare part and 5) Restoring to working condition, either resetting the product or performing necessary handling to restore it. In this study, we investigate if there is a difference in the repair practice depending on the product types (i.e., groups of products) and if the critical repair steps differentiate based on certain barriers or characteristics.

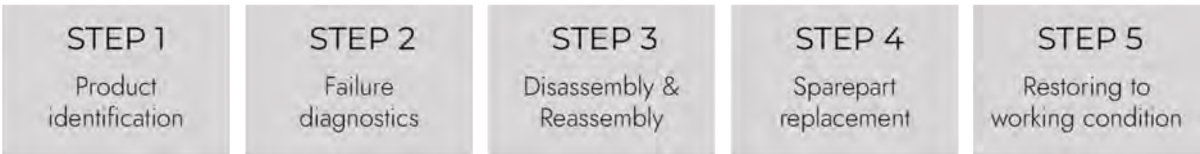

**Figure 2. Repair steps, from Bracquené, 2018.**

## Methodology

A mixed-methods study has been conducted to examine repair efforts across product cate-gories. This involves qualitative and quantita-tive data collection and analysis. 370 products were gathered using convenient sampling gathered from three Danish repair cafes. These three cafés represent 1) a big city (in Danish context, > 300.000 people), 2) a smaller city (>20.000 people), and 3) the countryside (> 3.000 people). In addition, 16 semi-structured interviews and 38 hours of participatory observations were conducted in the native language to investigate the repair process from both the volunteers' and objective perspectives (Kvale & Brinkmann, 2015; Brinkmann & Tanggard, 2020). All three data methods were used to ensure a legitimate data pool and triangulate and validate findings.

## Analysis

In the study, we investigate the repair success and critical steps that differ across the four product types. Previous research has indicated that some product design features can facilitate different repair processes (Mashhadi et al., 2019). *Figure 3* shows the percentages of successful repairs for each category. The data suggest a **connection between repair success and product types,** and the following discussion relates the critical repair steps to characteristics that differ across each product type.

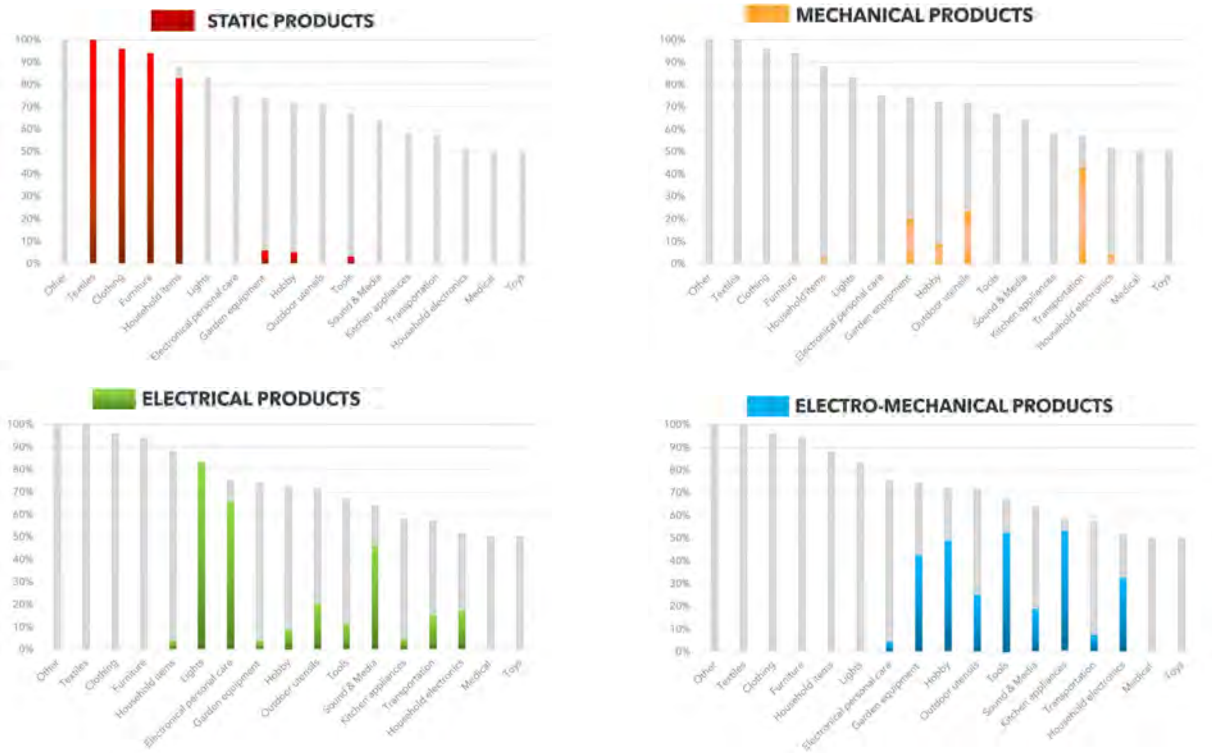

**Figure 3. Percentages of repaired products within 17 categories. Static (red), mechanical (orange), electric (green), and electro-mechanical (blue). Categories with >5 products are not included (Other, Medical, Toys).**

*Static products*

Regarding the success rate of static products, the study found that **97% of all static products are repaired.** This could indicate that these products are submitted to lower complexity and that the repair cafés have sufficient skills to repair them. These categories are *Textiles, Clothing*, *Furniture,* and *Household items,* such as blankets, cushions, clothing, frames, and chairs. Through participatory observations, it was observed that static products have product features that are easily decoded by consumers, making them easier to figure out how to repair. As Lefebvre et al., (2018) found, people are more inclined to repair items that they perceive to be easy, which then can turn into gained skills that can be transferred to other items, with static elements. The tools required are standard tools, glue, paint, and cleaning supplies.

The most **critical step** in the repair sequence seems to be **the assessment** for static products, which is located under the **2. Step: diagnostics.** The most important factor related to the assessment, was found to be: "*Can I get the product to the desired level of working?".* This is because the primary function has become insufficient, hence needing repair.

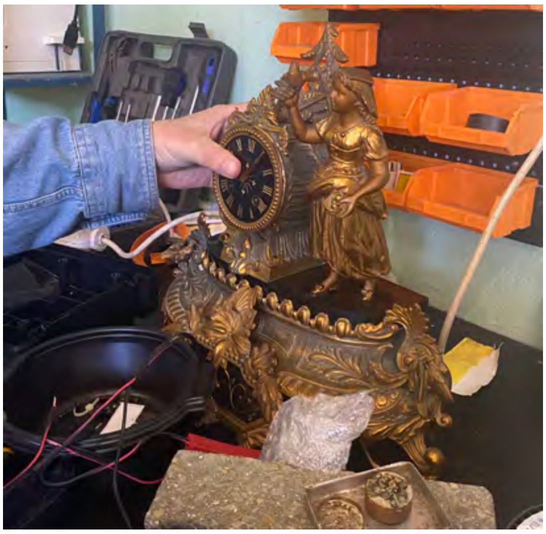
This seems to be related to the product's aesthetic value; if the fixer believed in their skills and ability to restore it to the desired level. This is, for instance, related to material quality, pattern, seam work, or generally handcrafts-manship. Aspects directly related to **the final step 5**, restoring to working condition. This is also present in static components connected to other product types. For instance, electrical speakers encased in textiles can be perceived as a barrier. Despite having electrical issues, the textiles and aesthetic appearance becomes a hindrance, as the fixer evaluates the reattachment of the textile to be unsatisfactory, ending the repair. In such a case, the fixer would recommend the bringer seek restoration expertise from professionals.

Based on the high reparability rate, easy decoding of repair steps such as identification, product faults, and how to retrieve or create spare parts, the authors suggest a start in the repair career with static products. This is applicable for both new fixers and users seeking help, as these products can help create positive repair attempts resulting in confidence that help prompt further repair in more complex products.

### *Mechanical products*

Related to mechanical products**, 61%** of them were repaired. The repair attempt seemed to be highly related to the fixer's skills, expertise, and how frequently the product functionality was present. Many of the found mechanical products were older, such as old cameras, typewriters, etc., or tools and garden equipment. A decreasing product type, as newer mechanical products, have some connection to electricity. Mechanical products have a high complexity related to product architecture. This emphasizes that the **disassembly and assembly, step 3** is a critical element in the repair, as it ensures that complications are met in the repair effort, both in assessing faulty parts or cleaning/maintaining internal parts. Complex architecture has the disadvantage of creating additional faults in the disassembly. "*It is like fixing a car, every gear needs to fit perfectly for most mechanisms to work. It requires precision and product knowledge, so I get not everyone is up to tackle that"- Mechanical engineer.*

It was found that visibility of the mechanisms leads to greater success in the repair, as observed in bikes or wall clocks. The inability to view the mechanisms creates issues; for instance, mechanical toys, designed to limit the risk of choking hazards, disabled the fixers from opening the toys, much to the dislike of the anxious grandmothers and children hoping to bring home the best play buddy. Similar issues arose from the lack of cleaning of accumulated oil in mechanical products, requiring careful de-clogging and polishing, a procedure not many fixers found amusing. A modular structure, with easy accessibility and overview as well as utilizing standardized parts, would be preferable. However, **the most critical** was **step 4 the retrieval of spare parts**, as these provide difficulty in finding the exact component as seen in Figure 4, where an old mechanical clock was stored at the repair café, waiting for the day when a similar gear would be collected from a discarded product. In some cases, fixers created a similar part, by welding scrap pieces together. However, a welding machine is not a common tool at a repair café.

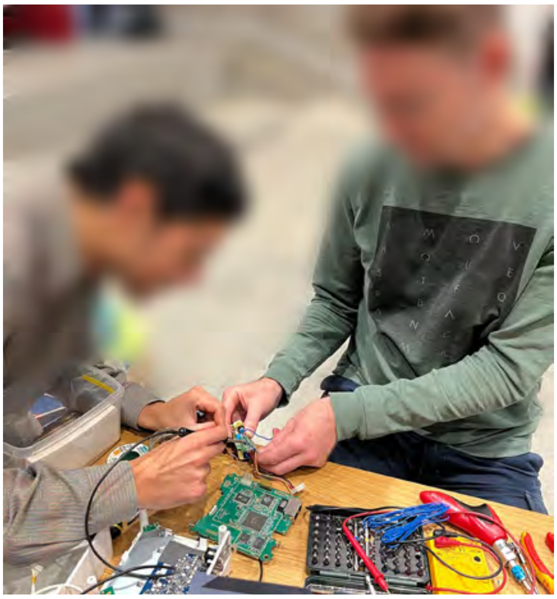


**Figures 4. Mechanical watch, unable to retrieve spare parts.**

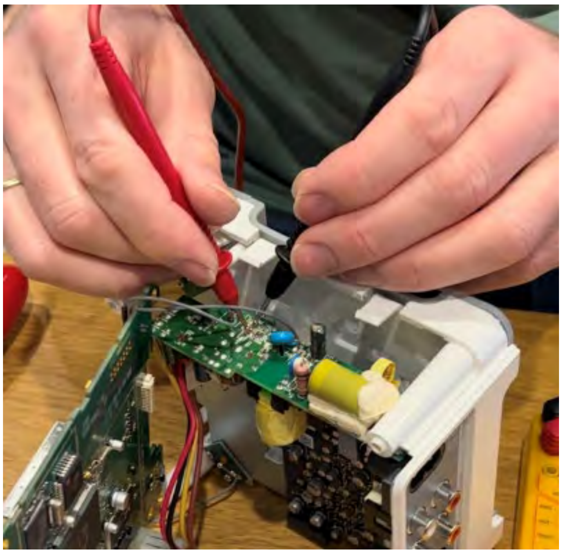
### *Electrical products*

For electrical items, **67%** of the incoming products were repaired. Due to the wide range of complexity in electrical products, **the diagnostic step (2) was critical** as there are often no indicators of what aspects are faulty. Repair fixers look for burnt parts or connections to increase the processes, however, highly complex products often still need a longer diagnostics process, such as a *Sonos* amplifier, where three PCB boards were identified to find the fault (Figures 5 & 6). In this instance, two volunteers spent over two hours trying to locate a potential fault. *"I am trying to run power through several parts of the system, to locate which part is not responding"* – Radio engineer. This shows a barrier, as repairing electrical products requires knowledge related to power theory and tools such as multimeters, soldering iron, and secondary batteries. This constitute a high learning curve and a potential risk, which has previously been identified as a risk on the consumer's side (Terzioğlu, 2021). Further repair barriers are related to lithium batteries, a power source extremely common in wireless products, unfortunately extremely difficult to repair, as skill level exceeds most fixers.

A secondary critical step was found in cheap electrical products, where **disassembly, step 3**, often was impossible, due to stamping or gluing in the production method. Expensive products faced similar issues, as screws or connections were purposefully hidden to create a more simplistic look. The lack of accessibility in the constructions also posed another barrier, as accumulation of dust creates overheating causing the electrical components to fail, which is present in products like TVs.



**Figures 5. Two fixers repairing a Sonos amplifier.**

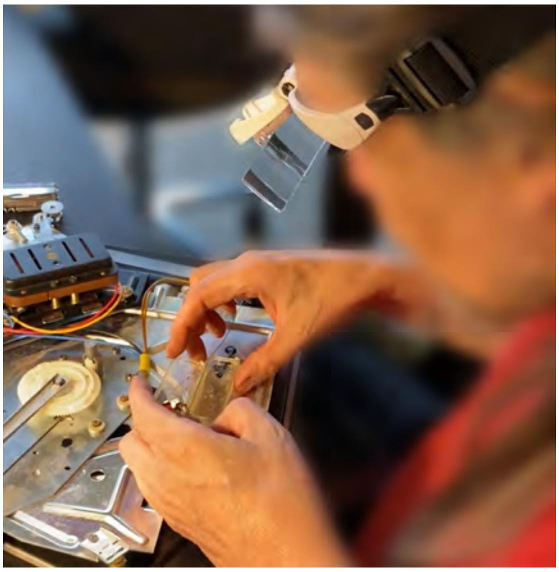


**Figures 6. Close-up of diagnostics process on three PCB boards.**

*Electro-mechanical products*

Related to electro-mechanical products**, 64%** were repaired. The duality of the product type creates increased complexity resulting in collaborative repair, between two or more fixers often with specialized tools (see Figure 7). The **most critical step, Step 2 diagnostics,** were found to be the most critical step as these products are often subjected to secondary faults caused by exhaustion of the internal motors. For instance, this is present when blending frozen goods, cutting down a tree, or when drilling into a wall. The original blockade or exhaustion causes overheating, leading to the failure of the electrical components.

"*It is often difficult to know what part is broken… you often assume which part is potentially broken, or you locate the area of the fault and try to fix it, but the machine is still not responding. So, either it didn't need that first repair, or it is a case of multiple ghost faults. Hard to know."* – Electrician.



**Figures 7. One fixer in collaborative repair. Electrical focus with specialized glasses. [An old B&O record player]**

If the faults were not related to issues related to the diagnostics, it was found to be connected to **step 3: maintenance.** The lack of product care and the presence of dust and liquid showed to be important factors in the repair. Many electro-mechanical products were subjected to either oil, water, petrol, or ink and had some issues related to clogging. For instance, ink in printers can cause the cartridge to clog automatically. "*You actually need to print every week for the ink not to dry up… Printing one sheet of paper is cheaper than the automatic cleaning setting in the printer…nobody is aware that by not using your printer, you are purposely ruining it... happens to a lot of products*" – retired engineer.

Products with old liquids can be difficult to clean once they have solidified, often requiring chemicals and additional space, something that not all repair cafés possess, as they are not in their own accommodations (see Figure 9). Dust, which is present in CD players, angle grinders, and especially vacuum cleaners, also poses a significant issue as it fills the space needed for ventilation, causing a component shutdown – often a recurring problem even if fixed. Both steps 2 and 3 are related to tear and wear, which increases over time.

**Figure 9. Declogging of a steamer**

| **Product category** | **Specifications** | **Critical repair steps**<br>*Assessment, an aspect placed in step 2, has been excluded from the general diagnostics step and will be referred to as *Step 0, assessment*. |
|---|---|---|
| Static | **Complexity:** Low<br>**Tools:** Standard tools, Glues, paint, cleaning equipment<br>**Repair**: 97% | **Step 0: Assessment.** The fixer evaluates the ability to restore to the desired level of working, which is linked to step 5. (An evaluation of skill level, and expertise in relation to the product) |
| Mechanical | **Complexity:** Medium to high<br>**Tools:** Standard tools, Welder, compression air dusters, cleaning equipment.<br>**Repair:** 61% | **Step 0: Assessment.** Same as static products but influenced by previous experiences and the perceived complexity.<br>**Step 3: Disassemble and reassemble.** Is vital, influenced by product architecture and composition, especially the use of visible or hidden mechanisms. Disassembly can cause further faults when repairing and maintaining gears with the use of oils.<br>**Most critical step: Step 4, retrieval of spare parts**, as mechanisms often require a specific part that needs replacement, which can be hard to retrieve due to the product's age. |
| Electrical | **Complexity:** Medium to high<br>**Tools:** Specialized tools, Multimeter, soldering iron, compression air dusters.<br>**Repair**: 67% | **Step 0: Assessment.** Previous points apply. The range of components and the applicability determine the product's complexity which is influenced by product architecture and aesthetics.<br>**Most critical step: Step 2: Diagnostics.** The complexity requires extensive time, effort, and special tools and confidence to repair.<br>**Step 3: Disassembly, reassembly, and maintenance**. Both cheap and expensive products face issues with either stamping, gluing or hidden screws |
| Electro-mechanical | **Complexity:** High<br>**Tools:** Specialized tools, Multimeter, soldering iron, compression air dusters, glues, cleaning equipment<br>**Repair**: 65% | **Step 0: Assessment.** The product type requires expertise in both electric and mechanical knowledge, limited to a few individuals, often requiring collaborative repair.<br>**Most critical step: Step 2: Diagnostics.** Differentiates from electrical, as these products are often subjected to high impact during usage, resulting in various errors with multiple causes, difficult to determine.<br>**Step 3: Maintenance.** The products are subjected to a lack of maintenance, especially related to liquids, which adds complexity. |

**Table 1. Specifications and critical repair steps across product types.**

## Concluding discussion

The investigation into four product types suggests that there is a hierarchy in repair complexity. Our study sheds light on the critical repair steps across product types, as these pose varying barriers to the repair effort, with the assessment acting as a universal critical barrier (Table 1). Although the repair movement is growing, our study highlights the vital role of skilled volunteers in capturing learnings that are essential to companies and legislators to promote and contribute to future repair-focused product development.

# Love at first sight: Immediate emotional attachment of volunteers in repair cafés

**Aisha Susanne A. Hjorth Nielsen[a], Linda Nhu Laursen[a]**
a) Aalborg University, Aalborg, Denmark

**Keywords**: Immediate Emotional Attachment; Emotional Attachment; Repair Cafés; Repair; Fixer Community.

**Abstract**: Repair cafés have been identified as a key approach for addressing the issue of decreasing product lifetimes (Charter & Keiller, 2014, 2016; Bakker et al., 2014). These cafés offer free repairs of products by volunteers, which extends their lifespan. In this study, we examine how emotional attachment of repair volunteers affects their inclination to repair products. Through 20 semi-structured interviews and 38 hours of participatory observations with repair volunteers from repair cafés in Denmark, we identify 11 factors that trigger immediate emotional attachment of repair volunteers. Nine of these factors are consistent with existing literature on emotional attachment, such as personal gain, pleasure, and group affiliation (Mugge et al., 2008). The study also identifies two factors in a new category related to socialization that influences the likelihood of product repair. Our findings emphasize the importance of emotional attachment, not only driving repair behavior among consumers but also among repair volunteers. In particular, we highlight how the social aspects can drive repair behavior among volunteers.

## Introduction

Today, products have become increasingly difficult to repair (Fachbach et al, 2022). Product repair often requires various skills and resources (Hernandez et al., 2020). This may lead to a decrease in consumer interest and participation in the repair process (Mashhadi et al., 2019). In fact, for many consumers, a lack of knowledge and skills is the primary barrier to product repair (Scott & Weaver, 2014; Fischer et al. 2008; Dewberry et al., 2016; Cole & Gnanapragasam, 2017).

Repair cafés address the repair barriers and the throwaway culture by enabling repair and reducing the number of discarded products (Pit, 2020; Ames & Rosner, 2014; Charter & Keiller, 2016). The decision to dispose of products prematurely has been shown to be emotional as well as social (Schifferstein et al., 2004; Park, 2019). Repair cafés volunteers can play a vital role by providing the necessary skills, knowledge, and experience to overcome the barriers faced by consumers referred to as "bringers" (Madon, 2022) and help enhance product lifetimes.

According to Cooper and Salvia (2018) and Mashhadi et al. (2019), product reparability is significantly influenced by factors such as ease of use, diagnostic tools, easy opening, and availability of spare parts. Charter and Keiller's (2016) survey of 317 repair cafes across 10 countries found that, on average, 63% of products are repaired. However, volunteer repairers may devote additional time and effort to some products, prompting questions about how they decide which products warrant such extra attention.

Research has been conducted on consumer decisions to repair or replace products (Rosner & Ames, 2014; Scott & Weaver, 2014; Ackermann et al. 2018; Didi et al, 2019; Lefebvre et. al 2018; Terzioğlu et. al, 2021; Laitala et. al, 2021). Studies have shown that products considered worth repairing were perceived as valuable, easy to repair, or had some emotional attachment to the product (Lofthouse & Prendeville, 2018). This is further strengthened by the celebration of each successful repair activity (van der Velden, 2021). Current, research shows how nonprofessional enthusiasts' emotional attachment enhances product care (Yazirlıoğlu & Doğan, 2021), but less is known about the decision-making process of volunteer repair fixers.

*Emotional attachment*
Emotional attachment is defined as a strong emotional connection which users can feel towards a product or brand (Chapman, 2005; Hernandez et al., 2020; Page 2014; Terzioğlu, 2021) and influences the ability to prolong product lifecycles (Mugge et. al 2005; Hernandez et al., 2020). The literature focuses on the reasons why people become attached to certain objects (Kleine et al., 1995; Schifferstein et al., 2004; Schultz, et al., 1989) and highlights four determinants of attachment on the consumer side (Mugge et al. 2008):

• **Pleasure:** A feeling of enjoyment or relaxation that comes from using the product. For instance, a tv, that creates excitement ensuring a return for the user.

• **Self-expression:** The desire to differentiate oneself and express their identity through products. The user is driven by the symbolic value: shape, color, or material. For instance, a Fiat 500 that the user perceives as cute, thereby expressing their own view outwards.

• **Group affiliation:** The need to be connected and associated with others, often related to a specific brand or symbolic meaning. For instance, a wedding ring, showing a connection to a spouse, or a sweater connected to one's fraternity.

• **Memories**: A reminder of a specific event, person, or place, causing a symbolic meaning resulting in people holding on to the product. Memories are strongly associated with nostalgia, and gracefully aging. For instance, marks on a leather jacket are reminiscent of a particular moment.

Currently, literature states how emotional attachment is increased by the time of ownership (Ball & Tasaki, 1992; Ko & Ward, 2011). However, in this study, we focus on 'immediate emotional attachment' – an instantaneous attachment. The study aims to identify the factors that lead to increased (or even extraordinary) repair effort, for example, one volunteer stated: *"Don't worry I can take the product home and see if I can fix it*" - #3.

## Methodology
A qualitative methodology study was conducted at Danish repair cafés to investigate the immediate emotional attachment. This involved 38 hours of participatory observation and semi-structured interviews with 20 volunteer fixers, providing detailed information and prompting further questions about their experiences and stories (Brinkmann and Tanggaard, 2020; Kvale and Brinkmann, 2015).

## Findings
This qualitative study provides insight into the emotional attachment of repair volunteers, which has not yet been explored in the literature. In the following section, we will discuss the findings from the study, which identified 11 emotional attachment aspects within four categories:

*Pleasure*
Three pleasure-related aspects influenced the immediate emotional attachment of volunteer fixers. They are connected to feelings of relaxation and enjoyment that trigger the process (Terzioğlu, 2021):

**1) Tinkering:** Many interviewees expressed interest in tinkering, a characteristic shared by many volunteer repairers (Orr, 1990). *"I have always tinkered with all different kinds of things. I love investigating products."* - #3
Some products ignite an emotional attachment for volunteer fixers due to their curiosity. *"So, I looked at it at home - I looked at it several times, then I called him and said I couldn't repair it… I took it completely apart to see how such a thing is constructed - I've wanted to look at an expensive espresso machine for a long time.*" - #12
This suggests that some products create an emotional attachment, as the perceived repair initiative is already appealing to the fixer and ignites pleasure in the fixer (Pesch et. al, 2019).

**2) Repair difficulty**: The perceived repair difficulty is often perceived as a barrier (Fachbach et. al., 2022; Lefebvre et. al., 2018; Güsser-Fachbach et. al, 2023), and is influenced by the starting point (Terzioğlu, 2021), but for highly educated and technical volunteers, it can be a motivator. For example, a radio engineer started to repair a *Sonos Connect*: a highly technical device that connects several speakers, regardless of the brand, to one another. Due to the complexity of the product, the diagnostics contained measuring every connection of three PCB boards. the fixer was committed to figuring out how to repair it and even asked to take it home to continue working on it. "*I must admit, I have never seen a device like this… Now I am committed to figuring out how to repair this device… it should be easy to fix once having identified the problem, I have looked at almost all connections… I'm positive it will happen; I am at least trying...* - #8.

**3) Repair success:** Success or achievements are an immense driver (Schwartz, 1992) and is expressed through the internal tally counts: "*I take pride in having an almost perfect repair success… this repair café is actually one repair café with the highest success rates in Denmark*". - #9. It acts as a social acceptance within the fixer community, a motivational aspect previously identified on the consumer side (Ackermann et al., 2018), and is a token of repair achievement, demonstrating competence according to social standards (Schwartz, 1992). This influence why many volunteer fixers take great pride in the repairs they perform.

### *Self-expression*

These aspects influence the volunteer fixer's identification with incoming products, causing appreciation of the product on the bringer's behalf. These products create a stronger connection between the bringer and the fixer, and include two aspects:

**4) Brand Loyalty**: Brand loyalty play a role in the immediate emotional attachment between the product and the fixer. The fixers' previous encounters with the brand has been positive, both in relation to specific brands, such as Singer, Bang & Olufsen, etc. As seen on the consumer side, the fixer feels an appreciation of the brand's perceived value, here the use of materials, finishes, and features.

**5) Hobby**: Immediate emotional attachment is seen through the involvement of the fixer's own personal hobbies and interests. One fixer continuously kept bringing the garden equipment home: "*I love gardening and welding and fixing products. When spring comes around, I make sure to come volunteer at every repair café… We share gardening tips and compare sorts".* - #19

During a guitar repair, the fixer discovered a broken connection between the amplifier and the guitar, causing the sound of the electrical guitar to change. The fixer quickly repaired the problem at the café, and afterward, the bringer and fixer had a conversation about product care and music. The shared understanding and appreciation of similar interests resulted in improved care for the product, as the bringer was informed of what to look out for the next time.

### *Group affiliation*

Group affiliation represents the personal aspects of the fixer that influence the perceived status and identity at the repair café. These signify the knowledge, expertise, and skills the fixers have achieved and can contribute.

**6) War stories (past repair successes):** these are successful repair initiatives that become artifacts that circulate and preserve the success of the repair (Orr, 1990). Within repair cafés, some individuals have a reputation for being the best at repairing a specific product type or category due to previous successful repair experiences. For instance, one fixer said: *"When I was young, probably around 10 or 11, my mother had problems with her sewing machine. It did not work, and she was devastated. So, I tried to look at it, at first nothing happened, but then magically I fixed it. I remember how happy my mom and I were. A machine like that was not cheap to get a new of. So, the next time something happened, I would fix it again…. Now I know all ins and outs of sewing machines*"- #2.
These stories can encourage similar repair behavior and influence the emotional attachment of volunteer fixers to repair products. Fachbach et al. (2022) found that past repair experiences lead to self-efficacy and a positive repair connotation (Lauren et al., 2016).

**7) War stories (brand):** The attachment the fixer creates when recognizing the brand and evaluating it based on past repair attempts is influenced by the ease or difficulty of the repair process or the retrieval of spare parts.
*"It is always nice to help restore good quality product like this… B&O has a great service for gathering spare parts, once they (the bringers) know what parts to buy, they can order them online, return them the following week and we will restore it*". - #13

In contrast, volunteer fixers quickly identify cheap products often produced in China, which become negative war stories creating a low probability of repair. When these products are presented for repair, the fixer may state that the repair will be more expensive than the initial price of the product, resulting in non-repair. Research suggests that consumers maintain early imprinted preferences for brands for the rest of their lives, which may also apply to volunteer fixers (Lambert-Pandraud & Laurent, 2023).

**8) Stewardship:** A parameter of material appreciation such as knowledge related to time, production, resources, and skills can influence the probability of repair, specifically with products appealing to the fixer's stewardship, which is the inclination to see the value and potential in materials (Scott & Weaver, 2014). These parameters appeal to the fixer's deontology rather than the green self-identity (Barbarossa et al., 2017). In the case of a product not being repaired, fixers tend to reclaim the salvageable parts and utilize them for other or future broken products, which can be seen as an act of creativity (Maestri & Wakkary, 2011). *"…, I kept the subwoofers, they were fully working, it would be stupid to throw them out… and then by some time I had built a new speaker…"* -#16

*Memories*

Aspects related to the fixers' own interpersonal memories and experiences related to the objects; also include past repair experiences.

**9) Own memories:** Fixers' own memories related to persons and places can contribute to an immediate emotional attachment to a product. *"I like fixing trinkets; they remind me of my wife – she has a million small quirky things that sometimes need fixing".* - #6

These memories are often highly related to the nostalgic feeling, familiarity, or comfort that the product exudes.

**10) Nostalgia:** Nostalgia was identified as another aspect that contributes to an immediate emotional attachment. Fixers may feel attached to a product that fits into a category of product types that were more popular when they were younger (Lambert-Pandraud & Laurent, 2023). This was for instance an antique record player with a funnel that may evoke excitement: "*Have you heard; we received an old gramophone? I brought it with me home to fix it, I'll bring it next week, and then we will hear the old, probably exquisite sound… it is so cool, I cannot wait".* - #1

*Social aspects*

These aspects influence the fixers through an empathetic response or in the case of anticipating praise.

**11) Transfer of emotions**: due to the sharing of stories between the bringer and the fixer. Previously described as an act of empowerment (Rosner and Ames, 2014). For example, an elderly pair wanted an old mixer fixed, one that belonged to her mother, prior to her passing – clearly an object worth more than its value to the elderly pair. The two fixers immediately helped. "*Mixers are not really my forte, but you obviously want to do what you can with a product like that*" - #15

**12) The Bringer:** The study found that if the bringer demonstrated a commitment to learning and contributing to the repair, it created a stronger social foundation between the bringer and the fixer, which led to the fixer being more motivated to continue with the repair. Additionally, if the fixer simply liked the bringer, it also led to a stronger social connection and increased motivation to repair the product, also driven by potential praise. One volunteer expressed this sentiment by saying,

"*A lady from the community was so thrilled about me potentially fixing her sewing machine, it was my first time looking at one and luckily, I succeeded… You see, the three products over there are waiting in line for me to fix them…."* - #17

| 1) Pleasure | 2) Self-expression | 3) Group affiliation | 4) Memories | 5) Social aspects |
|---|---|---|---|---|

**Table 1. Aspects related to immediate emotional attachment.**

## Conclusions

This study investigated how emotional attachment influences the decision-making process of volunteer fixers at repair cafés when repairing products. The study identified eleven aspects that contribute to a seemingly immediate emotional attachment, causing increased incentive to repair among volunteer fixers. These influence the likelihood of prolonged repair efforts. Nine of these fit the four determinants of previous literature, on the consumer side. Two additional belong to a new social aspect category. These indicate or prompt the volunteer fixer to increase the repair effort.

Further studies could investigate how immediate emotional attachment applies within existing attachment stages (Ball and Tasaki, 1992). The social construct of repair cafés, such as conviviality can strengthen the community's enthusiasm for sustainability (Carrigan et al., 2020), influencing the moral obligation (deontology) related to altruistic character traits.

# Promoting sustainable consumption in online shops through information on reparability

**Marja Lena Hoffmann[(a)], Ivana Trajanovska[(b)]**
a) Technical University Berlin, Berlin, Germany
b) Berliner Hochschule für Technik, Berlin, Germany

**Keywords**: ICT, Repairability, iFixit, French Repairability Index, Sustainability labels, E-Commerce

**Abstract**: Electrical and electronic equipment (EEE) has multiple social and environmental impacts throughout its lifecycle and remains one of the fastest-growing waste streams in the European Union (EU). As many sustainability issues emanating from electronic products occur during the production or disposal phase, extending the life of products has great potential to reduce their environmental impact. Studies show that consumers are interested in repair options. However, for many electronic devices such as information and communication technologies (ICTs) these intentions are not reflected in actual repair data. Indices such as the French Repairability Index and the iFixit Index assess the repairability of EEE. In recent years, customers have increasingly purchased products online, which allows online retailers to play an important role in influencing consumer decisions. While several studies have examined the repairability of ICTs (Bracquené et al., 2021; Cordella et al., 2021) and the environmental impacts of repair and reuse practices compared to EEE replacement (Bovea et al., 2020), there is little research on the visibility of repair information at the point of sale in online stores. In addition, there is little knowledge on the availability of high-reparability products in online stores. Our study aims to address these research gaps by i) investigating what repairability information is displayed to customers in online stores, ii) investigating which products might contain credible repairability information when matched with their respective ratings in repairability indices.

## Introduction and theoretical background

To mitigate climate change and prevent global temperature rise from exceeding 1.5°C, all sectors must reduce their emissions (IPCC, 2022). An increase in emissions and the waste stream resulting from information and communication technology (ICT) devices such as smartphones, laptops, and tablets can be observed. Several studies have found that many sustainability problems associated with electronic products arise during their production phase and that therefore, extending the life of products holds great potential for reducing the environmental impact they cause. For example, Cordella et al. (2021) evaluated different scenarios for extending the replacement cycle of smartphones through reparability. They found that even when emissions generated during repair (e.g., due to spare parts) were considered, overall emissions decreased. A study by the European Environmental Bureau (EEB) found that extending the lifespan by one year could save 1.6 million tons of $CO_2$ per year for notebooks and 2.1 million tons of $CO_2$ per year for smartphones by 2030 (EEB, 2019). In the meantime, the issue has also made it onto the political agenda. The European Commission unveiled a new Circular Economy Action Plan in March 2020 and announced a Circular Electronics Initiative to promote longer product life, for example through regulatory measures for electronics and ICT, including cell phones, tablets, and laptops, under the Ecodesign Directive. In addition, the European Commission recently published the "Right to Repair" proposal as part of the Action Plan. This proposal aims to promote repair as a more sustainable consumption option that contributes to climate and environmental goals under the European Green Deal (European Commission, 2023).

Research shows that consumers are interested in repair options. In some surveys, European participants say they would rather repair products than buy new ones (77%) ((European Commission, 2022)), while other statistics show that the actual repair rates of electronics, especially consumer devices like smartphones, is much lower. However, for many electronic devices such as smartphones, these intentions are not reflected in actual repair data (Zhilyaev et al., 2021). In sustainability research, this phenomenon is often referred to as the intention-behavior gap. The intention-behavior gap has been examined in many studies (ElHaffar et al., 2020).

One factor is referred to as information complexity. Information complexity can be characterized by objectively determinable factors such as the amount and variety of information, its rate of change, and its syntactic and semantic levels, and as an exogenous factor of information behavior, it directly affects consumers' use and evaluation of information (Katz, 1983). Information complexity is threefold (Schlaile et al. 2018): (1) companies often have an information advantage (information asymmetry), (2) the reliability and trustworthiness of information is often difficult to assess, and (3) all relevant information can rarely be viewed simultaneously in the consumer decision-making process (information overload). To cope with information complexity, sustainability labels have been established to promote transparency and trust in sustainability-related product attributes and to facilitate the assessment of a product's sustainability performance (Majer et al., 2022).

In the case of electronic products, one of the most important sustainability attributes is their repairability and thus the life time of the product. However, studies have shown that consumers face challenges when it comes to information on the reparability of products. One possible source of information on the repairability of an electronic device is reparability indices, in particular the iFixit index and the French reparability index.

For the iFixit index, products are disassembled and their repairability is evaluated based on a set of criteria. A score of zero means the product is not repairable, and a score of ten means it is the easiest to repair. These ratings are currently available for laptops, smartphones, and tablets. In 2021, the French government introduced the French Repair Index (FR index) for a large number of electronic devices. This legislation is a milestone as it brings the issue of repairing mobile phones, kitchen appliances, and other electronic devices significantly to the forefront. Similar to the iFixit index, the French repairability index assigns each device a score between 1 and 10; the higher the score, the better the device is to repair. These indices are still being developed further, but already give consumers an impression of the potential to extend the life of a device through repair. However, how visible is that information to consumers when they purchase digital devices? Many purchasing decisions are made in online stores.

Regarding the availability of credible sustainability information at the point of sale in online fashion stores, studies found that while many labels for textile and clothing products are displayed, only a comparatively small percentage are actually third-party sustainability labels and thus credible (Gossen et al., 2022). The study at hand focuses on the availability of information on the reparability of ICT. In addition, this study aims to evaluate what information on the repairability of products could be given if online stores displayed the rating of each product in external repairability indexes. Therefore, this study will answer the following research questions:

1. **What reparability information is displayed in online stores at the point of sale?**
2. **What credible repairability information might be available if products were matched with external sources of repairability information?**

## Method

To answer the research questions, we are taking a stepwise approach. We will focus on data available in German and French online stores. In Germany, we will evaluate the sustainability information on electronic devices offered by the popular online retailers Otto and Amazon. In France, we will only consider information from Amazon. The data was obtained by scraping products and product information from Amazon and Otto in the period of January-February 2023. We focused on the product categories smartphones, laptops, and tablets because we knew there were reviews from iFixit for them. For Amazon, we scraped products that were marked with any kind of sustainability information. For Otto, we scraped all smartphones, laptops, and tablets and their product information. We then checked whether the products carry a label and, if so, which one. For the German market, it was known in advance that the products were supposed to neither have a score of the FR index nor the iFixit. On the other hand, it is known that Amazon France does not use the iFixit score.

In the second step, we performed Entity Matching (EM). For EM, we trained a model on Web Data Commons, a publicly available dataset used as a service after weekly product extraction. A multilingual Sentence Transformer was used as the base model. The model was trained to match products and their ratings from the iFixit and FR indexes with the corresponding products in online stores. The ratings from the French repairability index were grouped into five categories. Since there are no common product labels, EM was necessary. After matching, we rate the products with the reassigned repairability information. This also allows us to match information from the French index with products in the German market, if it is the same product. In the final step, we divide each index into two categories of 'good' (=>6) and 'bad' (<6) scores. Based on these scores, we assess whether the products offered in the stores tend to have high or low repairability.

## Preliminary Results

The preliminary results show that EM was able to contribute to an increase in information on the reparability of smartphones, laptops, and tablets at all stores. Displaying these values could help reduce information complexity for consumers interested in purchasing sustainable devices. As can be seen in Table 1, both stores in Germany did not display the repairability scores of the products prior to the use of EM. This is an expected result since the FR index is not used in Germany. However, when EM is used to carry over the repairability information provided by iFixit or the FR index, the number increases to 199 for OTTO and 24 for Amazon Germany. For France, the FR repairability index could be found after scarping for 50 products. By using the EM this number increases to 81 products.

**Table 1. Products with a repairability score.**

| | *Otto GER* | *Amazon GER* | *Amazon FR* |
|---|---|---|---|
| *Before EM* | 0 | 0 | 50 |
| *With EM* | 199 | 24 | 31 |
| *Total* | 199 | 24 | 81 |

Figure 1 illustrated the distribution of FR Index scores originally found on Amazon FR, which shows that the majority of products have a mean rating between 4 and 5.9. The highest possible scores (8-10) were found for 9 products.

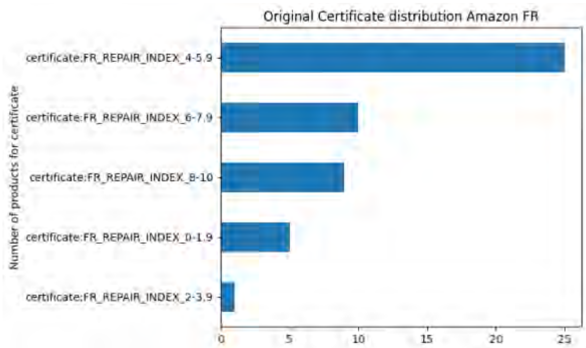

**Figure 1. Original Repairability Scores displayed in Amazon FR.**

Compared to Figure 1, Figure 2 shows which repairability ratings could be added to products by EM in Amazon FR. Combined with EM, the most common repairability rating found is still FR index 4-5.9, which was found on almost twice as many products as the next rating. The third most common value is the iFixit value 1 with over ten entries. This shows that a proportion of the products on offer have low repairability.

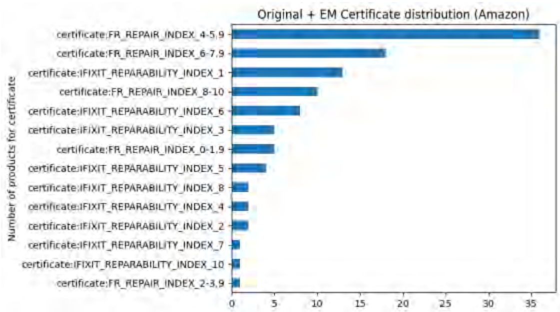

**Figure 2. Original Repairability Scores and EM added Scores of Amazon FR.**

Figure 3 shows the impact of the EM match on the reparability information provided by Otto. The score most often found on Otto in Germany is the iFixit score 3.

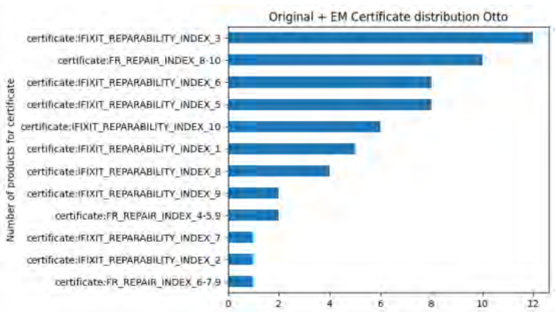

**Figure 3. Original Repairability Scores and EM added Scores of Otto GER.**

The analysis of the type of ratings showed that for both indices, the ratio between products with a 'good' rating (= > 6) and with a 'bad' rating (< 6) is quite evenly distributed overall. For Germany, however, we found that according to EM, more products have a 'bad' iFixit score than a 'good' score, while more products have a 'good' French score than a 'bad' French score.

## Limitations and practical implications

Several limitations must be considered when interpreting the preliminary results of this study. First, the EM is not entirely accurate. Some margin for error may remain with such models. However, we believe that this potential error does not affect the overall direction of the results presented. If these ratings added through the EM were displayed in online retailing, this could influence customers' purchasing decisions. The lack of both positive and negative repair ratings could have a major impact on the future of smartphone, laptop, and tablet repair and thus on the environmental impact of ICT in Europe. In addition, we need to be aware that the online shops assessed, Amazon and Otto, differ in terms of both their markets and the products offered. In addition, all products were scanned and later matched with the EM with repairability ratings for Amazon, while for Otto, only a subset of products was scanned. Therefore, it is not possible to directly compare the ratings for both online stores. Further limitations should be noted for the two repairability scores, which have their own limitations and are assigned different frequencies for products. For example, the FR repairability score is relatively new, while an iFixit score is not given for every smartphone, tablet, and laptop and may have outdated scores in some cases.

## Conclusion

Overall, this study has found that online stores still do not provide sufficient information about the repairability of the ICT they sell. The EM applied has shown that there are already existing sources that provide information on the reparability of laptops, smartphones, and tablets offered in online stores. Providing this information to customers at the point of sale in online stores has the potential to further support customers' sustainable purchasing decisions. We, therefore, advocate that policymakers consider when and where information on repairability is displayed to customers. Initial steps in this direction have already been taken in France. In addition, this study has shown how EM can help fill the gaps of missing information. For further research, it would be important to take a closer look at product-specific ratings and the distribution of ratings within and between ratings.

# The role of experimentation and emergent strategies in developing and scaling circular business models

**Emelie Hultberg**[(a)]
a) Swedish School of Textiles, Department of Business Administration & Textile Management, University of Borås, Borås, Sweden

**Keywords**: Emergent strategies; Experimentation; Circular economy; Scalability; Secondhand.

**Abstract**: The circular economy is an emerging field characterised by complexity and innovation. As such, strategy likely emerges out of practice in a less planned manner. However, this view is largely missing in the growing field of circular business models (CBM) where strategies are assumed to be planned before they are implemented in a rational top-down process. Drawing on an analysis of how a secondhand organisation grew from a single store to become one of few larger commercial secondhand retail organisations, this study aims to illustrate the role of experimentation and emergent strategy-making. The findings, presented as two narratives, show that an experimental approach where strategy emerges from action has played a vital role in the organisation's development. This suggests the need to widen the scope when discussing strategy-making for CBM growth and look beyond tools and metrics used for planning.

## Background

The circular economy, generally described as "an industrial economy that is restorative or regenerative by intention and design" (Ellen MacArthur Foundation, 2013, p. 14), has received increasing attention in recent decades. Governments and business leaders place their hope in a future where circular business models (CBMs) through circular practices and technologies provide solutions to current environmental, and to an extent, social problems. To fulfil this future, CBMs need to be scalable (Ellen MacArthur Foundation, 2017; European Environment Agency, 2019). That is, they need the capacity to formulate and successfully implement strategies that make them grow in size and scope to displace linear consumption and make circularity mainstream. However, as an emerging field, predicting how a circular future would look is both complex and surrounded by uncertainty (Bauwens et al., 2020) which complicates strategic planning.

Yet, CBM literature often takes a rational perspective on strategy formation and implementation where it is assumed that strategies are (and should be) planned before they are implemented in a rational top-down process. This rational approach can even be found in research that highlights the need for experimentation in the transition from linear to circular business practices (e.g. Hofmann & zu Knyphausen-Aufsess, 2022; Konietzko et al., 2020). Experimentation is seen as part of a planned and consecutive process of strategy formation and works as a tool to pilot new CBMs before implementation and upscaling, explore new opportunities, develop partnerships, or generate data (Bocken et al., 2021). Similarly, literature on dynamic capabilities and CBMs shed some light on how a firm must experiment and adapt in response to environmental changes. But even here it is mostly the experimentation capabilities for validation purposes that are the focus (Bocken & Konietzko, 2022; Hofmann & zu Knyphausen-Aufsess, 2022; Sandberg & Hultberg, 2021). However, Dobson et al. (2018) propose, in a study of a social enterprise's process of scaling, that scaling and business model development are intertwined processes building on experimentation. In other words, emergent strategy processes happening in parallel and without deliberate goals.

Even though real-world strategies contain both planned and emergent elements, they are prone to verge to one side of the planned-emergent continuum (Mintzberg & Waters, 1985). The strategies that verge more towards the planned side are strategies that are formed and implemented with deliberate intention. A clear plan is first formulated and then collectively executed by the organisation with intended outcomes as a result. On the emergent side of the continuum, strategies are unintended or at least guided by vision rather than explicit plans. These strategies emerge out of practice in an undirected way and are often continuously modified (Neugebauer et al., 2016). Since they emerge out of practice it is difficult to separate the formulation phase from the implementation as this occurs simultaneously (Mintzberg & Waters, 1985).

The tendency to emphasise planning through rational decision-making and overlook the emergent strategies that develop in conjunction with short-term decision-making and personal experiences is common in research on sustainability strategy-making more broadly (Luederitz et al., 2021; Neugebauer et al., 2016). However, Neugebauer et al. (2016) propose that it is more likely that sustainability problems are addressed by emergent strategies since these problems are complex and uncertain (e.g., potential solutions are unknown, and experience from other problems is not transferable). Planned strategy-making requires problems that are clearly defined and would therefore be more prevalent in straightforward and controllable contexts (Mintzberg & Waters, 1985).

The problem of scaling CBM can be described as both complex and uncertain and it is therefore likely that emergent strategy-making is more common. Additionally, CBM initiatives often represent small organisations. This also speaks for the importance of looking beyond planned strategy-making and exploring emergent approaches. Luederitz et al. (2021) for example find that small firms that try to expand their sustainability activities integrate both emergent and planned approaches in a collective and distributed process. The collective ability of managers, customers and employees together influences strategic directions and corporate values.

This study aims to fill a gap in the literature by showing that experimentation in emergent strategy formation/implementation is important for the development and scalability of CBMs. That is, not only as a tool for validating claims before scaling (e.g. piloting) but it has a vital role in shaping strategies and thus the scaling process itself, as it unfolds. Since this perspective is largely overlooked in CBM literature, important knowledge for understanding how to grow CBMs from small-scale initiatives to larger organisations with the capacity for transformative systems change is missing.

To do this, a case from the fashion industry was chosen. The fashion industry represents a relevant industry where the development of CBMs has been put forward as a solution to social injustice and environmental pollution (European Environment Agency, 2019). Fashion brands and start-ups have during the last decades implemented and experimented with different CBM initiatives (Global Fashion Agenda, 2019). While many initiatives remain fragmented and small, secondhand has shown promise and currently represents a growing segment (BoF & McKinsey, 2021).

## Method

This study adopts an explorative and qualitative approach that builds on a single case study of a secondhand retail organisation's process of going to scale. In 20 years, the organisation has developed from operating a single store to an omnichannel chain of stores in three markets, with additional business offers and collaborations. This particular organisation was identified as representing a relevant case for how a CBM can scale through emergent strategies involving experimentation. Additionally, the development during 20 years as the organisation has grown to become one of few larger commercial secondhand retail organisations makes for a rich material to study strategy development over time.

Data were mainly collected through in-depth interviews and archival material from the organisation's homepage and social media platforms (see Table 1). The respondents were chosen since they had insights into when and why important decisions were made, and because they had been with the organisation long enough to have a historical perspective.

The material was collected and analysed in three phases. In the first phase, archival material and initial interviews were analysed to make a chronological list of important activities, events, and decisions relating to the scaling process. What to include in this listing was decided inductively from the material.

Following the definition of strategy "as a pattern in a stream of decisions" (Mintzberg & Waters, 1985, p. 257), the second phase aimed to find patterns representing overarching strategies and periods of change in the chronological list.

This was then synthesised in thick descriptions. Langley (1999) refers to this as temporal bracketing and explains it as a strategy for "structuring process analysis and sensemaking" (p. 703).

In the third phase, follow-up interviews were held to add depth and nuance to the analysis as well as help to clear up questions and validate assumptions. This was followed by a second analysis focusing on how the identified strategies evolved and their interdependencies.

## Findings and discussion

A phrase that the co-founder returns to in the interviews is "action begets action". From action new opportunities emerge, leading to new actions and new opportunities. New ideas and strategies are formed and implemented in an experimental approach where one idea feeds into another affecting the organisation's development and scale.

Two strategic paths, here presented in the form of narratives, illustrate how strategies emerge from ideas and actions rather than plans, tools and evaluations. The first narrative focus on the experimental approach that led to new geographical markets and the second focus on how experimenting with remanufacturing lead to collaborations, wholesale, and new customer segments. Common for these two examples is that they have been crucial to the organisation's development and overall growth process.

### *From one to three markets*

Opening new geographical markets are often preceded by calculation and deliberation. This was however not the case when the organisation opened their second market, three years after it took ownership of the first store in the UK. Around this time, the management had some vague ideas about expanding the business but had not decided on a direction. Instead, the second market came about almost by chance.

The organisation was approached by a former customer that was interested in replicating the concept in their new home country of Sweden. The co-founder liked the idea, went over to have a look, and after finding a suitable retail space they opened. This was an important event in the organisation's development but not something that was part of a planned strategy for expansion, instead, it emerged out of coincidences, actions, and different individuals' ideas and needs. They did not know if the concept would work in the new market but took action anyway and ended up establishing a new market with a new team. The Swedish market grew and during some periods operated more stores than the original UK market.

A few years later the organisation was presented with a similar opportunity, a former employee from the UK store decided to move back to Russia and wanted to open a store. They tried the same experimental approach and adapted the concept and set-up to the new context. However, this time they left the market soon after opening. The co-founder comments on this by saying that "The customer just wasn't there. I tried, I thought it was a fun idea, but it just didn't work".

While this experimental approach successfully established Sweden as a new but unexpected market, it failed to do the same in Russia. However, failure is part of an experimental approach. What is interesting to note is that in none of these two makes, stores opened in the form of pilots or tests. Instead, they opened as part of an experimental approach accepting that it might not work.

When they opened what is currently their third market, they instead followed a more planned approach. Finland was planned based on advice from both consultants and partners that could provide insights when it comes to both market and customers. This is in line with the idea that as a problem becomes less complex it is easier to form planed strategies (Neugebauer et al., 2016). At this time, they had accumulated experience, grown their network, and secondhand had increased in popular. The problem (i.e., knowing where and how to open their secondhand concept) had thus reduced in complexity.

### *From vintage to remanufacturing to wholesale and partnerships*

One of the challenges with scaling the sale of secondhand garments is that only a few garments are good enough to be sorted out and sold in a curated secondhand store. The organisation, therefore, started to experiment with remaking and redesigning used garments. It started with the simple question "can we cut the legs of jeans and make shorts?" and has grown to include one of the largest remanufacturing factories in the industry. A more planned approach to this could have been to develop the skills and styles before launching the concept. This was not their way, consequently, garments entered the stores with quality issues related to making and sizing. However, the organisation continued to learn and is now launching a new brand with higher quality remanufactured products.

From the remanufacturing, new actions and strategies have emerged. It is for example the starting point for what later evolved into the wholesale side of the business. The co-founder says that "wholesale was not part of an original business plan". It emerged when they were approached by a fashion brand that wanted to include some of the remanufactured products in their assortment. This initial action gave them the idea to pursue wholesale and reach out to more retailers, both big and small. This was a crucial change in the organisation's development that led to more collaborations, a wider network and more iterations down the line. Additionally, their collaborations with well-known brands have had the added advantage of reaching new customer segments as well as influencing the conversation of what fashion in a circular context is.

The experimental approach that the organisation use, where scaling strategies emerge out of practice and interaction with other actors, requires some financial muscle. There are no guarantees that experiments will succeed, and investments pay off, the organisation must therefore be prepared to gamble. However, actions can lead to unexpected opportunities and learnings which might be just what CBMs need to develop and upscale their operations. In a context where the problem is hard to define, such as scaling the many layers of a CBM, planning might not always be an effective approach (Neugebauer et al., 2016) but instead, lead to inaction.

## Conclusions

The findings show that an experimental approach where strategy emerges from action has played a vital role in the organisation's development. Strategies that have contributed to the organisation's development in the direction of becoming a leading secondhand retail brand have emerged from actions that lead to other actions in an experimental approach. By letting action lead them the organisation developed in directions that could not have been planned. It is unlikely that they would have developed the Swedish market or the wholesale business by analysing their organisation or their potential markets. It was strategies that emerged from allowing the organisation to follow ideas and shape new opportunities from action that made this happen. In contrast to many incumbent firms, the piloting stage is in this way sidestepped in favour of experimentation throughout the scaling process as the strategy is formed and implemented. Hand in hand with this is the networking capabilities that support experiments and form new strategic directions emerging from the connections and embedded experiences.

An emergent approach is not completely without planning. But what the narratives presented in this study show is that strategies emerging from experimental action shape the development and scaling of CBMs. As such they deserve more attention. A too narrow focus on planning might hamper organisational action and lead to missed opportunities.

This paper has some limitations, primarily from being based on a single organisation's development process and interview data that could suffer from recall biases (even though efforts were taken to limit this e.g., with triangulation). However, it should be seen as a starting point for a conversation about how we approach the problem of scaling CBMs. The findings suggest the need to look beyond tools and metrics when discussing CBM growth. Given that there are so many uncertainties when it comes to what a circular future would look like, emergent strategy-making is likely more common than what is reflected in the literature. Hence, future studies could follow the process more closely, preferably over an extended period to see how strategies are formed and implemented in real time instead of relying on historical documentation and recall.

# Restoring Sustainable Growth for Second-Hand Clothing Markets

**Abigail Irving-Munro**[(a)], **Alana James**[(b)]
a) Northumbria University, Newcastle upon Tyne, UK
b) Northumbria University, Newcastle upon Tyne, UK

**Keywords**: Regenerative consumption; Second-hand clothing; Localized economy; Doughnut economics.

**Abstract**: Consistent over consumption of low-quality clothing is having a detrimental impact on the environment, creating a significant global waste problem due to low product value and premature disposal. Consequently, this is having a negative effect on second-hand clothing markets as the quantity of donations increase, but the condition and quality of clothing decreases. The creation of a regenerative system in a localised economy would guide businesses to stay within planetary boundaries and help create even distribution of products throughout for the second-hand clothing economy. Furthermore, this shift in the traditional garment lifecycle would aid in prolonging the lifespan of garments through the creation of second-life opportunities and retainment of value for a sustained period of time.

The focus of the investigation was to propose a modified system design for the second-hand economy. Adopting a qualitative methodology, semi-structured, informal interviews with industry experts and consumers were conducted to gain insights into the multiple flows of clothing in the charity retail sector. This data will inform and direct the development of a regenerative distribution map, considering the flow of clothing in to, and out of, the charity retail sector.

As a result, problematic areas within the second-hand value chain were identified, with rationale for the congestion of clothing at specific points established. Insights into personal stakeholder agendas were also highlighted, approaching the identified challenge from multiple perspectives. Engagement with consumers detailed a pattern of consumption with the focus being on the purchase, use and disposal of products. Additionally, the cognitive process and rationalisation of these decisions were detailed, delving deeper into consumer attitudes and behaviours towards the clothing they own.

## Introduction

The Intergovernmental panel on Climate change (IPCC) has reported that global temperatures will exceed a 1.5 degree increase during this century, making it harder to limit warming to below 2 degree targets (IPCC, 2023). The fashion industry is one of largest polluting industries on the planet, producing 100 billion garments per year (Chan, 2022), and is constructed on a linear supply chain which is referred to as the *take-make-dispose* business model (MacArthur Foundation, 2021). Product lifecycles of garments are becoming shorter due to high levels of consumption, with the consumer desire for constant new styles causing ownership to often be short and premature disposal occurring. The average EU consumer throws away 11kg of clothing each year, with clothing consumption set to rise by 63% by 2030 (European Commission, 2022).

From a consumer perspective, there are many ways to get rid of unwanted clothing, the most popular is to donate or to pass clothing onto friends and family as a hand me down (Gregson et al., 2007), however resale using online platforms is a significantly growing market. Alternatively, consumers can dispose of clothing directly in the household bin, through charity shop donation, textile banks, door-to-door collections, corporate, school and community schemes, curbside collections, at local house hold waste and recycling centers (HWRCs), or through in-store take back schemes, where consumer donations are often rewarded through the provision of a discount voucher (WRAP UK, 2021).

Poor quality clothing has created an influx of clothing going to landfill sites, creating congested waste streams across the world. However, the globalized clothing supply chain has resulted in an uneven distribution of products, with the consumption levels of the lobal North, significantly effecting the global South (Niinimäki et al., 2020). This imbalance is largely due to the flow of clothing through second-hand economies, where garments are sold or donated to third part organizations or charity retailers. It is estimated that only 30% of used clothing given to these services will remain in the UK, while the remaining 70% will be exported overseas (Brooks, 2019). A geographical framework of countries deal with the UK's unwanted clothing with key destinations including West Africa, Poland and Pakistan (Smith, 2022). However, what is persistently overlooked is that 40% of clothing exported to those poorer destinations, such as Kantamanto Market in Ghana, goes directly to landfill opposed to remaining in circulation (Ricketts, 2019).

Used clothing is saturating global markets, however there is a growing phenomenon of new clothing populating second-hand overseas markets, which is thought to be caused by industry excess stock, with brands not being aware of the amount of new stock being discarded (Weber et al., 2023). New clothing is entering second-hand markets at an alarming rate, highlighting issues in the volume of clothing being produced for the first-hand economy. This flow of clothing is bypassing primary ownership and going directly to second-hand clothing economy, reducing the lifespan of the garment by an estimated 4-10 years (Klepp et al., 2020).

## Contextual Review

Considering the current climate crisis, it is paramount for society to create processes which will enable eco-systems and biodiversity to flourish, allowing both people and the planet to thrive together. A linear system of production and consumption is heavily reliant on the use of Earth's depleting natural materials, positioning the planet as a resource and contributing to rising global temperatures. To restore the equilibrium between people and the planet, industrial ecology theories have developed circular frameworks to eliminate waste by turning products back into valued commodities through recycling or biodegradability. This is done through the circulation of two different routes, the technical loop and the biological loop. A product in the technical loop which does not decompose is to be recycled, reused and resold, however there are many challenges within waste management strategies and recycling capabilities. The biological loop creates products which can return to their natural state through decomposition, retaining value through the enrichment of terrestrial environments. These principals are reflected by multiple authors with many being based on the Cradle-to-Cradle framework, which initiated a circular approach where humans and other living species are considered within the wider context (McDonough, 2002). Another approach to implementing circular values was pioneered by Janine Benyus (2009), with *biomimicry* being the study of nature's models to inspire and inform designs and processes to solve human problems. A further theory which uses seven ways of thinking in support of the planet's natural systems is Doughnut Economics by Kate Raworth (2017), which utilizes two circular boundaries to create the doughnut shape. The inner circle of the doughnut is made up of 12 elements which is the social foundation, and the outer circle of the doughnut is made up of 9 elements which are the planetary boundaries. The economy sits in the middle of these two boundaries with the aim being to keep within the planetary boundaries zones by creating an ecological ceiling. The system encourages businesses to take into consideration all the ecological elements that instigate a healthy planet, with this method being applicable throughout the entirety of their business model. By using Raworth's seven ways of thinking, companies can sustain good business with conscious solutions instead of using the infinite growth model and being a part of a degenerate linear process. It is highlighted that one of the seven ways of thinking like an economist is *design to distribution* (Raworth, 2017), focusing on a network which works locally in the area instead of having a long logistical network which spans across the globe. The process creates a systems thinking approach (British Fashion Council, 2022), and alters the supply chain to encourage products to be sourced and manufactured in a localized economy.

As the fashion industry shifts from a linear economy to a circular economy, it is evident that the second-hand economy will need to become a regenerative system. Within the fashion industry, responsible practice encompasses not only decisions made within the design of a product but also by looking at the long logistical supply chain, considering how a brand can transition to support people and their environment (Franco Henao, 2022). Prolonging the life span of a garments is an effective way to relieve landfill sites in the global south and keep distribution of second-hand clothing flowing within a localized market.

## Methodological Approach

The aim of the study was to investigate how used clothing can be redistributed, re-used and re-entered in a localized economy. This approach will prevent clothing being transported across the globe through a long logistical network to end up in landfill sites geographically located across the world. The creation of a value chain for used clothing would prolong the life span of garments, and in the process adopt a regenerative approach in the second-hand economy. The study used critical thinking to support the methodological approach to then embark on a systems design framework and follow an iterative process throughout the study.

This qualitative research adopts an interpretivism and phenomenological research paradigm, which has been created to articulate the best possible way to restore sustainable growth for second-hand clothing markets. This ongoing investigation will contribute to a new field of knowledge and highlight areas in academic research previously unexplored. Firstly, to fully comprehend at what stages in the value chain clothing filters out of the system and becomes degenerate, three experts were called upon to participate in semi-structured interviews. Once all interviews had been conducted, recorded, and transcribed, data was thematically grouped individually for each data set, and then cross analyzed across all three of the interviews. The results from this process informed phase 2 of the fieldwork, where consumer perspectives were incorporated into the study. Understanding of how clothing will be purchased, worn, and disposed of was critical to the research, to fully comprehend the pace of consumption and the rationale for consumer behaviors. After further analysis, it became clear that contemporary consumer culture is impacting second-hand clothing purchasing behavior, and thus contributes to the amount of clothing going to landfill.

*Phase 1*

Gaining insight from industry stakeholders was crucial to the research to provide knowledge from a range of different perspectives. After collecting a wealth of secondary data and developing a supply chain map of the second-hand economy, the findings indicated there were three key areas which needed to be explored further. The three participants were a policy maker for the Charity Retail Association, the CEO of a Ghanian upcycling company and a charity retail store manager. For each interview a set of questions were developed to reflect their area of expertise, using open questions to give the participants a chance to further discuss in detail different areas which were of interest. Before conducting the interview, empathy maps for each participant were developed. This was a way to empathize with the participant and capture true belief systems leading the researcher to a rich data set.

*Phase 2*

It was evident from the data generated in phase 1, that the gen Z population were the most active on social media platforms which buy and trade in second-hand clothing and were therefore selected to be the participant demographic for this phase of the consumer study. This directed the study to explore further into contemporary consumer culture and the different patterns in consumption behavior, highlighting the critical decisions regarding the lifespan of clothing. After gathering the participant's thoughts and feelings towards buying second-hand, the participants were asked about their own clothing to investigate three critical areas which signify the garment lifecycle (purchase, use and disposal).

## Findings

Key insights gained from the stakeholder interviews aided in the understanding of the flow of garments throughout the second-hand market, progressing from the first-hand economy, through donation or collection and into the second ownership phase of the product lifecycle. Engagement with the Charity Retail Association highlighted the importance of governance and policy surrounding the second-hand sector, with new clothing being received positively for the potential financial gain for the charitable organization. Insights from a global South perspective were also gleamed from the interview process, with critical barriers and challenges being positioned around the type and quality of clothing received from developed markets from countries such as the UK. Furthermore, on the ground information was provided from a charity retail perspective, with sorting, provision and once again quality framing critical challenges in the sector.

Key findings from the consumer study began to provide insights into the consumer to product relationship and the value that consumers place of their clothing. Considering this from a product use point of view, it was found that garments which were frequently worn were chosen due to their multifunctionality, meaning they could be worn for many occasions, and tended to wash and age well. This highlighted the key factors which were identified by consumers to be important in their clothing choices including quality and ability to adapt to the body when being worn. Clothing which consumers wanted to get rid of, seemed to have been bought without too much consideration, was beginning to fall apart or was too hard to keep clean. These qualities were cited frequently when consumers did not value the item of clothing and would willfully donate or get rid of the item.

The key findings from phase 1 and phase 2 were then considered using Raworth's seven ways of thinking, with core insights being visualized to show the interrelationships between ecological and economic constructs. Laricks's (1988) *agricultural regenerative system* diagram was utilized to form the basis of this visualization, with details being adapted and recontextualized to reflect a potential future direction for a regenerative fashion system.

Four elements were mapped to indicate critical considerations in the development of a regenerative system: *ecological regeneration* under pins the ecological needs for the planet fragile ecosystem to be restored; *regenerative social development* reflects a lack of transparency in the supply chain, with the need to develop a diverse and a healthy work force; *ecological breakdown* reflects the destruction of earths living systems through the expansion of landfill sites inditing wasteful products, toxification through chemicals and the contamination of waterways and the loss of fertile soil through over production; *social breakdown* indicates a work force in persistent poverty or unemployment, through the exploitation of poorer communities and developing friction through lack of financial support, health and welfare.

This framework sits on a sustainable axis with these four crucial elements positioned in relation to one another, demonstrating an ecological system reliance on the consideration or people, planet and profit. The model indicates how businesses can shift from a degenerative to a regenerative system, with each step implemented in a methodical order to develop a responsible business model where planet and people can thrive together.

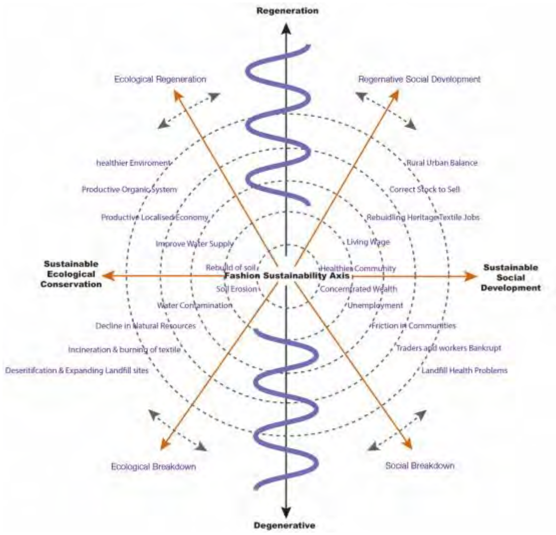

**Figure 1. Fashion's Regenerative System (based on Larick's (1988) Agricultural Regenerative System)**

The diagram considers four critical elements; regenerative social development; ecological regeneration; ecological breakdown; social breakdown. Each ring cascades through these different areas and by adopting Raworth's (2017) ways of thinking, figure 1 demonstrates that for fashion to move from a degenerative to a regenerative system, the full breadth of social and ecological factors need to be encompassed through positive and strategic action. The used clothing sector harvests many of the systemic problems which are highlighted in the lower parts of the circle, therefore each issue needs to be carefully considered to instigate supply chain management to work towards meaningful change and establish a new way of working. Holistically mapping the second-hand clothing sector could help companies engage with these issues, considering the imbalance between the global north and south and developing a framework which steers businesses away from a linear degenerative model.

## Conclusions

The two phases of primary data collection have demonstrated a rigorous investigation, where qualitative research methods have been utilized to guide the research through the different phases. A diagram has been hypothesized which could help future businesses develop a visual map, which can deploy a regenerative system in the second-hand clothing economy. A gap in existing knowledge has been identified, with relatively little currently know regarding the presence of new clothing within the second-hand economy. It is to be acknowledged that large amounts of clothing already within circulation cannot be recycled due to fiber content and therefore extended or secondary lives rely on the product entering the second-hand markets. The action required to help shift practices towards regeneration include the empowerment of stakeholders to instigate positive action, orchestrating trading practices which prevents colonial waste issues for countries in the global south. Furthermore, diverting clothing away from landfill and creating sorting systems that are built upon networks which have a robust infrastructure is paramount to start moving fashion away from degenerative practices, towards a prosperous regenerative system for the future.

# The Influence of a Hypothetical Eco-Score on Purchasing Mobile Phones: Conceptual Considerations and Preliminary Findings

**Kathleen Jacobs**[a], **Jens Bergener**[b], **Maike Gossen**[b]
a) Wuppertal Institute for Climate, Environment and Energy, Wuppertal, Germany
b) Technical University Berlin, Berlin, Germany

**Keywords**: Adaptive choice-based conjoint analysis; cluster analysis; eco-score; consumer segment, sustainability label.

**Abstract**: Integrated sustainability labels, such as a multi-level eco-score label, are increasingly recognized as effective in promoting sustainable consumption. This study investigates consumer preferences for a hypothetical eco-score when purchasing mobile phones, alongside preferences for conventional and other sustainable mobile phone attributes including a product longevity tag. In addition, the study identifies and characterizes consumer segments based on preferences for a total of eleven mobile phone attributes, participants' consciousness for sustainable consumption, and social demographics. Using adaptive choice-based conjoint analysis and cluster analysis, we find that an eco-score has an approximately linear, positive effect on purchase behavior. Among the four identified consumer segments, *brand and eco shoppers* and *new and equipment shoppers* have comparatively strong preferences for higher eco-score levels – signaling untapped market potential for sustainable mobile phones. Business practitioners are advised, for example, to improve their environmental product performance, use segment-specific marketing strategies and implement multi-tier distribution systems. Policy makers are encouraged to test the implementation of an eco-score label in the consumer electronics industry.

## Introduction

By reducing information asymmetries between consumers and producers, sustainability labels are discussed as a promising means to help consumers make sustainable purchase decisions (e.g. Acharya 2020, Bratt et al. 2011). At the same time, literature points to the limitations of current sustainability labelling schemes. For example, Fuso Nerine et al. (2019) argue that they only focus on single aspects of sustainability. As a result, different labels are often used simultaneously, contributing to confusion, information overload, and misunderstanding among consumers (e.g. Horne 2009, Monier-Dilhan 2018). A systematic literature review by Torma and Thøgersen (2021, p. 1) summarizes that "the current sustainability labelling landscape is up against the challenge of too much, too complex, too similar, and too ambiguous information". Instead, they propose integrated sustainability labels that are multi-dimensional and preferably multi-level, i.e. they go beyond categorical (yes or no) compliance with a minimum standard, which makes it easier for consumers to understand how well a product performs in terms of sustainability (Torma and Thøgersen 2021).

In the context of research on integrated sustainability labelling, a (hypothetical) eco-score has recently been discussed and investigated in studies on sustainable food consumption (e.g. De Bauw et al. 2022a, De Bauw et al. 2022b, Marette 2022). The eco-score aims to integrate several dimensions of a product's environmental sustainability. Typically, the sustainability performance of a product is rated on a letter-based traffic light scale ranging from 'A' (dark green) to 'B' (green), 'C' (yellow), 'D' (orange) and 'E' (red). While the eco-score is only used in practice in some European countries such as France for food, a debate has already started on the introduction of a European eco-score for different product categories (cf. Pistorios and Foote 2021).

Given the strong negative sustainability impact (e.g. Cordella et al. 2020, Ercan et al. 2016), a transformation of the consumer electronics industry, and the mobile phone sector in particular, is inevitable to achieve sustainable development (Griese et al. 2005). Previous sustainable consumption research on electrical appliances has focused on testing only single, rather specific sustainability information, mainly related to a product's energy efficiency and circular economy by using experimental research designs (e.g. Jacobs and Hörisch 2022, Heinzle and Wüstenhagen 2012, Hunka et al. 2021). Overall, these studies show that multi-level sustainability information positively influences purchase decisions for electrical appliances. However, the sustainability information tested only focuses on very specific aspects of the product's environmental sustainability performance – in contrast to a more holistic eco-score.

Furthermore, knowledge about the existence of consumer segments and the role of certain consumer characteristics in the context of sustainable mobile phone purchases is limited (e.g. Boyer et al. 2021a, Wilhelm 2012), although this would be of great benefit for manufacturers and retailers to target potential sustainable mobile phone customers. To address these research gaps, we formulate the research questions as follows:

1. What are consumers' preferences for a hypothetical eco-score when buying mobile phones?
2. Can consumer segments with different preference structures be identified when buying (sustainable) mobile phones? If so, how can they be characterized in terms of their psychographic and sociodemographic profiles?

## Conceptual considerations

To address the research questions, Lancaster's (1966) consumer theory is used as a theoretical framework. Based on these theoretical assumptions, the influence of individual product attributes can be identified, studied and compared with others in purchase decision contexts where many different product attributes simultaneously influence behavior.

In research on sustainable food consumption, the debate on the relevance and influence of a multi-level (hypothetical) eco-score integrating several ecological product criteria has recently gained momentum (e.g. De Bauw et al. 2022a, De Bauw et al. 2022b, Marette 2022). Despite the great potential for strengthening sustainable consumption in the mobile phone market, there is a lack of research on consumer preferences for a hypothetical eco-score of mobile phones. We argue that findings on the positive impact of an eco-score on purchase decisions in the food context can be transferred to the mobile phone context. This is supported by the limited number of studies that have investigated consumer preferences for (hypothetical) information about sustainable attributes of mobile phones, indicating that such sustainability information generally positively influences purchasing behavior (e.g. Boyer et al. 2021b, Hunka et al. 2021, Mugge et al. 2017, Van den Berge et al. 2023). In addition, we assume that consumers do not associate disadvantages with a strong overall environmental performance of products. We thus assume a linear effect of the eco-score. Therefore, we formulate hypotheses as follows:

**H1:** Higher levels of a hypothetical eco-score have a positive influence on the purchase of mobile phones.
**H2:** The positive influence that a higher hypothetical eco-score exerts on the purchase of mobile phones increases approximately linearly with an improvement in the hypothetical eco-score.

There are only a few segmentation studies in the mobile phone context that consider sustainable product attributes (Boyer et al. 2021a, Mugge et al. 2017, Wallner et al. 2022). Moreover, none of the segmentation studies consider preferences for the overall environmental impact of a mobile phone, expressed for example by an eco-score. Based on these previous findings, we want to confirm that segmentation into at least two consumer segments is possible, and we also hypothesize that the eco-score plays a particular role in this:

**H3:** Consumer segments with different preference structures regarding the purchase of mobile phones, which also have sustainable attributes, can be identified.
**H4:** Consumers' preference for a hypothetical eco-score contributes to the separation of consumer segments.

Standard marketing management and consumer segmentation literature (e.g. Kotler and Keller 2021, Wedel and Kamakura 2000) and previous research on characterizing sustainable consumers (e.g. Diamantopoulos et al. 2003, Krause and Battenfeld 2019) has highlighted the need to examine not only sociodemographic but also behavioral and/ or psychographic consumer characteristics. Several empirical studies have shown that consumers' consciousness for sustainable consumption (CSC) – considering environmental, social, and economic aspects of consumption – significantly affects various types of sustainable consumption behaviors (e.g. Balderjahn et al. 2013, Balderjahn and Hüttel 2019). Therefore, we hypothesize that CSC and the sociodemographic factors are useful to characterize consumer segments in the context of sustainable mobile phones:

**H5:** Different types of consumers' CSC serve as differentiators between consumer segments.
**H6:** Sociodemographic characteristics serve as differentiators between consumer segments.

## Methods

This quantitative-empirical study applies adaptive choice-based conjoint analysis to test the hypotheses. Through an online survey completed by a nearly population-representative sample in Germany (n = 534), consumer preferences are tested for eleven attributes of mobile phones, including a hypothetical eco-score, separate information tags on product longevity, fair production and trade and $CO_2$ compensation, as well as a number of conventional product attributes such as price, brand and equipment version (see Table 1).

| Attribute | Attribute level | Visual representation in experiment |
|---|---|---|
| Price | €99 | |
| | €199 | |

**Table 1. Attributes and attribute levels of mobile phones in the conjoint analysis.**

In addition, a cluster analysis is conducted to identify potential consumer segments, which are then described based on social demographics and respondents' CSC (cf. Ziesemer et al. 2016).

## Preliminary findings

Our preliminary results show that higher levels of a multi-level eco-score have an approximately linear, positive effect on the purchase of mobile phones. Furthermore, the eco-score proves to be more important to consumers than all other sustainable product attributes. For example, the eco-score is more important than sustainability tags that are reduced to a single attribute level such as 'durable' of the product longevity tag. Four consumer segments can be distinguished: 'price shopper', 'brand and eco shopper', 'new and equipment shopper' and 'average shopper'. Consumers' preference for an eco-score, almost all types of CSC as well as age and educational level contribute substantially to the differentiation of the segments.

The contributions of our study are manifold. For example, it contributes to the emerging academic discourse on integrated, multi-level sustainability labels and confirms initial findings on an eco-sore in the food sector. The study provides first empirical evidence on the effectiveness of a hypothetical eco-score in promoting mobile phone purchases and is the first segmentation study in the context of sustainable mobile phones that investigates consumer preferences for a product's overall environmental impact. By identifying and characterizing two sustainability-sensitive segments (*brand and eco shoppers* and *new and equipment shoppers*), the study identifies untapped market potential for sustainable mobile phones in Germany. For example, business practitioners are advised to improve the environmental performance of their mobile phones, use segment-specific marketing strategies and implement multi-tier distribution systems. Policy makers are encouraged to test the implementation of an eco-score label in consumer electronics.

Previous research on food suggests that the impact of an eco-score may be limited if it is provided together with the Nutri-Score (De Bauw et al. 2021). Future research should therefore investigate whether adding an eco-score label to existing or at least previously tested consumer electronics labels, such as the EU energy efficiency label, a repairability score, or a product lifetime label, may increase information overload and lead to ambivalent consumption choices.

# Coping with the challenges of battery logistics: Analysis and application of supply chain decision indicators for sustainable and circular logistics for vehicle batteries

**Jan-Philipp Jarmer[(a)], Charlotte Joachimsthaler[(a)]**
a) Fraunhofer Institute for Material flow and Logistics (IML), Dortmund, Germany

**Keywords**: Battery logistics, Sustainable supply chain management, Key performance indicators, Circular economy, Lithium-ion-batteries.

**Abstract**: Vehicle batteries as a key technology are experiencing a strong upswing in production and take-back due to the growth of electromobility. Both the urgency and the requirements for efficient logistics networks are growing. In addition, there is the dependency on other countries because Europe is poor in certain raw materials. Logistics processes extend across borders, since battery electric vehicles are used widespread in the world. Knowledge transfer takes place only to a limited extent due to competitive pressure, but with a simultaneous demand for transparency. Lack of capacities and inefficiencies in supply chains and reverse logistics networks weaken the benefits of electric vehicles. In order to meet the challenges mentioned above, KPIs were collected in this paper based on a literature review and discussions with experts from the industry, which are recommended to evaluate supply chains in the context of sustainability and circularity.

## Introduction

As a result of the energy transition, the demand for cars with electric drives is expected to increase sharply. According to forecasts, by 2030 there will be almost 34 million pure electric cars and 13.8 million plug-in hybrids on Europe's roads (Ceresana 2021).

In order to be able to meet this high demand in the future, innovative logistical concepts are required in which, in addition to safety-related and regulatory aspects, the dimension of sustainability and related after-sales questions should also be taken into account. After the so-called "first life" of the batteries, various options for subsequent use or recycling can follow, which include for example remanufacturing, “second life” applications, e.g. stationary energy storage, or recycling processes for batteries (Figure 1).

These treatment variants find different degrees of coverage in the EU states, but all have in common that logistics systems play an important key role in efficiently closing cycles and thus enabling circular and sustainable supply chains (Fennemann et al. 2018).

The targets proposed by the EU Commission for carbon footprint statements, collection rates, recycling efficiencies and minimum recyclate content for new lithium-ion batteries will lead to extensive investments in new recycling capacities and technologies (European Commission 2023a). For a holistic Circular Economy, however, value preservation strategies and technologies for other possible after-sales paths must also be considered and industrialized. So far, there has been a lack of a profound data basis with effective Key Performance Indicators (KPIs) for both improving the preservation of value of batteries and the associated logistics processes.

In the area of tension between a sustainable Circular Economy and safety-relevant measures as well as official regulations, this paper deals with the challenges of battery logistics, and describes and analyses the inherent logistics processes as an essential part of a Circular Economy. In this context the central research question is: Which additional data and KPIs need to be considered to improve the logistics processes in pre-sales and after-sales activities, which in turn could have a positive effect on the sustainability of batteries and logistics industry?

## Context

A holistic view of battery logistics is of fundamental importance (Figure 1). It starts with the procurement logistics, which includes the purchase of the necessary raw materials and components. After the procurement logistics, the multi-stage production begins. The production logistics range from material preparation and component manufacture, e.g. cells and modules, to assembly of the battery and covers both internal and external storage and transport processes. Installation in the vehicle and distribution are part of the battery's distribution logistics. Even before the usage phase, waste such as production residues, packaging or rejects can accumulate at all levels of the material flow and needs to be treated. Currently, the focus is on the ramp-up of series production (pre-sales), which includes the optimization of the manufacturing processes and the associated logistical processes. At the same time, an increasing number of faulty and end-of-life batteries can be expected in the after-sales market, which can be routed via various reuse or recycling paths. After use in cars, batteries reach the end-of-first-life. Now the Circular Economy for batteries comes into play, starting with collection and disassembly activities. Battery logistics should support this Circular Economy and preserve the batteries and components for as long as possible. To this end, it aims at the following activities:

- Rework: post-processing of production errors
- Repair: measures in workshops
- Reuse: original use of the batteries after inspection
- Refurbishment/Remanufacturing: overhaul or rebuilding of the batteries
- Repurpose (2nd-Life): secondary usage options, e.g. stationary energy storage
- Recycling: destruction of the batteries to recover materials

These options for subsequent use are often referred to as R-strategies (Potting et al. 2017). It is important that possible gains in efficiency are not used up elsewhere (rebound effects). Therefore, the sustainable closing of material cycles requires multi-stakeholder cooperation in complex value chains.

## Methods

For describing the status quo of battery logistics, focusing lithium-ion batteries for electric vehicles, existing literature and data were examined. The literature review was conducted with the aim of answering the following key questions:

- What criteria are used to define a supply chain as sustainable?
- What are the specific requirements associated with battery logistics?
- What are appropriate data sources for traction battery supply chain assessment?

In this context, four review papers with publication dates between 2021 and 2022 were evaluated using the snowball principle (Joshi 2022; Arshad et al. 2022; Li et al. 2022; Slattery et al. 2021). This provided an insight into a cross-section of over 200 studies with publication dates between 2010 and 2021.

Relevant stakeholders with different perspectives and interests in the supply chain in the area of pre-sales and after-sales of traction batteries are those mentioned below:

- Suppliers of purchased parts/sub-components
- Cell, module and battery manufacturers
- OEM
- Market/user
- (specialized) Disposal and recycling companies
- Logistics service providers (storage, handling, transport)
- Providers in the field of alternative after-sales options
- Regulatory institutions

By collaboration with partners from the nationally funded project "Innovation Lab for Battery Logistics in E-Mobility", interviews could be conducted with the following focus groups to capture different perspectives:

- Provider of alternative after-use options (2nd-Life)
- Dismantler and recycler
- Logistics service provider

Current challenges and inefficiencies were discussed. Supporting KPIs were used to describe potential set screws. On this basis practical suggestions, including sample processes for an improved information logistics, for all actors along the batterie value chain were derived to cope with the upcoming changes in legislation.

## Challenges

An overview of selected challenges in the battery life cycle will be given. Starting with procurement logistics, many materials relevant to battery production - not just lithium, cobalt and nickel - are associated with a supply risk. In this context, the European Commission has published a list of so-called critical raw materials every three years since 2011 in order to "*reduce dependencies in all dimensions – by sourcing of primary raw materials from the EU and third countries, increasing secondary raw materials supply through resource efficiency and circularity, and finding alternatives to scarce raw materials*". Critical raw materials are taken into account to be those that have high economic importance for the EU and a high supply risk (European Commission 2023b). Thus, a raw material is considered critical if the limited availability of the material cannot cover the rapidly increasing demand from industry worldwide. The reasons for this are many technologies that need the material, but also political and geographical circumstances or conflicts.

In the future, an increasing demand for raw materials for renewables and electromobility is to be expected, compared to 2018 it is assumed that up to 18 times more lithium and five times more cobalt in 2030, and 60 times more lithium and 15 times more cobalt will be needed in 2050 (European Commission 2020). However, these essential materials are mainly concentrated outside Europe, in countries such as Australia, Chile, China and the Democratic Republic of the Congo. Logistics is necessary for early warning systems and information management. Furthermore, measures that reduce the use of primary resources - from extending the lifespan, to recovering materials - can also be supported. Concern about the availability of raw materials is one thing. The other dimension is that the extraction of raw materials also requires energy and will therefore be a not insignificant factor for greenhouse gas emissions and environmental impacts in the coming years. Electromobility and the Circular Economy can certainly have opposing tendencies and must be properly coordinated (Schäfer 2021).

For the storage phase of batteries and their components, e.g. cells and modules, no overarching standardization of the requirements exists. The biggest challenge when storing batteries is getting approval from the insurance company and approval from the local authorities. Missing empirical values or comprehensible guidelines that support the authorities and the fire brigade in approving fire protection concepts lead to very heterogeneous decisions on the safety and fire protection concepts for storing batteries. These uncertainties in the context of qualification processes for logistics real estate for storage of batteries can lead to a backlog of investments, a lack of capacity and ultimately to inefficient decisions (Plotnikov et al. 2023).

The transport of batteries by road, rail, sea and air is bound by transport laws. Batteries for electric vehicles are classified as dangerous goods. For more safety in transport, preventive and early warning concepts for logistics service providers, through temperature monitoring and condition monitoring, are recommended (AGCS 2022). The transport of critical batteries, which tend to react dangerously, is particularly challenging. Special containers and special transport requirements come into play. Often these containers must not be stacked and, as a result, transports are not fully utilized.

For the return of batteries different logistics relationships can be distinguished. While factories can be connected to disassembly plants with shuttle services, batteries that accumulate in distributed workshops could be initially consolidated in order to address the requirements of the notification and consent procedure efficiently.

As soon as the batteries are removed from the vehicles in the workshops, the question of routing arises. The description of a digital decision-making process chain is needed in order to initiate subsequent processes in a targeted manner. Because taking back batteries does not just mean that modules and cells are treated further. Numerous other take-back activities are induced by other material fractions contained in batteries.

Safety must always be guaranteed, but it must also be ensured that collection, disassembly and options for subsequent treatment contribute to sustainable development and do not work against it from a certain point. This requires technical and logistical innovations and standards to be able to process the returning battery quantities in the future. Therefore, exemplary KPIs are proposed, which should facilitate the monitoring of the battery life cycle from a logistical perspective and strategic decision-making.

## Results

To address the challenges along the supply chain of traction batteries, it is useful to capture and review KPIs in view of the respective supply chain in order to derive improvement measures. Based on the literature analysis, the review of regulations and discussions with project partners, the KPIs listed in Table 1 and located in the Big Picture could be derived.

With the assumption that those KPIs that address the performance of the battery or its performance during the use phase (e.g. State of Health) are not representative of the quality of the logistical process system within the supply chain, these were not initially listed.

Most existing network models focus on profitability and costs (Joshi 2022). However, the KPIs cannot always be clearly assigned to a sustainability dimension (ecological, economic), since interconnections exist. As part of the energy transition lower energy consumption is often ecologically motivated and saves energy costs (classified as "overarchingly motivated") as well.

Concerning “ecologically motivated” KPIs one could assign the recycled material content. The recycled content is determined by the material composition in the manufacture of the batteries and the associated procurement, but the quality of the recyclate and the possibility of returning it in a closed cycle depends heavily on the quality and efficiency of the recycling process of the old battery.

For some KPIs (e.g. production costs), mature approaches to calculation already exist, for others there is no widely implemented solution. In view of the challenges outlined, reverse logistics and R- strategies with associated KPIs are specifically addressed.

| No | KPIs | Mot. |
|---|---|---|
| 1 | Recycled material content | ecol |
| 2 | Supply risk | over |
| 3 | Economic importance | econ |
| 4 | Scrap rate (efficiency) | econ |
| 5 | Procurement costs | econ |
| 6 | Production costs | econ |
| 7 | Share of alternative drive technologies in transport logistics | ecol |
| 8 | Waste from transport packaging | ecol |
| 9 | Operating and storage costs | econ |
| 10 | Transport costs | econ |
| 11 | Costs for packaging or load carriers | econ |
| 12 | Transport utilization (weight and/or volume) | over |
| 13 | Failure rate (logistics) | over |
| 14 | Recycling rate | ecol |
| 15 | Recycling efficiency | ecol |
| 16 | Rework rate | ecol |
| 17 | Repair rate | ecol |
| 18 | Repurpose rate | ecol |
| 19 | Refurbishment/Remanufacturing rate | ecol |
| 20 | Reuse rate | ecol |
| 21 | Collection rate | ecol |
| 22 | Greenhouse gas emissions company (direct) | ecol |
| 23 | Greenhouse gas emissions supply chain (indirect) | ecol |
| 24 | Greenhouse gas emissions product | ecol |
| 25 | Energy consumption company (direct) | over |
| 26 | Energy consumption supply chain (indirect) | over |
| 27 | Energy consumption product | over |
| 28 | Regional value creation | over |
| 29 | Technology status | over |

**Table 1. Key Performance Indicators (ecologically motivated, economically motivated, overarchingly motivated).**

There are many and diverse circularity indicators for decision-making that have different advantages and disadvantages (Oliveira et al. 2021; Hatzfeld et al. 2022; Figge et al. 2018). For this reason, only individual points that need to be taken into account for the KPIs listed here will be discussed below.

Basically, the question of the reference value arises for every indicator. This question is important because each reference value has a different meaning. For example, in the comparative analysis of two supply chain scenarios, it must be specified which reference value is to be used to evaluate e.g. the failure rate. In this context, it must be determined whether failures in logistics processes are measured in a defined period of time, which logistics processes are relevant for this, whether a number is to be specified or whether these are to be calculated, for example, by transport services (e.g., tkm or km). The situation is similar for quotas or rates. The proposal for the Battery Directive includes some known rates, such as the recycling rate. Alternative R-strategies that extend the life of the battery and components, such as repair and remanufacturing, are addressed, but associated minimum values for rates are not included. Independently, one can speak of input-oriented and output-oriented rates, the latter evaluating the efficiency of the process, an example:

- Input-oriented repair rate (analogous to recycling rate): Percentage of waste batteries that can be repaired; calculated by the ratio of the mass of waste batteries transported for repair and maintenance to the total mass of waste batteries.

- Output-oriented repair rate (repair efficiency, analogous to recycling efficiency): Percentage of waste batteries repaired; calculated by the ratio of the number of batteries actually repaired and functional again for vehicle use to the total number of waste batteries.

The idea of efficiency becomes particularly relevant when current trends towards cell-to-chassis constructions as well as potting or bonding of the cells are implemented and repair and disassembly of individual components can no longer be realized technically or only with increased scrap rate.

In addition, the unit with which one calculates is also relevant. For example, a conversion of the product, here a battery from the use phase into several modules for a 2nd-life application as stationary storage by disassembly, must also be taken into account. Thus, an input-oriented repurpose rate may well be calculated with the unit of pieces of batteries. However, this does not make sense for an output-oriented repurpose rate, since the product output is different (in the disassembly modules and in the actual repurposing stationary energy storage). In this context, a material flow-oriented unit, e.g. kilograms or tons, is recommended.

To be able to evaluate the KPIs, various data sources that belong to the market or are company-specific must be utilised. Current developments of a battery passport, a digital twin and other measures to increase the transparency of different data can be useful in this context. Tracking the data that the battery management system collects anyway could also be helpful. However, right now accessing and retracing this data as a basis for evaluating the supply chain is only possible to a limited extent (in sufficient quality and completeness) and is associated with a high expenditure of time and money.

## Conclusions

In the future, batteries must be handled safely, promptly, and above all with a minimal environmental impact, between source and sink. The aim of this work is to put together the framework conditions for a rapidly growing need for an effective and sustainable supply chain management in such a way that the requirements of all actors involved can be quantified with the help of KPIs. While the EU Commission suggests precise recycling efficiencies and minimum recyclate content for batteries, it is recommended to also monitor other value preservation strategies. Moreover, the planned battery passport should provide more transparency to reduce the loss of information along the value chain, but the question of how logistical challenges and efficient networks can be planned and monitored remains. For future battery quantities, concepts for regional value chains are to be implemented to improve the Circular Economy approach for batteries, to guarantee raw material security and availability and to minimize transport efforts. Further research will focus on adequate data gathering in the value chains and developing a comprehensive set of tools and further indicators for deeper analysis and optimization to verify its practicability for a battery Circular Economy.

# Circular Economy in the construction industry: Analysis of the usage of RC-concrete in precast production

**Pauline Jegen[a], Martin Faulstich[a]**
a) Chair of Resource and Energy Systems, TU Dortmund, Dortmund, Germany

**Keywords**: Construction industry; Circular economy; Recycled concrete; Recycled aggregates; Precast.

**Abstract**: The construction industry and demolition of buildings in Germany generate a significant amount of mineral construction and demolition waste (CDW), which can be recycled and used as a substitute for natural aggregate in producing new building materials. Using recycled aggregates in concrete production is beneficial for two reasons: the need for new building materials and the usage of the significant amount of CDW generated. When distances between demolition, recycling, and construction sites are short, using recycled materials not only conserves natural resources but also reduces $CO_2$ emissions from transport. The presented circular economy approach, which involves reusing building products at the end of their primary use, can further extend the lifetime of materials and therefore remain the grey energy used for concrete production. To determine which precast products can be produced with recycled concrete (RC-concrete), an evaluation matrix that considers relevant technical and legal rules is used. The study uses a bottom-up approach to analyze material flows and assess the available amount of primary material (CDW) and demand for precast elements in Germany. The research demonstrates that most precast products used for standard houses can be built with RC-concrete, and the amount of recycled aggregates needed is covered by German CDW. This study contributes to the development of holistic circular economy solutions in the construction industry that save primary resources and reduce $CO_2$ emissions by increasing product lifetimes.

## Introduction

The construction industry is one of the largest contributors to global greenhouse gas emissions and generates significant waste, particularly in the form of construction and demolition waste (CDW). With urbanization and population growth, construction activities are only set to increase, leading to an increase in demand for raw materials. The concept of circular economy (CE) aims to minimize resource consumption, waste production, and resulting emissions by optimizing material cycles through efficient resource use, extended service lives, and closed-loop recycling. The reuse and recycling of CDW is one CE approach for the construction sector.

## CE in the construction industry

### *Recyling of CDW in Germany*

220,6 Mio. t of mineral construction waste was generated in Germany for 2020 (Bundesverband Baustoffe – Steine und Erden e. V., 2023). 60,0 Mio. t are classified as construction rubble out of which 78,8% are recycled. (Bundesverband Baustoffe – Steine und Erden e. V., 2023). German waste statistics do not classify the construction rubble further, but according to Kurkowski and Müller construction rubble consists of 47 mass % masonry rubble and 53 mass % concrete rubble (Kurkowski & Müller, 2017). This assumption leads to 28,2 Mio. t masonry rubble and 31,6 Mio. t construction rubble. The largest share is used in road and earth construction. In addition, the use of RC building materials for the production of recycled concrete, so-called RC-concrete, represents a field of application (Müller & Martins, 2022). However, RC-concrete accounts for a small proportion of the concrete produced in Germany only.

### *RC-Concrete and Its Application*

Concrete is one of the most commonly used composite materials in the construction industry, and the use of recycled aggregates can substitute natural ones up to 45% in Germany by producing so called RC-concrete. RC-concrete is recognized by the German Committee for Reinforced Concrete (DAfStb) and can be used like normal concrete if produced according to DIN EN 206-1 and DIN

1045-2 (Deutscher Ausschuss für Stahlbeton e. V. – DAfStb, 2010). The RC-aggregate must comply with DIN 4226-101 and DIN 4226-102. Depending on the composition of its constituents, the aggregate is divided into four different types. Types 1 and 2 can be used for concrete production without an additional structural analysis, while types 3 and 4 are subject to additional special technical specifications and may not be used in the production of concrete according to DIN EN 206. This research focusses on Type 1 and 2.

### *The Use of RC-Aggregates for Precast Production*

In the CE approach, reuse takes precedence over recycling, and precast concrete products are particularly well-suited for reuse. Precast concrete is placed in formwork and cured directly after production at the concrete plant, and the resulting precast concrete elements are delivered to construction sites after production for installation. Considering the principles of the circular economy, the use of precast elements has many advantages. (1) At the end of their primary use, they can be reused and do not necessarily need to be recycled (Asam, 2007; Harala et al., 2023; Küpfer & Fivet, 2021). To remove and reuse precast products without damage, design for disassembly must be planned for in compliance with product requirements and regulatory building codes while maintaining aesthetics (Mettke et al., 2019). (2) Precast elements can facilitate selective deconstruction if design for disassembly is considered in the design phase (Eschenbach et al., 2023). (3) Precast elements can be tracked in BIM-based databases to facilitate reuse at the end of a building's life (Eschenbach et al., 2023). (4) According to German law, 'National technical approval' can be granted for products that do not comply with DIN regulations, and precast elements can be produced with higher recycling rates or other aggregate types (DIBt, 2021). For the stated reasons, precast RC concrete is a circular economy business model that extends the life of building products. With the reuse of precast products, value and production chains are closed, promoting circular economy and contributing to decarbonization.

## Methods and Results

### *DIN Norm Evaluation*

To evaluate which precast elements can be produced with RC-concrete the DIN standards applicable to the respective precast concrete elements are analysed and the relevant parameters are compared with the current regulations for the use of RC-concrete. Therefore a rating system is introduced, rating the individual products from 0 (not suitable for the production with RC-concrete) to 1 (suitable for the production with RC-concrete). The rating categories are as followed:

**C1. Prestressed concrete:**
RC-concrete may not be used in prestressed concrete (Deutscher Ausschuss für Stahlbeton e. V. – DAfStb, 2010). Precast concrete products which are often produced in prestressed construction, but which are also approved for production with standard concrete, are rated 0,5, since the production of these precast concrete parts with RC-concrete would be possible, but is not allowed in the common production method. Products, which are not commonly produced with prestressed concrete, are rated 1.

**C2. Compressive strength:**
Construction with RC-concrete is permitted in Germany up to the compressive strength class of C30/37 according to DIN EN 206. Precast concrete elements that have a compressive strength requirement of at least C35/40 can be excluded, since a maximum compressive strength of C30/37 is permitted for RC-concrete. Precast concrete elements that must achieve minimum compressive strengths of C30/37 are rated 0,5. That requirement severely restricts the field of application for RC-concrete, which might make production with RC-concrete unattractive for concrete manufacturers. Products with required maximum compressive strength classes lower than C30/37 are rated 1.

**C3. Exposure classes:**
The exposure class indicates the actions to which the concrete is exposed during its life cycle. According to the DAfStb guidelines, a recycled aggregate may be used for exposure classes with moderate risk of corrosion and

attack. In the case of possible chloride effects due to contact with road salt (XD1) or salt water (XD2) and mechanical wear (XM1-XM3), recycled aggregate must not be used (Deutscher Ausschuss für Stahlbeton e. V. – DAfStb, 2010). Figure number 1 shows the

possible applications of RC-concrete in conventional house construction and the respective exposure classes. Products, which are used in both, possible and non-possible, exposure classes, must evaluated individually for each project, are rated 0.5. Products which are usually build within the context of the exposure classes which do not require adjustments are rated 1.

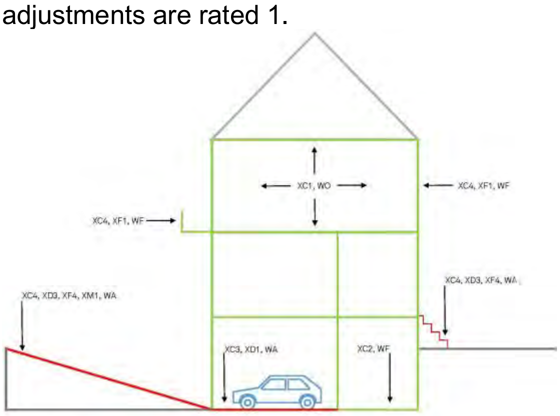

**Figure 1. Possibilities for the usage of RC-concrete in residential buildings depending on the exposure classes. green indicates RC-concrete is possible, red indicates RC-concrete is not possible, XC1: dry or constantly wet; XC2: wet, rarely dry; XC3: moderate moisture; XC4: alternately wet and dry; XD1: moderate moisture; XD3: alternating, wet and dry; XF1: moderate water saturation, without de-icing agents; XF4: high water saturation, with de-icing agents; XM1: moderate wear stress; WO: concrete which after normal curing no longer remains wet and after drying out during; WF: concrete that is damp frequently or for a long period of time during use. or for a prolonged period of time during use; WA: concrete that, in addition to the exposure by class; WF: is exposed to frequent or prolonged alkali supply from the outside. © (Heuser & Jegen, 2023).**

The ratings in the categories are then multiplied. Therefore, if one of the categories is rated with the value of zero, the precast element total value is zero, as they are not suitable for the production with RC-concrete.

The evaluation shows that most parts in a prefabricated building can be built with RC-concrete. Table number 1 presents the results for each product type. Precast concrete products rated 0,5 or above are suitable for the production with RC-concrete and can, in most cased, be used without further examination. Those precast concrete products are wall elements, blocks and foundation elements. Precast concrete products ranked 0,25 might also be produced with RC-concrete, but only if not build with pre-stressed concrete. Those products ranked lower are suitable for the use with RC-concrete in general, but it requires additional examination of the element's exposure classes. This product is the stairs, which can be used indoor without further checking, but cannot be used outdoor as it is exposed to chloride, de-icing agent and alkali.

| Precast concrete products | Product DIN-Norm | C1 | C2 | C3 | Total |
|---|---|---|---|---|---|
| Hollow core slabs | DIN EN 1168 | 0,5 | 1 | 1 | 0,5 |
| Foundation piles | DIN EN 12794 | 0,5 | 0,5 | 0 | 0 |
| Ribbed floor elements | DIN EN 13224 | 0,5 | 1 | 0,5 | 0,25 |
| Linear structural elements | DIN EN 13225 | 1 | 1 | 1 | 1 |
| Floor plates for floor systems | DIN EN 13747 | 0,5 | 1 | 1 | 0,5 |
| Precast concrete garages | DIN EN 13978 | 1 | 0 | 1 | 0 |
| Stairs | DIN EN 14843 | 1 | 0,5 | 0,5 | 0,25 |
| Foundation elements | DIN EN 14991 | 1 | 1 | 1 | 1 |
| Wall elements | DIN EN 14992 | 1 | 1 | 1 | 1 |
| Beam-and-block floor systems | DIN EN 15037 | 0,5 | 1 | 1 | 0,5 |
| Retaining wall elements | DIN EN 15258 | 1 | 1 | 1 | 1 |
| Normal weight and lightweight concrete shuttering blocks | DIN EN 15435 | 1 | 1 | 1 | 1 |

**Table 1. Evaluation Matrix. (DIN Deutsches Institut für Normung e.V., 2005, 2007a, 2007b, 2007c, 20.2008, 2008, 2009, 2010, 2011a, 2011b, 2012a, 2012b, 2013, 2017).**

*Material Flow Analysis*

The demand for recycled aggregates for the concrete production of prefabricated houses is a crucial factor for the establishment of the presented circular economy application. The basis for this approach is the average floor area of built prefabricated houses per building type in $m^2$ in the years 2017 to 2022 (Statistisches Bundesamt, 2023). Also a specific Material Capacity Index (MCI) for different building types was defined. The MCI is the relation of the average amount of concrete of a specific building types to the specific average net floor area of the database of IöR (IÖR-Forschungsdatenzentrums, 2023). The considered building types are (1.) Domestic building: one and two-family houses, multi-family houses (2.) Non-domestic-building: institutional buildings, office and administrative buildings, agricultural service buildings, factory and workshop buildings, retail and storage buildings, hotels and restaurants, other non-agricultural service buildings, other non-domestic buildings.

To determine the required amount of concrete, the specific MCI is multiplied by the average net floor area per building type. The calculated mass of concrete is multiplied by a concrete density of 2,400 kg/$m^3$ to determine the required amount of concrete in tons (Neroth & Vollenschaar, 2011). 1,950 kg of concrete aggregate are assumed per cubic meter concrete construction to determine the required total amount of aggregate.

For different exposure classes accordingly mass percentages of recycled aggregate may be used instead of natural aggregate. This is considered in the determination of aggregates' quantity. The average value of all maximum permissible mass percentages of the exposure classes is assumed, which is calculated to be 37.5% for aggregate type 1 and 30% for aggregate type 2. In addition the required amount of RC-aggregate is calculated if the total amount of natural aggregates is substituted. This would apply if precast fabricants demand national technical approval for their products and hence show that the total substitution is feasible.

The material flow analysis shows that 14,877 kilotons of aggregate are needed per year to build all prefabricated houses in Germany with concrete. To evaluate how many RC-aggregates are needed different distributions of the RC-aggregate type 1 and RC-aggregate type 2 are considered. If only RC-aggregate type 1 is used 5,021 kilotons of concrete and 558 kilotons of bricks and klinker are needed. If only RC-aggregate type 2 is used the demand for concrete, bricks and klinker will shift. On the one hand the need for concrete will decrease to 3,124 kilotons, on the other hand the demand for bricks and klinker will rise to 1,339 kilotons. An equal distribution of the RC-aggregate types will result in 4,072 kilotons of concrete and 948 kilotons of bricks and klinker. The amount of RC-aggregates including bricks and clinker increases with the use of RC aggregate type 2 as well as the total amount of RC-aggregate decreases.

Considering a total substitution of natural aggregates the demand for RC-aggregates is 14,877 kilotons. If only RC-aggregate type 1 is used 13,389 kilotons of concrete and 1,488 kilotons of bricks and klinker are needed. Considering the usage of RC-aggregate type 2 only, the demand for concrete will decrease to 10,414 kilotons while the demand for bricks and klinker will rise to 4,436 kilotons.

An equal distribution of the RC-aggregate types will result in 11,901 kilotons of concrete and 2,975 kilotons of bricks and klinker. The amount of RC-aggregates made with bricks and clinker increase with the increase of the use of RC-aggregate type 2. The total amount of recycled aggregates over the different distributions stays the same, as natural aggregates are fully replaced. The required amounts of CDW could potentially be covered by the occurring CDW in Germany.

## Conclusions

The construction industry is a significant contributor to global greenhouse gas emissions and waste generation. To address these challenges, a circular economy approach has been introduced. In general CDW recycling is already established in Germany. However, the concept of circular economy is based on optimizing material cycles through efficient resource use, extended service lives, and closed-loop recycling. Reuse takes precedence over recycling, and precast concrete products are particularly well-suited for reuse. By removing and reusing precast products without damage, value and production chains are closed, promoting circular economy and contributing to decarbonization. This research shows that most precast products used for building construction can be produced with RC-concrete. It also demonstrates that the RC-aggregate for this approach can be fulfilled by the occurring CDW in Germany. Further research will include a comparison to other countries, to make the results usable outside of Germany.

# Business models for sustainability impact, not potential: A literature review of the life-cycle impacts of business model strategies

**Emma Johnson**[(a)]
a) International Institute for Industrial Environmental Economics, Lund University, Lund, Sweden

**Keywords**: Sustainable business models; Life cycle assessment; Rental; Impact assessment; Business models for sustainable transformation.

**Abstract**: The concept of sustainable business models (SBMs) has received increasing attention as research, policy, and industry acknowledge the need to change current production and consumption practices. Research has focused on the conceptual aspects and potential of SBMs rather than their actual impact. There is a need to understand whether SBMs have less impact on society than conventional business models, and in what context and conditions can SBMs reduce impact. This research conducted a systematic literature review of comparative life-cycle assessments (LCAs) of SBMs and conventional business models to identify factors of SBMs that are significant and sensitive toward their environmental potential. Of the studies evaluating the life-cycle impacts of stated SBMs, rental was the most common strategy for several product categories to facilitate sustainability ambitions. Rental was facilitated through different customer-business relations: pay-per-use, pay-per-time period, pay-per-event, pay-per-result, and pay for products bundled with services. The life-cycle impacts were aggregated and compared for the different business model rental activities, highlighting sensitive business model factors that play a key role in determining the potential to reduce the environment impact in SBM strategies. These factors include rental infrastructure, customer and service transport to the business, product usage, product longevity and durability, length of rental periods, and customer education and involvement. SBM strategies do not offer an environmental benefit in all cases, as it is dependent on the context, various scenarios, environmental indicators, and unit utilized to asses. This research provides guidelines for key elements to test in sustainable business model design, and emphasizes the need for prospective LCAs or evaluations of proposed SBMs prior to their implementation to support optimal business model design for environmental outcomes.

## Introduction

The concept of sustainable business models (SBMs) has received increasing attention as research, policy, and industry acknowledge the need to change current production and consumption practices. SBMs have the intention to create, deliver, and capture value to maintain or contribute positively to the environment and society outside of its organizational boundaries (Schaltegger et al., 2016) through its activity systems (Zott et al., 2011).

SBMs often focus on moving away from intensive resource consumption and the sale of products towards services or solutions. They are often recognized or stated as synonymous with business models for sustainability (BmfS), product-service systems (PSS), circular business models (CBMs), and sharing business models. Although these business models vary in the way they operate, they do have the common ambition to reduce resource use. They also often employ the same strategies such as rental, and activities of reuse, repair, remanufacturing, refurbishment, recycling, and others.

Since business models include the organizational architecture (Teece, 2010) that guide how products are produced and consumed (Wells, 2013), it is important to analyze their structures and the implications of the services offered, not only the sustainability of products themselves (Kjaer et al., 2019; van Loon et al., 2021). Service design parameters, such as how the business model is structured, can have more consequences than physical product design parameters (Allais & Gobert, 2017).

There is a lack of evidence of the sustainability impacts of SBMs in comparison to conventional business models, as previous research has focused primarily on the potential of SBMs (Brehmer et al., 2018), rather than their actual impact (Fichter et al., 2023).The impact of SBMs are complicated by the various configurations or business model patterns of SBMs, where there are several parameters of a business model set-up with different significance for an SBM's impact. Böckin et al. (2022) highlight the need to understand whether SBMs have less impact on society than conventional business models, and in what context and conditions do SBMs provide environmental benefits.

While previous research has stated a lack of quantitative methods (Kjaer et al., 2016; Pieroni et al., 2019) and appropriate tools to assess the complexity of SBMs (Böckin et al., 2022; De Giacomo & Bleischwitz, 2020; Goffetti et al., 2022), life-cycle assessment (LCA) has been noted as an important method to evaluate products and services as it helps to avoid impact shifting in a life cycle (Finnveden et al., 2009), and allows the comparison of different product systems (Baumann & Tillman, 2004). In a study comparing several other environmental assessment methods, LCA was found to be the most complete method to use to measure circularity, due to its many different indicators (Elia et al., 2017).

This paper compares the life-cycle assessments of various SBM strategies, and outlines the business model factors that are key to reduce the life-cycle impacts from production and consumption in SBMs for different industries.

## Methodology

A systematic literature review was conducted to identify different SBMs and to understand how and what impacts have been assessed. Thirty-two configurations of keyword strings were tested in three databases to find relevant results and a processable number of results.

> Selected search string:
> ( "sustainable business model*" OR "business model* for sustainability" OR "product service system" OR "circular business model*" OR "sharing business model*") AND (" impact" OR "environmental impact" OR "social impact" OR "economic impact" OR "indicator" OR "assessment")

Several phases of screening were conducted to further scope the results, initially to studies conducting an evaluation of the environmental impacts of an SBM (n=39), then further scoped to identify peer-reviewed studies that conducted an LCA comparing an SBM and a conventional business model (n=13). Selected studies included LCAs that were comparable (same product types and functions but different business model structure around them). Comparison served as a reference point of whether the evaluated SBM had a higher or lower impact. Included studies also had to include a functional unit for assessment transparency. Evaluated SBMs also had to have a stated sustainability intention; business models advocating for example for lean manufacturing with sustainability objectives were not included. Figure 1 illustrates the geographic spread of the included assessments.

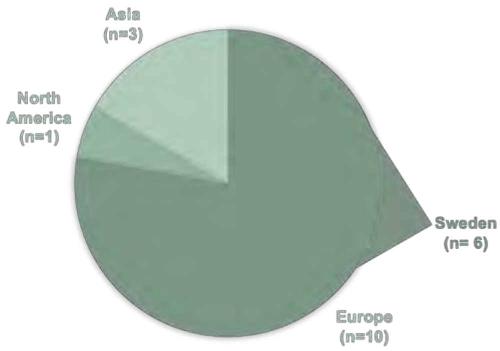

**Figure 1. Geographic spread of assessments.**

## Results

*Assessments of SBMs*

Analyzing the impact for SBMs from the selected literature is understood by LCA environmental indicators or impact categories. While not all studies utilized the same indicators, many of the same were used. Figure 2 illustrates the most commonly utilized indicators across the studies. Impacts for the indicators often differed for the same scenarios within a study, meaning for example that while rental reduced impacts for mineral resource scarcity, as in the study by Martin et al. (2021), it had increased GHG emissions. An overall evaluation of SBM strategies cannot be given, as understanding the impact of one business model over the other by aggregating the impact into a single score is not methodologically advised since it can overlook the impact of individual indicators and requires subjective weighting (Bjørn et al., 2020).

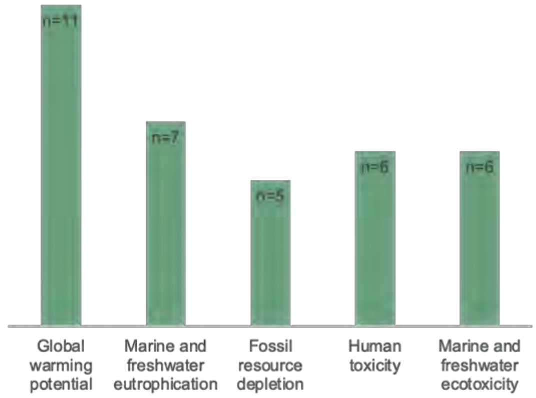

**Figure 2. Most common evaluated indicators in the included assessments.**

Of the studies evaluating the life-cycle impacts of stated SBMs, rental was the most common strategy to facilitate sustainability ambitions. Sales with the addition of services was another common strategy evaluated. Rental and additional services typically included repair, maintenance, remanufacturing, take-back and reuse. The SBMs engaged in these activities with the ambition, in most of the analyzed studies, to extend product lifetimes, but also with commonly cited benefits for product-service systems such as reducing material requirements and fulfilling customer demands through fewer products.

*The impacts of SBM strategies and activities*

SBM strategies were facilitated through different ways of offering products to consumers, as shown in Figure 3. The analyzed studies are spread across various product categories, different business model strategies, and sales relationships. Insights into examples of the impacts of different SBM strategies are described and triggering factors are identified in the following sections. Table 1 in the Appendix provides details of the studies evaluated.

**Pay-per-use models** to facilitate rental was a common strategy of SBMs, these imply relatively short-term, one-off rentals where the customer paid for the use of products. Pay-per-use processes were the most commonly evaluated for B2C business models and with consumer goods. This covered consumer goods such as pancake machines, battery-powered chainsaws, books, and formal wear. It also included goods for mobility such as dockless e-scooters and cars, and industrial applications of lithium-ion batteries.

For pancake machines, transport was the most impactful factor that rendered the rental system to have a higher impact than conventional sales (Allais & Gobert, 2016). In the case of chainsaws, a traditional sales model with product lifetimes of 10 years had a higher impact than rental with product lifetimes of 4 years for several indicator categories. This was due to the distributed use and the reduced need of production. While product lifetime played a significant difference for sales scenarios, changes in lifetime of the product in rental did not have a difference in most indicator categories—rather the largest impact of rental came from transport needed for maintenance (Martin et al., 2021). Transport was also a key factor in the rental of books, as Amasawa et al. (2020) found that if more than a few kilometers were traveled by car to share books with a few people, then rental had higher impact than sales and ownership. For formal dresswear, the impact varied between indicators as well as the functional unit. For one indicator category, freshwater ecotoxicity, dresses sold traditionally had a lower impact than rental when measuring one average use, but for the same category, rental had lower impacts compared to sales if assessing the business model by the number of dresses it should provide over a time span. This was due to the high impact of cleaning and traveling needed to facilitate rental, and differences in the scope of measurement (Johnson & Plepys, 2021). Travel was also an important factor for dockless e-scooters, where owning a scooter was less impactful than rental due to the longer lifespan in ownership, and no collection or deployment needed for e-scooter rental (Moreau et al., 2020). In a pay-per-use model of cars in a B2C company, rental had the same impact as conventional sales. In a peer-to-peer rental of cars, ridesharing only had a lesser impact than conventional sales if the trip had at least three passengers and if less than half of the distance was spent detouring. Peer-to-peer rental in the form of ridesharing was better than car sharing since it was assumed of people traveling in the same direction (Amasawa et al., 2020). For lithium-ion batteries with pay per kwh application in automotive manufacturing, strategies of repurposing, remanufacturing, and recycling all had lower impacts than the production of new batteries. Repurposing had the greatest benefit for reduction of carbon dioxide emissions over the other strategies, but had a greater impact on resource depletion, although all were better than new production and sales (Schulz-Mönninghoff et al., 2021).

**Pay-per-time period** was another common strategy used by SBMs, this includes customer-business relations such as subscriptions, access to products for a specific time period, and flexible leasing models. This included a subscription model with consumer goods such as prams, as well as clothing. Pay-per-time period also included regular fees for a long period with energy-using industrial equipment such as air separation equipment. Leasing contracts were also analyzed for residential water purifiers, and industrial equipment such as a soil compactors.

Rental of prams had lower impacts than sales in nearly all the assessed impact categories, but if conventionally sold prams were given a second-life after the first sale, then a sales model would be less impactful than rental due to the heavy cleaning cycles and transport needed to facilitate rental (Kerdlap et al., 2021). Membership to rent clothing from a clothing library was sometimes higher or lower than conventional sales depending on the clothing type and the indicator. In the case of a pair of jeans, rental with 4x the usage than conventional sales in an online store had about half of the impact for most of the indicators evaluated. The impact had less of a gap in an online store with twice the usage. Offline scenarios where customers went to the store individually (longer distances assumed) had higher impacts than online, and was nearly the same as conventional sales for some indicators (Zamani et al., 2017). Rental of residential water purifiers had higher impacts than conventional sales in some indicators, for example for abiotic resource depletion, but slightly lower impact for global warming potential, due to inefficient product-use requiring higher maintenance (Chun & Lee, 2017). Rental of air separation equipment, high energy-using products, had greater impacts than a sales model unless there were already idle products existing and/or existing infrastructure already in place, as more transport was needed (Zhang et al., 2018). In the case of rental for soil compactors, leasing had less of an impact than a sales model due to the remanufacturing and repainting that increased the product lifetime (Lindahl et al., 2014).

**Pay-per-event** is similar to pay-per-time period as well as pay-per-result or even pay-per-use strategies. Rental of a beach flag and an event tent for a specific event had lower impact than

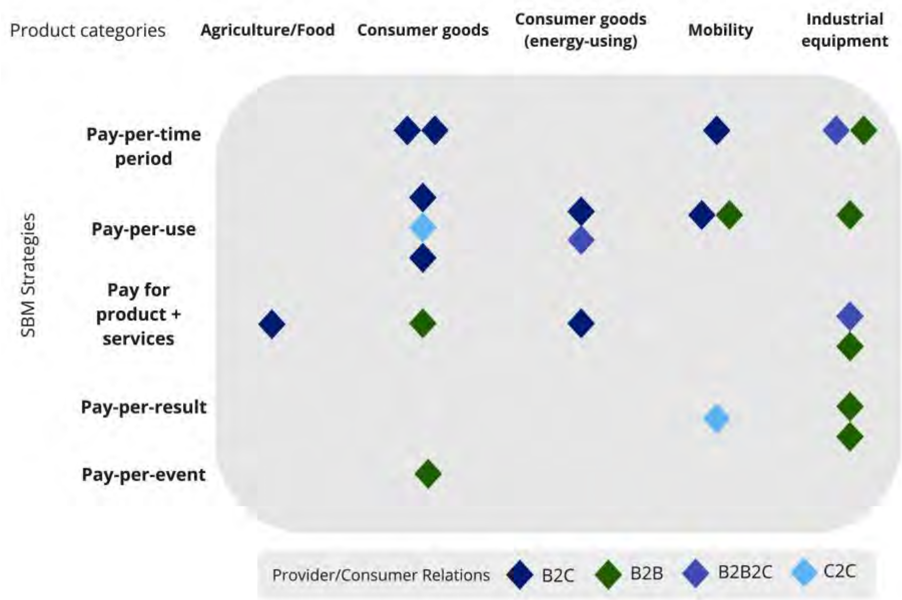

**Figure 3. Overview of evaluated SBMs.**

a conventional sales model since products were used just once before their end-of-life, and production had the highest amount of impacts (Kaddoura et al., 2019).

**Pay-per-result** business models sell a solution or result that offer a particular outcome. Studies that evaluated this strategy in SBMs only included industrial equipment. An SBM offering air separation equipment with a pay-per output model had greater impacts than a sales model due to extra processes needed such as pipeline building and transportation of gas (Zhang et al., 2018). The impact of a building exterior cleaning system as a service, however, was found to be less impactful than a normal sales model due to improvements in the timing and resource-efficiency of the service (Lindahl et al., 2014).

The sale of **products and services** as a SBM strategy includes bundled products with particular services, primarily maintenance. For example, the sale of a recycling bin, locker, and waste inlet system was sold along with services of repair and maintenance. The sale of the products and services had lower impacts than conventional purchasing and replacement, as the services increased the lifetime of the products for the recycling bin and the locker, which had high production impacts (Kaddoura et al., 2019). The sale of core plugs for paper mills along with the services of takeback and reuse had a lower impact than traditional sales due to the extended lifetime of the plugs (Lindahl et al., 2014). However, the sale of air separation equipment and additional services (infrastructure construction and training services) had the same impact as a conventional BM (Zhang et al., 2018).

There was one study of an SBM strategy of **direct purchasing.** Ugly produce was sold, where the environmental aspect of the sale was derived from utilizing food that would have otherwise been disposed of as waste, and in which more resources to grow food would have been needed. Results of the evaluation indicated saved emissions from the food avoiding landfill, with up to three customer points of travel distance (Ribeiro et al., 2018).

### *Discussion of factors affecting SBM impact potential*

As shown in the previous section for several of the SBMs, "the environmental sustainability of alternative business models is function-specific and scenario dependent" (Amasawa et al., 2020, p. 10). Factors that most affected the life-cycle impacts of products were:

**Rental infrastructure:** The existence of rental infrastructure in close proximity to customers reduced impacts in some cases since it reduced the travel needs required for rental. However, in other cases, it increased the impacts due to the production needed to construct it, unless the lifetime is extended (ie. tool rental lockers).

**Customer transport to the business**: Distances between customers and rental stores play a large likelihood of increasing the impact, particularly for car-based travel. Transport can be reduced if businesses also offer longer leasing times, or if business could use postal logistic delivery for rentals.

**Service transport needs of the company**: Rental requires increased maintenance in several cases, implying the increased need of travel to clean products as well as repair, maintain, and collect. Service frequency can be minimized, as well as the distances of transport and the type of transport used.

**Product and parts' longevity and durability**: Product lifetime extension is important for most products, particularly in the sales model. However, product lifetime did not play as large as a role in regards to the life-cycle impacts for rental business models, as longer lifetime often implied increased maintenance and travel needs. Product lifetime is particularly important for goods that have the highest portion of impacts from production and/or products that have high material durability.

**Product usage**: In rental business models, increasing the number of uses and the frequency of use for some goods such as non-energy using or low-energy using products has a higher potential to reduce impact in comparison to sales models.

**Rental periods:** Increasing the duration of rental periods could reduce impacts as it decreases travel needs.

**Customer education and involvement:** Educating consumers on how to use energy-using equipment efficiently can reduce the impacts of the product. It is also important to engage customers to participate or purchase from businesses with sustainability ambitions.

## Conclusions

Strategies such as rental, along with repair, reuse, remanufacturing, and other R-strategies have the potential to limit the life-cycle impacts of the production and consumption of products. However, this potential is dependent on specific scenarios and contexts, as well as the impact categories evaluated. There is no single configuration of an SBM or strategy that reduces environmental impacts for all environmental indicators.

The factors that render the activities of an SBM sensitive are not novel in themselves from a qualitative research perspective, however, this research on quantitative life-cycle assessments affirms these factors are important to limit the impact when designing new business models to change the way that society produces and consumes. This research contributes to the advancement of business models for sustainable transformation through the identification of key sensitive elements to guide and to test in the design of disruptive new business models.

## Appendix

| Product Category | BM relation | Product | Strategy | Functional Unit Assessed | Indicators | Impact | LCA Scope | Location | Authors |
|---|---|---|---|---|---|---|---|---|---|
| Agriculture /Food | B2C | Waste fruit and vegetables | Buy directly from farmers and deliver to consumer points | Amount of fruits and vegetables delivered once a week multiplied by the number of associates over the period of one year | Carbon dioxide equivalents | Saved emissions from avoiding landfill from the BM, even with three customer points | Cradle to grave | Portugal | Ribeiro et al. (2018) |
| Consumer goods | B2C | Prams | Subscription | Service provision of prams for 600,000 child-years in Singapore | Climate change, fossil depletion, freshwater ecotoxicity, freshwater eutrophication, human toxicity, ionising radiation, marine ecotoxicity, marine eutrophication, metal depletion, ozone depletion, particulate matter formation, photochemical oxidant formation, terrestrial acidification, terrestrial ecotoxicity, water depletion | Rental BM had lower impact in 14/15 categories with a lifetime longer than 3 years | Cradle to grave | Singapore | Kerdlap et al. (2021) |
| Consumer goods | B2C | Dress | Pay per use | one average use, user dress needs for 4 years satisfied by purchasing, user dress needs for 4 years satisfied by uses/wear occasions | Freshwater ecotoxicity potential, human carcinogenic toxicity potential, global warming potential | Rental BM's impact was sometimes higher or lower than conventional in different indicators and depending on different ways to measure the function of the product | Cradle to grave | Sweden | Johnson and Plepys (2021) |
| Consumer goods | B2C? | Clothing (t-shirt, dress, jeans) | Monthly membership fee | one average use | climate change, fresh water consumption, fresh water ecotoxicity and fresh water eutrophication | Rental BM's impact was sometimes higher or lower than conventional in different indicators. Online BM scenarios compared to offline | Cradle to grave | Sweden | Zamani et al. (2017) |

| Product Category | BM relation | Product | Strategy | Functional Unit Assessed | Indicators | Impact | LCA Scope | Location | Authors |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | | scenarios are generally more favorable for most indicators. | | | |
| Consumer goods | B2C | Book | Pay per use | One specific book read by one person in 10 years | Greenhouse gas emissions | The emissions of rental from a store and leasing from a peer are greater than those of the conventional model when a book is bought and shared with more than three people | Cradle to grave | Sweden | Amasawa et al. (2020) |
| Consumer goods | C2C | | Pay per use | | | | | | |
| Consumer goods | B2B | Beach flag, Event tent | Pay per event | One item used for one event | Global warming potential, acidification potential, eutrophication potential | Product leasing has a reduced impact than conventional sales | Cradle to grave | Sweden | Kaddoura et al.(2019) |
| | | Recycling bin | Product sales and services | 2 recycling bins (with a capacity of 85 L each) used for 15 years | | The impact of sales and the services needed to repair and refurbish products were less than conventional sales | | | |
| | | Locker | | 1 locker with 9 doors and a dimension of 300 × 300 × 47 cm used for 20 years | | | | | |
| | | Waste inlet system | | One inlet (upper part and lower part) and one door, used for 30 years | | | | | |
| Consumer goods (energy-using) | B2C | Household water purifier | Lease | Supplying hot/cold drinking water for 15 years between 1998 and 2013 | Global warming potential, abiotic resource depletion | The impact of the rental BM was sometimes higher or lower than the sales model in different indicators | Cradle to grave | Korea | Chun et al. (2017) |
| Consumer goods (energy-using) | B2C | Battery-powered chainsaw | Pay per use | Annual service of one electric chainsaw in the Husqvarna rental system | Global warming, fossil resource scarcity, mineral resource scarcity, human toxicities (carcinogenic and non-carcinogenic), and marine ecotoxicity | Rental BM's impact was sometimes higher or lower than conventional in different indicators | Cradle to grave | Sweden | Martin et al. (2021) |
| Consumer goods | B2B2C | Pancake machine | Pay per use | 400 cycles of use (i.e. initially 10 pancake | Climate change, ozone | Impacts of the rental BM are greater | Cradle to grave | France | Allais and Gobert (2017) |

# Environmentally responsible customer solution design for small-scale businesses

**Mirja Kälviäinen[a], Kati Kumpulainen[a], Anna Palokangas [a], Enna Eloranta [a]**
a) LAB University of Applied Sciences, Lahti, Finland

**Keywords**: Business responsibility; Sustainable consumption; Design tools; Service design; Behaviour change.

**Abstract**: The requirements for environmental business responsibility have shifted from reduced environmental harm and resource use in production to include the low environmental impact of the products and services in use. The requirements for consumption change are especially evident in fast fashion. This paper discusses development tools that support creating environmentally responsible offerings for the customer use phases in small-scale businesses. The aim of the tools is to support SMEs to design customer-oriented environmental responsibility by utilizing systemic design, customer-driven design principles, service design, user research-based design guidelines and design drivers, and design for behaviour change tools. A systemic design type of loop canvases enables the modelling of low-impact consumption, distribution and production. Four customer personas present the various sustainable consumption profiles. Other customer-driven design tools for environmentally responsible product and service solutions have been collected and edited to use as tools to analyse possibilities of the customer journey to lower the consumption impact of offerings and change behaviours during customer journey. A benchmark, development analysis and co-creation sessions during the creation of the development tools also tackled the challenges arising from the clothing sector businesses. The development canvases and behaviour change tools presented provide support for clothing businesses in creating sustainable services that cover a wide set of behaviours around clothes in everyday life and can consider the identity and social aspects of consuming clothes in addition to circular aspects.

## Introduction

Solutions to the ecological sustainability crisis require a reform of economic operation models including a change towards low impact consumption patterns (Lettenmeier et al., 2019, p. 4-5). The business requirements for environmental responsibility have shifted from merely reducing the environmental harm of production and distribution to including low environmental impacts arising from the customer-user processes. One major phenomenon of overconsumption is the unnecessary use of fast fashion. The environmental impacts of consumption in developed countries should be reduced by 70% by 2030 and 90% by 2050 if we are to stay within the 1.5-degree global temperature rise (Lettenmeier et al., 2019, p. 4-5). Despite of the growing trends towards environmentally sustainable consumption consumers are unwilling to lower their requirements and enjoyment from consumption (Greene & Korkman, 2022). Additionally, many consumer barriers exist distracting and preventing consumers from environmentally sustainable consumption (Gleim et al. 2013). Businesses can support consumers to make the needed changes in consumption behaviour.

The LAB University of Applied Sciences in Finland created a set of development tools has been for SMEs for the low impact customer behaviour design in two overlapping projects focusing on responsible and effective product and service development. The development tools include systems thinking, customer-driven design principles with customer personas and a customer journey, and tools to assist in designing for behaviour change. In addition to business interview data, benchmarks and expert consulting, the material applies earlier gathered and tested collections of customer-driven design tools for environmentally responsible solutions. The array of materials includes qualitative user research-based design guidelines, service design, and behaviour change tools (Kälviäinen, 2022; Kälviäinen, 2021; Kälviäinen, 2019).

The drafting and editing of the tools for the SMEs was based on regional business manager interviews in spring 2022, business benchmarks in spring 2022 and a series of lectures and co-design training sessions during the spring and autumn 2022 and spring 2023. In spring 2022 also a special training session day was conducted for clothing companies where the already existing tools were tried out with the participants.

The businesses demonstrated a lack of customer-orientation but interest in customer understanding. Many saw questions of environmental responsibility as big and challenging and faced difficulties in communications concerning environmental responsibility. There were a lack of customer studies providing extended understanding about the pre-, during- and post- stages of the customer journey.

For these reasons, the requirements for the design guidance and tools included ease of use. This led to a quest for inspiration from gamified learning solutions with a storyline that was meaningful and interacted with each business case in small steps. The nature of the tools at hand also pointed to game tools: systems describing canvases, customer personas resembling game roles, visual process descriptions, design guidelines and ideation cards.

To avoid too much of a cognitive load the material was divided into sections:

1. The basics of customer-driven environmental sustainability for businesses, different types of sustainable consumption profiles, a start-up analysis of the current business situation and a selection of a baseline customer persona.
2. The basics for a customer-driven approach, a customer journey tool, sustainable consumer trends, different motivational and behavioural consumer profiles, a customer journey analysis with environmental impact areas and developing a realistic customer persona.
3. Service and product redesign instructions with low environmental consumption impact advice, barriers and hindrances to this, and drivers for sustainable consumption. Redesigning the basic customer journey into an environmentally low-impact form that integrates behaviour change psychology with the drivers for sustainable consumption.
4. Communication about the solutions with justified, transparent, understandable, and motivating way.

## The loop canvases for systemic thinking

A benchmark analysis in spring 2022 scanned national Finnish and international business offerings that support environmentally responsible activities of customers. Systemic double and triple loop canvases emerged by analysing these examples. The double loop canvas describes a simple consumption-production system and the triple loop canvases make it possible to model multi-level operations of co-working companies, distribution companies and platform companies offering recycling or customer peer-to-peer services.

These tools support systemic modelling for a low-impact consumption, distribution and production system (Figure 1). They describe the actions of the companies and the customers in parallel demonstrating the current situation and the possibilities of consumption-production responsibility for businesses. On the right side, the model considers the business offering's customer-users, indicating the service moments where the solutions can reduce the environmental impact of the customer. In the middle the activities of the distribution company are considered, and on the left activities in the production. After the redesign of the customer service the canvases provide the possibility to analyse the demands of low impact customer-orientated solutions on distribution and production.

**Figure 1. Triple loop description of the consumption, distribution, and production system (figure by Enna Eloranta and the project group 2022).**

The loop models help businesses to build a basic understanding of how their services and products offer a flow of service moments and interactions. The loop canvases are also a tool to demonstrate circular economy business models for product offering based companies with sharing platforms, products as services and product lifecycle extensions (Sitra & Deloitte, 2022). The purpose of the loops is to help the businesses to change their perspective from business-centred environmental sustainability to the customer journey and customer process point of view.

## The customer profiles and persona creation

The customer-driven perspective is vital in designing solutions for low-impact environmental consumption. As the customer-driven development process should begin from an understanding of customer motivation and activities, the customer personas help considering these with the business offerings.

A change towards environmentally responsible desires and expectations in terms of sustainable choices was clearly visible in 2022 (Accenture Interactive, 2022; Euromonitor International, 2022; Greene & Korkman, 2022). Greene's and Korkman's (2022) global research illustrates a consumption shift from the satisfaction of needs and desires to adequacy-based consumption, although the pleasure of consuming still exists. Consistent findings in consumer research about the attitude-behaviour gap are also relevant: consumers' have nature-positive attitudes towards environmental responsibility, but in practice they do not behave in a responsible way (White & Habib, 2018, p. 9).

Consumer research has demonstrated different types of consumer motivations and actions on the questions of environmental sustainability. Customers expect companies to support their own changing needs for low-impact consumption and to provide products and services based on their sustainability values. A chart consisting of variations of consumer profiles was created to support developing the offerings from a diverse customer perspective. It was created by combining information from several earlier, especially Finnish studies (Kälviäinen 2022, p.80-103; Kaitosalmi et al., 2021; Salonen et al., 2014). This consumer profile chart provides four stereotyped personas to represent differences in sustainable consumption (Figure 2).

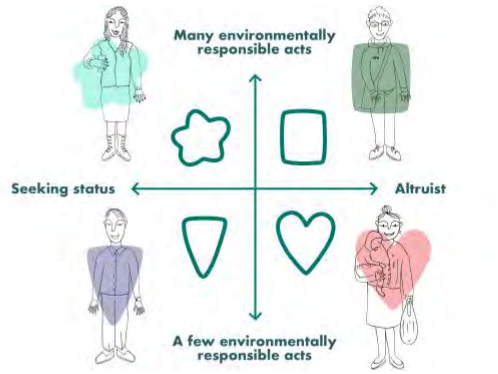

**Figure 2. A four-fold field for different consumer profiles and consumer persona examples for environmentally sustainable consumption (figure by Meri Kirjavainen and the project group 2022).**

In Figure 2 the upper part represents consumers who perform many environmentally responsible acts and the lower part those who do few. The left part represents self-image and status concerned consumers and the right part shows those who care for close others or even for the whole planet. The left upper corner stereotyped persona is a young eco-chic person who uses small, trend-based sustainable solutions. The right upper corner represents an environmentally committed adult student. The left lower corner presents an elderly man using status-related sustainable technology solutions, and the lower right corner a family-oriented mother engaged in some sustainable acts connected family benefits.
The businesses can select one persona closest to their own customers from these descriptions and start developing more accurate customer personas from that.

## The customer journey canvas

The customer journey provides a specific tool to design an offering that supports low-impact customer behaviour. The service moments in the customer journey present the various opportunities for the reduction of the customer's environmental burden. With the loop canvases business developers can mirror their current customer journey against the phases of pre-, during and post-service. Then they start analyse their offering on a customer journey canvas to observe the environmental impact of the service moments in their business. Relevant consumer behaviour advice on low environmental impacts can then be used to design changes to the current customer journey. The advice is presented from studies of consumer-based carbon emissions and as advice collections attached to a carbon footprint calculator (Salo & Nissinen, 2017; Impiö et al., 2020). The means to reduce emissions due to consumption include reductions in accommodation, mobility, food, and product related environmental impacts (Salo & Nissinen, 2017, p. 14–22). Many of these occur not only in the core service use but in the pre- and post-service use phases.

The gap between consumers' environmentally positive attitudes and less responsible choices and behaviour is influenced by consumer interests, busy everyday life, emotional biases in decision-making, and lack of individual capabilities (Kälviäinen 2022, p. 155–162). Saturated markets offer an overflow of marketing and choice where information about responsible solutions is difficult to find and understand, and the messages feel contradictory and confusing (Kälviäinen 2022, p. 180-195). Consumers need service solutions that are interesting, desirable, easy to find and understand, integrate smoothly into their everyday lives, and offer support, help and rewards in the habit changes (Kälviäinen, 2022, p. 209–211). Behavioural psychology explains the behaviour change using the COM-B model, where the factors of capabilities, opportunities, and motivation all need to come together as a support for certain behaviour (Mitchie et al. 2011; Bucher, 2020).

Figure 3 explains the consumer journey with COM-B factors where the required support for crossing the barriers and providing support can be embedded for a new, low impact customer journey covering the pre-, during-, and post-service stages. The idea is to use the canvas so that the new customer journey is made motivating, findable, easy and suitable for the customer persona created. It is possible to integrate interventions with service moments and touchpoints to both overcome obstacles and to boost customer interest (Kälviäinen, 2022, p. 6). Figure 3 is marked with the consumer persona symbols including business examples of the service moments and touchpoints suitable for each symbol owner type.

**Figure 3. The customer journey with the COM-B model containing service moments and symbols for customer persona related examples (figure by Kälviäinen and the development team 2022).**

The design can also apply psychological heuristics for behavior change (e.g. Lockton, 2010). Advanced ideas for service moment and touchpoint interventions are based on psychological decision-making heuristics and biases that can be used to support behaviour change (Kälviäinen 2022, p. 22-30; Lockton, 2018). The point is to offer an edited range of these in a form where advice is attached to suitable pre-, during- and post-service phases. The selection considers the need to build support for behavioural change as a process (Kälviäinen, 2021). The pre- phase is important for raising interest and the last phases are important for the formation of new habits.

The feedback for the new solution design is offered in the form of guidelines for low impact, customer-driven solutions (Kälviäinen, 2022, p. 217-219). These guidelines serve as memory cards to check if the solution fulfils the advice given. At the end of the design section the results are further transported to the initial loop canvases, where the consequences of the change in the customer journey can be applied to the distribution and production of the offering. The fourth section of the material uses the achieved design solution as the basis for communication.

## Conclusions: the takeaways from the tools for the clothing businesses

The benchmark, the development analysis and co-creation sessions tackled the business challenges in the clothing sector. The development tools for environmentally low-impact services provide support also for these businesses to create sustainable behaviour solutions. It is important that the development does not concentrate only to the issues such as the circularity of the material product but comprises the whole customer journey, the service moments and touchpoints where environmental impacts occur and can be avoided. The customer journey enables examining the consumption effects around the product to avoid unintended consequences in new circular business models. The guiding material created also asks the basic question of if and how the business offering corresponds to adequacy-based consumption.

Exploring the customer journey forces to examine the different service moments and consider what the customer does at that point and the environmental impacts each of them causes and how to avoid these. Touchpoints even force to a deeper examination of the details of the service. The service moments around clothing use include all the different areas of consumption that cause environmental impacts. The service design point of view also considers the service style, which can be influential in making the solution socially acceptable and is concerned with personal identities.

One area of environmental consumption impact involves accommodation, where an excess of clothes leads to too much space for storage that should be avoided. So different modular or other solutions decreasing the amount of clothes are advisable even from this consumption point of view. The washing of the clothes is another major factor to consider concerning the environmental impacts of the clothes. The energy and chemicals used for washing, or whether the washing is necessary at all, can be one means for decreasing the consumption impacts. Large consumption impacts come from mobility, so the customer journey should consider how the service is situated for low impact travel or how the clothes are transported in the customer process. One might think that clothing has nothing to do with food, but such solutions as Relove shops have combined food with shopping of used clothes, since a shopping experience with social activities is an important part of the interest around clothing.

Circular economy business models suggest many solutions to prolong product lifetimes and use efficiency with the opportunities concerning the care, repair, renting and reutilizing of clothing. All these solutions specifically require a service process, where the capabilities should be ensured, and behaviour change of new tasks for the customer should be designed and made easy. Such service solutions as renting and reselling produce specific problems with clothing since clothing is connected to style (aesthetic pleasure, social acceptance and identity questions), and the variation of sizes and body forms that should be taken into account.

A customer-driven attitude can help in ideating different, motivating solutions for specific consumer groups. Not all solutions match the desires, meanings, capabilities, and opportunities that different consumers have. With clothing, our nearest physical environment, self-image and identity issues, and social acceptability are especially sensitive issues to consider when creating offerings that would become desirable.

## Acknowledgments

This research and development work was conducted by the LAB UAS Institute of Design and Fine Arts during the years 2022–2023 in the Coaching for Responsible and Effective Product and Service Development project and in the Anticipating Responsible Service and Product Development project. Both projects are funded by the European Commission Social Fund distributed by the Regional Councils the first one by that of Päijät-Häme and the second one by that of South Karelia.

# Consumption patterns of construction workwear and circular strategies to prolong its lifetime

**Marianna Lena Kambanou[a], Karin Gagnerud [a], Mattias Lindahl[a]**
a) Linköping University, Department of Management and Technology, Linköping, Sweden

**Keywords**: Circular business model; Textile industry; Overconsumption; Circular strategy; Uniforms.

**Abstract**: The textile industry is characterized by unsustainable consumption patterns so circular strategies are being implemented to reduce consumption and waste. Workwear is a significant part of the textile industry but has received little attention from the research community. The aim is to describe the consumption patterns of a specific segment of the workwear industry i.e., construction workwear and explore circular strategies that prolong its lifetime. Data is collected through two sets of interviews, one with construction companies and one with companies in workwear industry and analyzed based on seven circular strategies: Refuse, Rethink, Reduce, Reuse, Repair, Refurbish and Remanufacture. The research is conducted in Sweden where employers usually provide clothes to employees. Concerning consumption patterns, the main finding is that workwear is usually discarded due to physical defects to the product, but workwear might also lose aesthetic and comfort value. Most construction workers wash their workwear at home, but some never wash items e.g., work trousers. The most promising circular strategy for construction workwear is repair, however, it is not commonplace. Therefore, construction companies need to set up easy-to-use processes and incentivize workers to send their clothes to repair. The lifetime of clothes has already been prolonged due to design changes in recent years and there is potential for more design improvements that can facilitate various circular strategies. Some infrequent fast fashion tendencies were noted, that should be addressed through policy and other measures. This study demonstrates that the workwear industry cannot be considered a homogeneous market, because different conditions that influence circular strategies apply to different segments.

## Introduction

The textile industry is a resource-intensive, highly polluting industry that produces between 8-10% of the global $CO_2$ emissions (Niinimäki et al., 2020). The primary culprit is unsustainable consumption patterns i.e. overconsumption (Chen et al., 2021; European Commission, 2022). Workwear is a growing part of the clothing industry (Grand View Research, 2022). However, focus has been on the fashion industry, and it is not known if this growth can be attributed to unsustainable consumption patterns (Malinverno et al., 2023). A specific workwear segment is construction workwear that includes personal protective equipment e.g. gloves, a legal requirement in many countries, and other items such as jackets etc. Many companies voluntarily provide workers with clothing to increase comfort, make them instantly recognizable and for branding purposes (Grand View Research, 2022). Moreover, in some countries there are collective agreements in the construction sector that require employers to provide workwear.

Circular economy strategies, such as sharing and reusing (Bocken et al., 2016), are being implemented to reduce consumption and waste in the textile industry and to support a transition towards a circular economy "where the value of products, materials and resources is maintained in the economy for as long as possible, and the generation of waste minimized" (European Commission, 2015). Although there has been a fair amount of research on circular economy in the fashion industry (Shirvanimoghaddam et al., 2020) and some segments in the workwear industry e.g., healthcare (Kumar et al., 2022), no study focusing specifically on construction workwear could be identified.

This research, therefore, seeks to fulfil two specific aims:

- to present data on the consumption patterns of construction workwear,
- to explore which circular strategies that prolong construction workwear's lifetime e.g., reuse, are applicable in the context of these consumption patterns.

The research is conducted in Sweden, where the use of certain types of personal protective equipment is regulated and where most employments are governed by collective agreements assigning responsibility to the employer to provide workwear.

## Research method

To meet the two research aims stated in the introduction, two separate sets of interviews are done, separately analysed, and then synthesized. Participants are informed of the purpose of the study and their participation is voluntary.

The first set consists of short interviews with construction companies to reveal workwear consumption patterns. This is a structured interview study involving a total of 25 randomly selected companies in construction, of which 14 have fewer and 11 have more than 20 employees. The interviews are conducted with workers or workwear buyers. The interview questions investigate the following areas: (i) the number of discarded work trousers per year, (ii) reasons for and attitude towards discarding workwear, (iii) washing routines for work clothes, (iv) attitude towards circular strategies. The interviews lasted 10-45 minutes and were conducted over the phone, and notes were taken.

The second set consists of 5 long semi-structured interviews with companies implementing a variety of circular strategies for workwear identified through an internet search or through the authors' networks. Company 1 has its own brand of construction workwear including a modular design that makes washing and repairing work trousers easier. Company 2 provides washing service contracts for workwear that may or may not include workwear rental. It is exploring entering the construction sector. Company 3 is a group of tailors offering repair services for all types of clothing including workwear. Company 4 and Company 5 are both primarily retailers for large construction workwear manufacturers but also offer washing services. Both encourage reduced consumption and Company 4 is in the process of setting up a repair option. Each interview lasted for about 1 hour. They were conducted and transcribed using the MS Teams software.

The data from the two sets of interviews are combined and analysed using the circular strategies framework, presented by Potting et al. (2017). They have a detailed framework of ten different strategies Refuse, Rethink, Reduce, Reuse, Repair, Refurbish, Remanufacture, Repurpose, Recycle and Recover that can be applied to products. The three last strategies are however, considered out of scope because they do not focus on prolonging the lifespan of a product but either of its parts (Repurpose) or of the materials it comprises (Recycle and Recover).

The study is limited to the construction industry and any attempt to generalize the results to other industries must be done with care. Similarly, when generalizing the results to other countries their similarities to the Swedish workwear industry should be considered. Finally, the study is also limited by the number of participants, as for example, no large workwear manufacturers were included in the study.

## Consumption patterns of workwear

In this section the results from the first set of interviews with the construction companies are presented. The interviewees provided a variety of reasons for discarding workwear and explained their attitude towards circular strategies that can prolong workwear lifetime.

### *Discarding workwear*

The number of discarded work trousers per year can be seen in Figure 1. The average is 2.3 pairs of trousers per year per worker. The reasons for discarding workwear can be categorized into two overarching groups. In the first group are the reasons connected to damage which means that the garment loses its functional properties. Damage includes ripped seams, holes in the knees and pockets, abrasions in the crotch, holes in shoes, and broken zippers and buttons etc. The second group of reasons concerns workwear losing its aesthetic and comfort properties. Workwear can become dirty or stained with concrete and paint, or can lose its colour, logo, or shape over time, making it less attractive or uncomfortable to wear. Many stated that gloves are disposed of at a very high frequency.

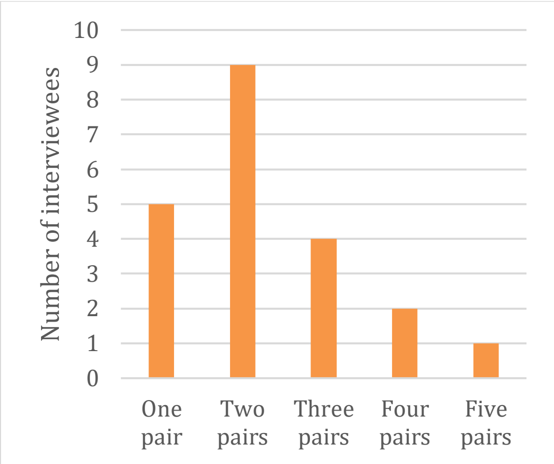

**Figure 1. Number of discarded trousers per year.**

Two opposing forces have affected how often clothes get discarded in the workwear industry in recent years. On the one hand, the design of clothing in the last 15 years has contributed to increasing its lifetime. Fabrics with stretch properties, better fitting clothes, crotch gussets i.e., a diamond-shaped piece of fabric sewn into the crotch area, better reinforcement in the knees and materials that are easier to wash have all contributed to prolonging the lifetime of the clothes.

On the other hand, many said that both construction companies as well as individuals are more concerned about their appearance than they used to be. Appearance is part of a company's branding, and it is also a question of personal image on the individual level.

Therefore, new and fresh-looking garments are considered important. As one interviewee said: "Some people change clothes just because they are done with a construction project". However, this attitude is not true of everyone as a number of interviewees stated that workwear is used until it is worn out and it can image consciousness can mean that some people take more care of their workwear.

### *Washing workwear*

Out of the 25 interviewees, 68% and 16% report washing their workwear at home or on the company's premises respectively. While washing at home is not a problem for most workers, removing concrete and paint stains proves to be a challenge. Additionally, two workers report damaging their washing machines due to forgotten nails and screws in their pockets. T-shirts are consistently washed after every use, but the frequency of washing trousers varies greatly. 20% of workers wash their trousers once a week, 20% every other week, 20% once a month or longer, and 12% somewhat unexpectedly never wash their trousers and 28% are unsure how often they do. With regards to procuring washing services, most interviewees represented small to medium-sized companies that operate at various building sites and therefore didn't view it as a possibility due to logistics challenges. Moreover, construction workers have clothes which fit their size in both length and width, as well as the type of work they do and thus a washing solution with shared clothes, similar to the healthcare sector, is not considered an option.

### *Circular strategies*

None of the interviewees carry out repairs to their workwear. Many expressed that it is not worth their time or effort to repair their garments, instead opting to discard them when they become too damaged. Both repairing them themselves and using repair services e.g., tailor is considered time consuming. Moreover, there are no formal and easy-to-use processes for using repair services. There is also a lack of incentives as it is the company's job to provide new workwear and they personally gain nothing by repairing. One worker said *"if the holes in the workwear become too numerous, it is simply time to dispose of the garment"*.

Workwear cannot be reused by others due to the existence of company logos on the clothes. However, there is potential for reusing the same clothes within the company for seasonal staff, if they are the right size, for the right application and in a good enough condition. Clothes are discarded by the individuals who decide themselves whether to sort them into textile recycling bins or household waste.

## Circular strategies to prolong the lifetime of workwear

Circular strategies describe how companies can go about prolonging the lifetime of a product. In this section we provide an overview of possible circular strategies for workwear based on the results of both sets of interviews. The findings are analysed using the framework of circular strategies presented by Potting et al. (2017).

*Refuse* means abandoning the function of workwear. Workwear is necessary because people need to be clothed and construction workwear fulfils an important safety function. According to the interviews with the construction companies design has already increased the workwear's lifetime and Company 1 said that there is potential for more design improvements. The interviews also revealed that some few workers are replacing clothes due to a desire for new rather than damage, a behaviour which can be targeted.

*Rethink* means that workwear is used more intensively e.g., through sharing. Workers need their specific clothes on a daily basis and there is no time to wash between shifts thus sharing is not an option for this industry. However, Company 1 and one of the interviewees from the construction companies mentioned that through better inventory management seasonal and short-term staff could share clothes. Company 2, similarly, said that some companies have back-up clothes that never get used and could be managed differently.

*Reduce* means increasing efficiency during the manufacturing and use phases. Companies 1, 2, 4, 5 said that manufacturers implement ambitious efficiency measures in production, but that reducing quality will have an adverse effect on the lifetime. According to Companies 2, 4 and 5 there is a potential to increase efficiency during washing by using professional wash services. However, there is a trade-off between the energy saved in the washing and the energy needed to transport the clothes back and forth.

*Reuse* means using discarded workwear, by another worker without intervention to the clothes. Firstly, the consumption patterns show that most of the workwear is discarded when it is damaged thus reuse is not possible. Moreover, the Swedish tax agency states that workwear has to bear the employer's name or logo, so it noticeably differs from ordinary garments if it is to be tax deductible. To make clothes usable by people outside of the company, they should either be re-designed so that the logo is removable e.g., stitched on or the regulations would need to be removed (Companies 1 and 2).

*Repair* means using workwear with its original function, by the same or another construction worker, after its repair and or maintenance. Firstly, repair must not compromise workwear safety (Companies 4 and 5). Nevertheless, physical defects to the product are, according to the construction companies, the most common reason for discarding workwear. Therefore, repair holds a large potential for prolonging the lifetime and is a relatively simple solution that Companies 2, 3, 4 and 5 are implementing. However, Companies 3 and 4 said that workwear is still relatively cheap, and labour costs for repair and freight are expensive, making repair only marginally cheaper that buying new. These costs could be lowered by sending workwear in bulk for repair. Similarly, to the construction companies, Company 4 said that incentives were missing for workers to repair and suggested lowering their allowance for buying new clothes. Both Companies 4 and 1 said that the workers need a simple and well-organized process for sending and receiving garments and paying so as to make repair more convenient. The interview study also revealed that 12% do not wash their work trousers and 20% do it once a month s, and thus, washing could potentially prolong workwear lifetime. Moreover, wash contracts usually include repair. Wash contracts is a strategy that Companies 2, 4 and 5 implement although they are in complete agreement with the construction companies, that it is not currently suited to small companies that move around different construction sites. Moreover, Company 2 who is experienced in this sector said that the environmental benefits are uncertain due to impacts from digitalization, transport and the amount of clothing needed per person.

*Refurbish and Remanufacture* means to restore workwear to its original function by making quite large interventions or by only using parts of it. This strategy was not mentioned by any interviewee, probably because the properties of workwear do not allow for larger interventions beyond repair. Company 1 however has designed modular clothes where the knees which wear out fast can be replaced by the user. The aim is to sell this as an on-demand refurbish option. This demonstrates that design might make this strategy possible.

## Conclusions

This research presents data on the consumption patterns of construction workwear and explores the potential of various circular strategies to prolong construction workwear's lifetime. The main findings are that construction workwear is discarded because it loses its functional properties e.g., damage but also because it loses its aesthetic and comfort properties. Most workers wash their clothes at home but 20% wash their trousers once a month or more seldom and 12% never wash them. The effects of this are unknown but could potentially shorten the lifespan.

The most promising circular strategy for construction workwear is repair although construction companies need to set up easy-to-use processes and incentivize workers to send clothes to repair. Improving quality through design to extend the lifespan is also promising. Design plays a key role in enabling many circular strategies for workwear e.g., refurbishing. Some strategies might need government support such as putting a stop to some fast fashion tendencies that have been observed before they become commonplace and changing regulation about company branding of workwear to allow for reuse.

Similarly to Kumar et al. (2022) and Malinverno et al. (2023) this study also finds that workwear offers a different set of opportunities in terms of circular strategies compared to fashion because, for example, it is a B2B transaction so freight costs for repair can be minimized. This study goes a step further and shows that the workwear industry cannot be considered a homogeneous market, because different conditions that influence circular strategies apply to different segments. For example, rental contracts that include wash services and sharing of clothes between staff commonly used in the healthcare sector cannot be easily transferred to the construction industry where construction workers move around various construction sites and need clothes that fit their size and job. Therefore, the workwear industry should be both differentiated from the fashion industry and further segmented when exploring circular strategies on a granular level. Further research is needed into the various workwear segments and their contexts.

## Acknowledgements

# Thoughtful: Towards the longevity of wooden buildings for climate change mitigation and adaptation

**Kantele, Saara[a], Hughes, Mark[b]**

a) Studio Kantele, Helsinki, Finland
b) Aalto University, Espoo, Finland

**Keywords**: Forests; Wood construction; Building life cycle; Demolition; Building obsolescence.

**Abstract**: The building sector is no longer functional; if we wish to maintain a livable planet a major shift in mindset and practice is urgently needed. Wood construction has been identified as an important way to decarbonise the built environment. However, sourcing wood *must* consider *all* the values of the forests; so to avoid overharvesting, biodiversity loss and other damage to ecosystem services, we should use wood thoughtfully. New wood buildings should be designed for adaptation and disassembly and built to last, and the lives of old ones should be extended. Currently, little is known about the factors affecting the lifetime of wooden buildings and holistic comprehension is needed to support the transition towards long-lived and resilient building stock. In this paper we aim to better understand the lifespan of wooden building, the key factors affecting it, and propose means to extend the building lives; this can also support and promote new, durable, wood construction. Using a combination of literature study and semi-structured interviews, we explore factors affecting the longevity of wooden buildings and the reasons for major renovation or demolition. We adopt a process approach that takes the different events in the life cycle of a wooden building as the primary units of analysis and map the underlying reasons affecting building longevity within these units. Preliminary results suggest that the lifespan and sustainability of wooden buildings is a multi-layered complex matter that is already affected long before the actual building process starts, with forestry choices, planning, cultural aspects, investment, and legislation having an impact; and after the start of the building process by design, craftmanship and material choices, local attitudes, the understanding and knowledge of wood buildings and their aesthetics, as well as geopolitical trends, maintenance and renovation.

## Introduction

Accounting for over a third of final energy use and nearly 40% of global $CO_2$ emissions (UN Environment Programme, 2020), the building sector is also responsible for around half of the 100 billion tons of raw materials extracted annually by humankind (Circle Economy, 2020; European Commission, 2004). Moreover, construction and demolition waste accounts for almost half of the total annual wastes in the EU (Eurostat, 2018). With an increasing urban global population needing good-quality dwellings, the demand for buildings is unlikely to diminish; yet if we continue to construct in the way that we do, 35–60% of the remaining carbon budget will be consumed by 2050, even if we are to limit climate heating to 2 ºC (Müller et al., 2013). Clearly, the building sector is no longer functional if we are to keep the planet liveable, and a major shift in both mindset and practices is needed. Change is at hand, so we need to ensure that this transition does not create new problems, and for this we require a holistic understanding of the whole building process.

Wood construction has been proposed as a means of facilitating this transition and it has been suggested that the widespread adoption of engineered wood in multi-story buildings could make the sector a carbon sink (Churkina et al 2021). Wood-based products store carbon and substitute functionally equivalent materials (Leskinen et al., 2018). The sequestered carbon stored in wood is only released back to the atmosphere when it is burned or decays, so long-lived wood building products are effective carbon stores.

Why not simply increase the amount of wood construction? Mishra et al (2022) recognized that to increase global wood construction to the level required, the harvesting of unprotected natural forest and an increase in tree plantations would be needed. In Europe, another study concluded that should wide-scale wood construction be adopted, the net effect on the sink capacity of the forest-harvested wood products sector would be negative (Jonsson et al, 2021) and in an open letter, a group of Finnish researchers stated that increasing the harvesting and use of wood in line with the bioeconomy strategy would decrease biodiversity and accelerate climate change (Researchers' Statement, 2017). Worryingly, these predictions appear to be coming true, since the Finnish land use sector became a source of emissions in 2021, partly because of over harvesting (Official Statistics of Finland, 2022).

To reduce the ever-increasing pressure on forests, we should use wood more thoughtfully and sparingly by extracting as much utility as possible from existing wood products. From a circular economy hierarchy perspective, reducing the consumption of resources, by extending the lifetimes of buildings and the materials that they contain, is preferable to recycling building products after demolition. This also has clear implications for climate change mitigation since, in terms of carbon storage, extending building lifetimes is more beneficial than recycling the wood products they contain (Hill et al. 2020).

Whilst the average lifespan of buildings in Finland is known, the factors affecting this are less well understood. Moreover, holistic knowledge of the means and capacity of extending the longevity of the buildings is insufficient. The aim of the ongoing study reported in this paper is, therefore, to generate a better understanding of, and new knowledge about, the lifespan of wood buildings and to propose ways in which their longevity can be extended. Moreover, this can support and promote new, durable, wood construction. These actions will help extend the carbon storage of wood-based building products, reduce the need for primary resources, and so help mitigate climate change. We report preliminary results from this study.

## Methodology

To investigate the factors that affect both the longevity of wooden buildings and the reasons for their demolition, we utilised a qualitative approach comprising desk research tasks and interviews, collecting data through a literature search and semi-structured interviews with relevant actors. A snowballing approach was used to identify additional interviewees from the initial interviews. Interviews are still ongoing and have included discussion with experts and researchers from the following disciplines: Forest management and politics, forest bioeconomy, legislation, business and society, building economics, wood architecture, vernacular architecture, wood construction, wood science and technology, indoor air quality, and building inspection and conservation. Additionally, participatory observation in events, seminars and meetings was used to complement our understanding.
To undertake the analysis, we adopted a process approach, shown schematically in Fig.1, that creates analytical constructs from the different events in the lifetime of a wooden building as the primary units of analysis, and maps the underlying factors affecting building longevity within these units. The phases included in the process are Forests, Circumstances, Preparatory, Design, Construction, Maintenance and Beyond. This approach was complemented using an iterative research process and systems thinking to ensure a holistic viewpoint.

## Results and discussion

The results suggest that factors relevant to the longevity of wooden buildings can be broadly divided into two categories; The first comprises factors that are relevant before the building process begins and the second are factors that are relevant after the start of the building process. The first category includes phases 1-3 in Fig. 1 (*Forests, Circumstances & Preparatory*) and the second, phases 4-7 (*Design, Construction, Maintenance,* and *Beyond*).

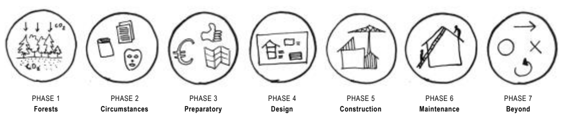

**Figure 1. The phases of the wood building process that are being investigated.**

## Phases 1-3: Before the building process begins

Throughout all phases, it seems crucial to change the mindset and alter the emphasis of the wood building process. Currently, wood buildings are mainly thought of as 'temporary' (albeit some decades), whereas we could consider them to be 'practically permanent' (some centuries) or, in some cases temporary with the permanent use of the material through cascading supported by e.g., design for disassembly. We should plan and understand the life span of the buildings accordingly.

### *Phase 1: Forests – global resilience and the origin of materials*

From our interviews and background research, clearly wood should be used for buildings to help mitigate climate change (e.g., Churkina et al 2020) and reduce resource extraction, yet at the same time, forests should be preserved for the resilience of the planet. To achieve this, we should make efficient use of the wood extracted from the forest, and the wood that is harvested should be directed towards longer-lasting, higher-value products. This finding is not new; EASAC (2017), for instance, stated that since "*using wood in durable commodities and construction allows carbon to be stored over long periods, these uses should be stimulated*". Forestry practices should be developed; accordingly, longer rotations and more continuous cover, with focus on quality.

Finland has a growing domestic market for wood building and so the emphasis on wood production should be shifted towards quality rather than quantity. By harvesting less and creating more value from what we take from the forests, we could generate new employment in the more labour-intensive wood building products sector. This has economic potential and may favourably influence the future know-how of Finland.

Our findings suggest that a shift in the product line is the first part of the change, and the second is the efficient, holistic use of the materials harvested. By using the whole tree and side streams more efficiently and directing them to higher value products, ensuring the longevity and maintainability of these 'products' and cascading the material multiple times, we can reduce the pressure on primary resources and create a healthier wood life cycle chain. This will also help maintain a livable planet by protecting the forest carbon store, most of which is in the ground (Pan et al, 2011), maintaining active carbon sinks now, when we most need them, and help recover and save the remaining biodiversity. All this contributes to resilience of the forests and the planetary system.

### *Phase 2: Circumstances – cultural and legislation impact*

Legislation and policy guidelines appear to have a significant impact on the longevity of buildings. Additionally, attitudes and cultural aspects, like habits and customs, seem to have an influence.

Both in the EU and at national level there are strong incentives to prolong building lives in connection with sustainable building practices, the green transition and climate change mitigation. Laws and guidelines have already addressed this issue, and both the EU circular economy strategies (European Commission 2020) and the Finnish Building Act 2023 (YmVM 27/2022) address building durability and longevity. Within the legislation some of the main factors having an influence are: supporting the different roles of the forest and material use, supporting adaptability and resilience within the city structure, setting and supervising goals for longevity, and requiring reasoning and possible compensation for demolition.

Whilst wood has long been the main building material for detached houses (Nasiri et al. 2021), attitudes towards constructing apartment blocks and public buildings from wood have changed and are now more positive. Circumstances also seem to now be more positive towards continuous cover forestry that could emphasise quality over quantity and the production of building scale wood instead of smaller scale wood for fibre. Nevertheless, there also seems to be doubt about using wood for new purposes e.g., wood building, because of threats related to the forest carbon store, carbon sink and biodiversity – issues that would need to be tackled to ease this doubt.

Existing habits and practices seem to hinder changes to building practices.

*Phase 3: Preparatory – influence of building decisions*

Considering preparing for building, urban planning and building economics are the two main factors investigated so far. The green transition connects both these categories, and it seems that a clear economic plan to transition to a carbon neutral society is needed.

It has been noted by interviewees that urban planning as well as the city structure and density can affect obsolescence and, moreover, flexibility i.e., the adaptability of the buildings and spatial functions, can affect the decision to demolish or not.

Regarding building economics, it seems that key issues affecting longevity include redundancy – the need for the building, the profit motive, e.g., constructing more floor area on a given plot, spatial obsolescence, and perceived risks. These issues were raised by several interviewees and seemed to apply irrespective of the building material, and be closely connected to political decisions, the location of the building, and banking practices. Wood buildings are still perceived to be more expensive, although it seems that they can command a small premium due to demand. Insurance costs do not seem to have a significant influence. Further, the share of renovation practices in the building market is growing (37% in 2021), whilst the share of new building is decreasing (45% in 2021), renovation having larger housing share in housing in 2021. The RT (The Finnish Building Industry) estimates that to achieve green transition, a huge possibility for the country according to them, the renovation construction should double. The shift towards renovation and maintenance would contribute directly to the longevity of buildings and is necessary to prolong building lives (RT 2023).

## Phases 4–7: After starting the building process

In general, it seems that we need to start to design and build permanence or 'thoughtful temporality', with repurposing of building materials in mind. We should emphasise design and building for resilience, adaptability, and a changing climate, preparing for unexpected situations, extreme conditions, and increased moisture, or heat related issues (Lü et al., 2018). For this, according to a number of interviewees, more specialised professionals, greater knowledge and expertise and more examples of resilient wooden buildings are needed.

*Phase 4: Design – contemplating impact*

The design mindset and design decisions affect longevity. When designing for permanence, all structures should be easy to maintain and designs should be resilient considering unanticipated faults, some of which will eventually arise. The structures and maintenance of the building should also be understandable for users, with simplicity and accessibility of the structure being one means to achieve this. Moreover, known risks to structures should be avoided, by e.g., ensuring that they can dry readily, and that future risks, such as coping with changing weather conditions, are carefully considered.

To avoid obsolescence design for flexibility, repurposing, disassembly, and relocation or reuse are important tools.

*Phase 5: Construction – building to last*

The building construction mindset can also affect the permanence of a building or building elements. High quality work and building for ease of maintenance and the replacement of materials, are important. Additionally, it is important to avoid moisture damage at the construction stage. In the worst case, building guidelines or instructions risk hindering the wood building process. As noted earlier, more examples of resilient long-lasting wood construction are needed.

*Phase 6: Maintenance – sustaining the longevity*

By increasing longevity and growing the (wooden) building stock, the role of maintenance and renovation will become more important. All buildings need maintenance, and the focus should be on 'lighter' continual maintenance instead of neglect and major renovations; over-renovating should be avoided. However, some building typologies not well designed for maintenance, may present challenges in maintaining them, and may need larger renovations instead. When renovating, adequate expertise and professionals educated and specialised in wood building maintenance are crucial; a lack of both, according to several interviewees, exists.

Understanding buildings is important to avoid the risk that renovation might even compromise building longevity. In wood building it is important to use materials that are suitable for the building, and to understand e.g., the role of the attic and cellar on airflow in current building structures. According to some interviewees, creating living spaces in these spaces may present risks. Forthcoming energy renovation requirements were regarded by several interviewees to be possible risk factors, both for the structures of wooden buildings, if overdone, and affecting the decision to demolish if it was deemed uneconomic to renovate an older building. Additionally, regular condition examination of buildings is recommended.

### *Phase 7: Beyond – permanence, reuse and demolition choices*

When does a building come to the end of its life? Does it? To promote longevity, we need to see the value in existing buildings and have the motivation to preserve them; to value the historical layers, the time and materials contained in the building. Sometimes *we* also need to adapt to the buildings.

The most important lifetime decision of a building is avoiding uselessness. If the building has no function the motivation to maintain it decreases. Thus, proper maintenance and keeping the building in use, healthy and functional is essential. Understanding the building and its maintenance needs are, therefore, extremely important. Additionally, the adaptability of the building and that of the city plan directly affects building longevity.

## Conclusions

We present the preliminary results of an ongoing investigation into the factors affecting the longevity of wooden buildings. Employing a systemic approach and considering all the phases in the lifetime of a wooden building, we identify some of the main issues that affect this. Well before building construction begins, the quality and availability of the raw material, the legislative and regulatory environment, all have an effect. Design decisions and the current mindset, along with the construction itself, and subsequent maintenance also dictate longevity. Perhaps the biggest question of all is what does building longevity mean? This is a question we aim to address in our future work.

## Acknowledgments

The authors gratefully acknowledge funding from the Finnish Ministry of the Environment under the Low Carbon Built Environment Programme. Our thanks are extended to all the interviewees who have given freely of their time and expertise.

# Ethical Consumption in Sweden and Iran: A Cross-Cultural Analysis

**Sara Karimzadeh[a], Magnus Boström[b]**
a) Marie Curie Research Fellow, Örebro University, 701 82 Örebro, Sweden
b) Professor of Sociology, Örebro University, 701 82 Örebro, Sweden

**Keywords**: Ethical consumption; Social Practice Theory; Sweden; Iran.

**Abstract**:
The act of ethical consumption may take on a multitude of forms, each with its own unique justifications and rationale. This paper aims to contribute knowledge on the various factors that influence ethical consumption, based on a comparison of ethical consumption practices in Sweden and Iran. Using social practice theory and a multilevel approach, our empirical study will shed light on the interplay of various socio-technical regimes such as consumer preferences, norms, markets, technological infrastructures, and policies in the target societies and their effects on the different forms of ethical consumption. We collected data from 34 semi-structured interviews with consumers in both countries. Going beyond micro-level factors, our research indicates that agents and embedded socio-technical regimes play a dynamic role in shaping, constraining, devaluing, or redirecting ethical consumption practices. This study concludes that the idea of ethical consumption as a social phenomenon is constituted within a structure and, in turn, reconstitutes it.

## Introduction

The notion of ethical consumption can be conceived as a set of consumption-related activities that are predicated on the consideration of the living conditions of others. In this definition, the term "others" may encompass individuals within one's own society, such as local labours, retailers and producers, or those residing in other societies. Furthermore, it may also encompass future generations and distinct forms of life, including animals. As consumers become increasingly cognizant of the impact of their consumption habits on "others," the concept of ethical consumption gains greater traction in contemporary society (Lee & Cho, 2019).

In a broad sense, consumption refinement and consumption reduction have been recognized as two forms of ethical consumption (see Li et al, 2020). Consumption refinement involves making conscious choices to purchase products or services that minimize harm to the environment and society (such as buycotting and fairtrade) while refraining from those that do not take social and environmental responsibility into account (such as boycotting). Consumption reduction involves minimizing overall consumption in response to social or environmental concerns. This can involve adopting new lifestyles such as voluntary simplicity, minimalism, and sufficiency.

The extensive literature on ethical consumption has primarily focused on consumption refinement and our understanding of the concept is often limited by two factors. Firstly, this knowledge is primarily derived from Western cultures, which leaves out valuable insights from other regions. Secondly, the understanding of ethical consumption is largely influenced by marketing and socio-psychological approaches, which overlook the significance of social context and its material and non-material characteristics in shaping ethical consumption practices. As a result, the role of meso-level factors in the formation of ethical consumption remains unclear.

The aim of this article is to perform a comparative analysis of ethical consumption between Sweden and Iran. This study seeks to provide insights into the interplay of various socio-technical regimes such as consumer preferences, norms, market, technology, and policy in each society that influence ethical consumption differently.

## Theoretical departure

This study draws upon a synthesis of social practice theory (SPT) and multilevel perspectives in consumption research (as presented in the works of el Bilali, 2019; Hargreaves et al., 2013; Karimzadeh & Boström, 2022; Keller et al., 2022, Gram-Hanssan, 2021). To analyze ethical consumption practices, we adopt an "element-based" analytical framework derived from the work of Pantzar and Shove (2010). Following this point of view, we suggest that every form of ethical consumption, from the established forms such as fairtrade, boycotting and buycotting to more innovative ones that are invented by consumers within the specific social regimes, carries on the elements of conventional practices including *material*, *competences* and *meaning*. That is, ethical consumption will be framed in relation to the existence of elements of practice and the way in which they interconnect. Collectively, these elements constitute the framework of ethical consumption, and their interconnectivity is integral to its function.

## Methodology

This paper uses qualitative methodology. The data was generated through both digital and face-to-face interviews with participants who were asked to reflect on their daily consumption decisions and share their perspectives on how cultural norms, regulations, infrastructures, and technology in their respective countries influence their consumption practices. A total of 34 interviews (15 in Sweden and 19 in Iran) were carried out, involving participants with ages ranging from 18 to 75 years old. In the case of Swedish participants, the interviews were conducted in both English and Swedish, whereas for Iranian participants, the interviews were conducted in Persian.

## Findings

Data analysis indicates that although participants from Sweden and Iran have relatively similar perceptions on subjects such as overconsumption and its negative impacts on nature; the necessity of making changes in current consumption practices; and the prevalence of inefficient policies and regulations to address environmental challenges in their countries, there are nevertheless significant differences among them. These differences originate from contextual, structural, and cultural positions in which they are engaged in their respective countries. This is in line with previous reports that people from different nations and cultures perceive ethics differently and that it impacts their ethical consumption forms (see Bucic et al., 2012).

In Iran, ethical considerations regarding consumption prioritize individual-oriented and locally-based issues that are rooted in human interactions, rather than environmental-related concerns. However, in Sweden, ethical consumption is commonly associated with a range of practices that prioritize environmental sustainability and social responsibility. Nevertheless, with the prevalence of excessive consumption in this country, as highlighted by Boström (2022), it is worth questioning whether Swedish consumers truly engage in ethical consumption or if the definition of ethical consumption requires re-evaluation. Based on our analytical framework, we will explore the development of ethical consumption in the two countries by examining three key components: *material, competence*, and *meaning*.

### *Material: having access vs. not having access*

By *material*, we mean things encompassing tools, infrastructure and objects (Shove & Pantzar, 2005) – including trustworthy information about these materials – which enable consumers to choose “ethically produced goods” or enable them to perceive themselves as “ethical consumers”.

Easy access to recycling facilities, eco-labelled, organic and fairtrade products as well as information about carbon footprints and working conditions in companies, products and production processes are some examples that assist consumers in Sweden to make purchasing decisions with relatively open eyes compare to Iranian consumers.

Living condition in Sweden in comparison to Iran provides a range of larger material infrastructures (such as easy access to eco-labelled, organic and fairtrade products) and non-material amenities (such as having access to information about carbon footprints of products, origin and composition of products and working conditions in companies) for consumers to assist them in their consumption-related decisions. This situation provides a more conducive environment for the development of ethical consumption in Sweden compared to Iran.

For instance, regarding the market for fair trade products in Sweden, one participant said that 20 years ago, he and a group of friends had a plan to encourage local shops to provide fair trade products. He described this effort as successful, due to the support they received from the procurement system at that time. As a result, it helped to develop this behaviour as a norm among others as well. In his opinion, the current situation has made it very easy for people to choose products consciously for two reasons: the availability of materials and having trust in the information cycle.

On the contrary, with limited access to material, which in this case is not having proper access to "ethically produced" products in the market, Iranian consumers are already deprived of the right and opportunity to decide on their purchasing of products within an ethical frame. It can be inferred that sociotechnical regimes encompassing the supply process and market can either impede individuals from actualizing their consumption-related considerations, as observed in Iran, or enable them, as exemplified by Sweden.

### *Competence: do I know what should I need to know?*

The other element of practice is *competence* which represents specific skills associated with specific practice (Warde, 2005) as well as practical knowledgeability (Shove et al., 2012). Although possessing competence on a subject and having a passion for social and environmental issues can encourage consumers to apply their knowledge in their actions (Papaoikonomou et al., 2016), this process is not always straightforward. According to our analysis, there are numerous challenges that can hinder individuals from utilizing their skills, including lack of resources (i.e., know-how, affordability) in their personal lives and restrictive social norms.

Despite the environmental sustainability challenges in their country, Swedish individuals have identified various opportunities within their social structures/system that enable them to engage in "ethical consumption" practices. One Swedish participant mentioned: *"… I think in Sweden, you are like almost brainwashed from when you're born… think about the environment in the kindergarten, in preschool where I worked there… they talk about [the environment] all the time, environment and environment. almost all preschools in Sweden, you get to learn what they [labels] are, what they mean if you have them…".*

Similarly, Iranian participants described their competence in relation to their living conditions and social structure as well. One man told: *"…you like to be committed to your [consumption] responsibility but for how long you can insist on it when others don't feel any responsibility?... also you can be a responsible consumer as long as you have a stable living condition. Otherwise, it is very fragile.*

Therefore, in the context of ethical consumption, competence functions as a part of living conditions, including access to formal education, affordability, and collective action.

### *Meaning: does it make sense or not?*

*Meaning* refers to the "social and symbolic significance of participation" in any practice (Shove, et al., 2012: 23), and includes motivational knowledge, emotions and mental activities (Ibid), as well as shared understanding among a group of people (Pantzar & Shove, 2010). Participants from both countries were critical of the negative consequences of unsustainable consumption in their countries. For Iranians, it was associated with broad social inequality and unfair resource distribution in their country. Participants from Sweden rather highlighted the environmental impacts of overconsumption. Nevertheless, concerning the *meaning*, significant differences can be distinguished between participants from the two countries. Adopting new forms of consumption, buying second-hand products and separating household waste are three topics that have varying implications for individuals from the two countries.

The Iranian participants were primarily concerned with maintaining "balance" when it comes to consumption. Culturally, they believe as long as humans lead a life that is balanced with personal needs, other humans and nature as well, neither nature nor society would be harmed. One Iranian woman told: "… we *can eat meat; we can enjoy life by keeping balance. There is no need to be a completely vegetarian* *or carnivore. We can have both. But everyone should concern that keeping balance is important…*". This idea puts forth a notion of "ethics" that goes beyond simple ethical consumerism. In this culture, leading a life that is harmonious both individually and socially is considered to be a hallmark of someone who does not cause harm to other beings in any way. The Iranian participants believed that maintaining balance in the use of any form of resources was more meaningful than simply abstaining from them. This concept recalls the concept of "sufficiency" in the literature of consumption.

regarding buying second-hand stuff which is a more common culture in Sweden compared to Iran, Swedish participants described it as a fun market, entertaining and exciting whereas economic as well. One Swedish participant indicated that for me, second-hand is "… *the first option to look for, and then if I can't find what I want then I'll buy from like normal store…*". Iranian participants, however, for several reasons, indicated a strong reluctance to purchase second-hand goods whereas mending clothes or repairing broken stuff is more common among them. Inhibitors of having second-hand stuff in Iran are mainly related to the psycho-sociological [negative] loads that seeking second-hand stuff carries in that culture, particularly in clothing.

The other main difference in relation to *meaning* concerns domestic waste separation. Almost all Participants from Sweden admitted that they are engaged in this practice. They find it like a routine practice. Although some of them have no serious pro-environmental motivation in doing so, they do it out of habit. They describe it as an easy practice and good for the environment and indicated a high level of reliance on their waste management system (*material* element). However, Iranian participants do differently. For a few of them, it is not a concern at all. The below quote from an Iranian man represents a common pattern among participants: "… *no, I don't recycle. No. I have never done it before… even if we separate our trash, what happens to them?... there is no proper mechanism for the rest of the work".*

Our research reveals that the perceived meaning attached to practice opens or blocks the way of doing. Waste separation doesn't make sense to many Iranians because they believe that their actions won't fulfill their purpose due to the lack of waste management. That is, the lack of practical intelligibility (Schatzki, 2001) behind "ethical consumption" practices, hinders Iranian consumers to engage themselves in such practices.

## Discussion

Our study indicates that the presence or the absence of ethically-oriented practices among consumers can be to a significant extent determined by the gradual institutionalization of practice elements. Factors such as having access to *materials* – seen as trustworthy - (i.e. market and labelling); having knowledge and skills to be able to employ the material (*competence*); and being fed by social or individual motivations, justifications and understanding in doing such practices (*meaning*) can be crucial to further develop ethical consumption.

Components of practice (*materials*, *meanings* and *competencies)* are created within complex systems of inputs and outputs among consumers (micro level), market, policy, science, technology and industry (meso level) and wider processes of culture and globalization (macro level) that (re)form the entity of society. Practices are constituted by associated socio-technical regimes and performances of practices, in turn, (re)produce and sustain socio-technical regimes (Watson, 2012). The mutual interactions of these systems and their elements create space for the generation of novel practices and socio-technical changes.

Consequently, ethical consumption is more likely to be embraced by a larger group of people in a society when the elements of practice (*material*, *competence* and *meaning*) are constructed systematically and, more importantly, are synchronized. This situation will pave the path of ethical consumption. Otherwise, ethical consumption comes about as an individual discrete action.

We argue that (innovative) consumption practices proceed with lower tensions and fractions when they are granted a level of systemic support like what is happening in Sweden, in the context of ethical consumption, compared to Iran, and has been historically evolved since decades back. Activities like recycling, buying fairtrade and second-hand stuff, biking and so on for Swedes appear like the routine accomplishment of normal ways of life (Shove et al., 2012) and also create a coherent sense of self (Warde, 2005). However, consumers are not simply passive carriers of ethical consumption practices. Instead, they are actively engaged and adept at fostering ethical consumption. In this dynamic process, the accumulation of different performances recreates ethical consumption over time and across space (Hargreaves, 2011; Karimzadeh & Boström, 2022; Watson, 2012).

## Conclusion

According to our study, it can be argued that "ethical consumption', as defined, is more systematically developed in Sweden than in Iran because, in Sweden, the practice can be accomplished through the synergy of agency and structure. This is when new *meaning*s are ascribed to consumption patterns (e.g., arguments such as our consumption shouldn't endanger the lives of others), and creates new demands which bring along new *materials (e.g.* availability of fair-trade products, organic products, local products or systems of waste management) it is followed by new *skills/competencies* (e.g. knowing labels and their meaning, knowing how to repair or share goods) to take advantages such materials. This process enables the refinement of consumption in various forms, creating opportunities for ethical consumption. Our findings suggest that while ethical consumption through consumption refinement is more prevalent in Sweden than in Iran, further research is needed to understand the role of consumption reduction as a form of ethical consumption in Sweden.

# Teaching Fashion Design for Multiple Lives and Users

**Noorin Khamisani**
University of Portsmouth, Portsmouth, United Kingdom

**Keywords**: Circular fashion; Multiple lives; Fashion education; Design education.

**Abstract**: The fashion industry has increasingly come under scrutiny for its contribution to global environmental issues through unsustainable business practices. To address this, a shift towards circular economy principles in fashion design education has gained traction. However, implementing such principles requires research-informed teaching and alternative design processes that challenge the status quo. This research paper presents a project that explores the potential of a design process for garments with multiple lives, informed by circular thinking, as a starting point for fashion design students. This exploratory research project asks: How can design educators incorporate circular economy principles in their teaching by leveraging insights from student perspectives?

Adopting a new design process focussed on multiple lives and users for fashion, situated the students, the class and thus the research in a circular fashion paradigm. Within my own research practice, I had explored adaptability, modularity, and reversible garments. The students expanded the design process, exploring in myriad ways, including garments designed for sharing between genders and ages and modular adaptable propositions. Some students went even further and began mapping their own alternative design processes, utilising 3D printing and biomaterials combined with laser cutting and upcycling. There is significant potential for evolving and applying a multiple lives design process linked to circular fashion practice within design education. Students were inspired by the boundaries set and responded with creative and innovative outcomes which in turn can teach and develop educators. Furthermore, their ideas could be valuable to transforming the fashion industry, as they suggest alternative sustainable fashion systems for the future.

## Introduction

The fashion industry has increasingly come under scrutiny for its contribution to global environmental issues through unsustainable business practices (Niinimäki et al., 2020, 189). To address this, a shift towards circular economy principles in fashion design education has gained traction. However, implementing such principles requires research-informed teaching and alternative design processes that challenge the status quo. This paper presents a project that explores the potential of a design process for garments with multiple lives (Khamisani, 2021, 351), informed by circular thinking, as a starting point for fashion design students. Drawing on my previous research and personal practice, the project aims to offer a critical reflection and alternative approach to the dominant cradle-to-grave fashion model (McDonough & Braungart, 2009). As Escobar points out, the contemporary world is experiencing a design failure (Escobar, 2018), and the fast-fashion system has a detrimental impact on both people and the planet. The multiple lives design process aims to challenge this by emphasising longer lifecycles, multiple users and alternative business models such as rental or product as service (Lacy & Rutqvist, 2015). The project was implemented in a third-year module at a new interdisciplinary design university in the United Arab Emirates (UAE) between 2020 and 2021, and this paper presents the insights gained from that experience.

## Circularity in fashion practice and education

The adoption of the Circular Economy (CE) and/or Circular Design (CD) within fashion has its supporters and its critics. Brands such as Louis Vuitton, Gucci, Patagonia, and Levi's are increasingly making claims with regards to their CD ambitions. The Circular Fashion Index report measures the efforts of brands to extend the use phase or lifecycle of clothing to reduce their environmental impact (Kearney, 2022). Although theoretically CD or CE should generate a move towards sustainability, Greenpeace has reported this is not always the case (Greenpeace International, 2017). In fact, a great deal of CE within fashion is simply focussed on recycling rather than avoiding the creation of waste in the first place.

When exploring circularity in fashion broadly, research indicates that there is a gap between what is being taught in educational establishments and what is required in industry (Østergaard & Dan, 2021, 1). Many designers find themselves faced with challenges they were not taught to consider in their training. There are some movements to change this and a good example of closer collaboration between industry and education is the Circular Design Guidebook produced by ASOS and The Centre for Sustainable Fashion based at UAL London College of Fashion. The Guidebook is aimed at both fashion designers and students and is focussed on material choices, design strategies and recycling (2021). Furthermore, many universities internationally are engaging with CE through their teaching and research (Ellen MacArthur Foundation). Embedding CE in education and training fashion students in CD is important, but this will only be impactful in the long term if coupled with systemic interventions in business across the fashion industry (Østergaard & Dan, 2021, 4). Earth Logic takes this notion even further by highlighting that "there are a pluriverse of possible fashion systems if we set fashion free" of industry conventions (Fletcher, & Tham, 2019).

## Circularity as researched-informed teaching

A common misconception among educators is that innovation in pedagogy is too time consuming and therefore a student-centred and/or a research-informed approach is not always adopted (Jessop & Wu, 2017, 1155). In the context of a newly established university, we had no choice but to innovate as we collaborated with US institutions on the original curricula which needed to be locally contextualised in the UAE. The fashion curriculum came with learning objectives that embraced sustainability, which I then developed to include aligned modules and project briefs.

In my research on Fashion Design for Multiple Lives, I had reflected on my own training and the importance of applying that to my pedagogy (Khamisani, 2021). Fashion designers are normally trained to design for a single user in a linear system, whereas with CD we consider multiple lifecycles and users. Within my research I had considered adjustable sizes, adaptability, modularity, and reversible garments. By bringing my multiple lives design process into my teaching I was able to give my students the opportunity to build and expand on these possibilities. This in turn could highlight approaches or perspectives I may not have considered in my research and pedagogy previously. This exploratory research project asks: How can design educators incorporate circular economy principles in their teaching by leveraging insights from student perspectives?

## Methodology

The paper utilises a mixed methodology (Creswell, 2014, 203) and draws on qualitative data which includes: student project outcomes, their reflections, and a thematic analysis of my own reflections as an educator. To fully address the research question, it was essential to consider the perspectives of the students as well as the educator.

Adopting a new design process focussed on multiple lives and users for fashion, situated the students, the class and thus the research in a circular fashion paradigm (Scotland, 2012, 9). Furthermore, this research was situated within a critical paradigm, in that the brief aimed to propose how the fashion industry ought to be, which positioned it as a critique of the current dominant fast fashion system. Students worked in groups of two or three as mini design teams to mimic what is done in industry and to encourage collaborative learning. This added a further dimension to critique the notion of the lone star designer which is also in need of change (Edelkoort, 2015). The students were also required to consider how they could incorporate their own design of materials into one physically produced jacket and an illustrated collection of six outfits. The module was run three times, with each iteration pushing the next one forward in terms of results.

*Positionality*
I am a mixed-race academic, educated in the UK, this research was conducted while I was living and working in the UAE, where I endeavoured to teach with a decolonial approach, embracing fashion as a global rather than Euro-American phenomenon (Welters & Lillethun, 2018, 2). I acknowledged the links between colonialism and an unsustainable fashion industry through my course content. Nevertheless, my worldview may have affected my analysis of student work and my reflections within this project (Patten & Newhart, 2018, 163).

## Results and discussion
The project challenged fashion students to think about multiple lifecycles for their designs at the outset, to inform their decisions in terms of materials, silhouettes, and users. A total of fifteen collaborative design projects were created. Due to the qualitative nature of the data, I will present the results and discussion together, broadly following the key themes of the approaches to multiple lives evidenced by the students.

*Multiple lifecycles and users: Sharing between genders and ages*
Within my own research practice, I responded to the multiple lives design process through adaptability, modularity, and reversible garments. The students expanded the design process, exploring in myriad ways, including garments designed for sharing between genders and ages, as well as modular adaptable propositions (where the garment could be worn in different ways). Some students went even further and began mapping their own alternative design processes, utilising 3D printing and biomaterials combined with laser cutting and upcycling.

All the student projects embraced the notion of garments being shared as beneficial to ensure multiple users. This sharing was proposed across various formal and informal situations. I had specifically explored a rental or product as service model in my work. The students were more interested in informal sharing between genders and age groups.

Fashion education and the industry predominantly creates for either women or men. Designers are trained to create for a specific gender and retailers in turn divide their shop floors accordingly. Eight groups out of fifteen specifically aimed to design genderless collections and two aimed for a unisex outcome. Designing beyond gender binaries critiques the current fashion system as well as posing new challenges for educators. Currently mannequins and pattern making blocks are designed for male or female forms, in many ways we were not equipped to deeply explore what designing in this way means. However, the experiences gave both the students and the educator an opportunity to realise how entrenched gender binaries are, and how much work is needed if we are to move beyond them.

Another engaging aspect was the variety of sharing situations the students chose to design for. These included: husbands and wives (2 projects), mothers and daughters (1 project), brothers and sisters (2 projects). These are situations we can imagine occurring, but they are not specifically designed into a garment, rather they are a use phase happy accident. Again, we do not often design for intergenerational sharing, although it offers an engaging provocation. Likewise, for educators this type of multiple use poses a challenge. These myriad users and sharing situations align with the Earth Logic proposal of “a pluriverse of possible fashion systems” (Fletcher, & Tham, 2019).

*Multiple use-phase: Modular designs*
A significant approach to designing for multiple lives, which built on my own research, was the consideration of modular or adaptable garments. This was utilised by eight groups, with others also mentioning accessibility and interchangeability. Each group took slightly different approaches linked to their proposed users, some were simply jackets with elements which were removable or changeable, others designed jackets that could be turned upside down and worn. Going further with modularity, one group proposed a genderless childrenswear jacket, with separate bodice parts which were linked by 3D printed elements so that the length of the jacket body could grow with the child, and a removable hood made from a bioplastic. The design was supported by lifecycle mapping to work through the possibilities (Figure 1). This project was

particularly successful and was showcased at the prestigious Global Grad Show during Dubai Design Week 2021 in the UAE.

*Multiple Materials*
Within my own research, I had looked at materials with qualities that are valuable for longevity, easy wash care and mono-materials (for ease of recycling). The students' approaches to materials for multiple lives were particularly engaging. I stipulated a specific need for their projects to include creating their own materials in any way they felt aligned with their concepts. Every group utilised either 3D printing or biomaterials, with some combining these with laser cutting and upcycling, techniques that are still relatively new within fashion practice.

The incorporation of biomaterials was particularly successful when paired with multiple lifecycle thinking. One group developed an aloe vera biomaterial with 3D printed elements that became a removable accessory of a genderless jacket. This project was selected to be showcased during Dubai Design Week 2021. Another group, creating a collection with a focus on design activism, created a biomaterial which could be zipped on and off a multiple sized genderless jacket. These projects evidence the students' abilities to navigate a complex variety of alternative design considerations alongside material development.

Several students took the ideas they explored in this module further through their independent thesis projects in their final year. One student wrote in their thesis of the impact that sustainable and circular fashion design training had on his approach and went on to develop a completely biodegradable fashion collection with seed-embedded fabrics that began growing. These garments embodied the lifecycle thinking explored through the multiple lives design process.

*Multiple Cultures*
Two student groups identified culture as part of their design considerations, an approach I had not considered within my research on multiple lives. One group decided to redesign a Bisht, a traditional Emirati garment, historically worn by men but more recently, as the garment is passed down through families, women are also wearing them. This project drew on a real-life multiple lives garment and redesigned it to be genderless and modular. Where the Bisht is usually floor length, they created the option to wear it as a mid-length jacket through a section that could be removed. While the original Bisht was designed for longevity, here the students added another level of sustainability.

*Teaching multiple lives*
Teaching fashion design for sustainability can be difficult, with resistance from some students who feel limited or even depressed when faced with the challenge of the climate emergency. I have previously had student feedback where they say they want to learn about “more than sustainability in fashion”. What was valuable in this project is that we utilised a new design process to directly propose potential solutions to the wasteful short and singular life cycle most fashion items are designed for. Therefore, I could see the student outcomes directly respond to the concept of multiple lives and users. Their mindset was positive, and they could actively engage with suggesting alternatives to the current fashion system.

Embedding CE in education and training fashion students in CD is important, but this will only be impactful in the long term if coupled with systemic interventions across the fashion industry (Østergaard & Dan, 2021, 4). Perhaps the value of addressing CD in education will be for more entrepreneurial graduates, who rather than going into existing businesses, use their training to design new systems for fashion.

As an educator, my most poignant reflection is regarding the overall impact of this work. It was both challenging and exciting to see my own design process interpreted by my students. Their design responses made me think differently about my own design practice as well as offering engaging solutions that could be applied to both industry and education.

In many ways as educators, we are limited by the university's systems and processes that ensure that incremental changes are possible but radical changes are rarely embraced.

In this project, the students and the researcher were collaborators in gaining new knowledge around the practicalities of working with new and varied CD processes. The results of the research are both long and short term. In the short term the cohort of students now have experience of designing fashion in a circular paradigm, in the long term we collectively have valuable experiences and examples of student work to draw on to embed changes in the curriculum.

I certainly learnt a lot from this experience and hope to find another opportunity to teach students this design process at other institutions. I would then have more examples of student work which would provide valuable data for further research.

## Conclusions

Research informed teaching has many benefits including improving students' learning, subject knowledge, and confidence (Jessop & Wu, 2017, 69); this was evident within the project. Furthermore, there was a benefit to me as an educator.

The student's work in response to the design process for multiple lives and users evidenced a more open and inclusive approach to fashion design, specifically around gender, ownership, and adaptability. If we view this project as creating new knowledge around teaching fashion design, this creates an opportunity to revisit the curriculum and our teaching methods.

As educators we should continue to unlearn our own design training to push teaching and learning away from linear systems and towards successfully integrating the circular economy. This requires a re-evaluation of not only *what we teach* but also *how we teach*. Embracing alternative design processes can also include more fluid roles between the educator and the student. This leads to alternative pedagogies which highlights the fact that everyone has something to teach (Thompsett et al., 2022). In this case the students became the experts in their own alternative design process. This led to engaging thesis work for their final year projects, in which many of them further applied a critical lens to the dominant fashion system.

Overall, we can surmise there is significant potential for evolving and applying a multiple lives design process linked to circular fashion practice within design education. Students were inspired by the boundaries set by CD and responded with creative and innovative outcomes which in turn can teach and develop educators. Furthermore, their ideas could be valuable to transforming the fashion industry, as they suggest alternative sustainable fashion systems for the future.

## Acknowledgments

This research was conducted with the fashion design students at the Dubai Institute of Design and Innovation, and I would like to thank them for their participation and engagement.

# Regulating Fast Fashion out of Fashion

**Ingun Grimstad Klepp[a], Kerli Kant Hvass[b]**
a) Oslo Metropolitan University, Oslo, Norway
b) Aalborg University, Copenhagen, Denmark

**Keywords**: Fast fashion; Clothing use and durability; Textile waste management; Extended Producer Responsibility (EPR); Targeted producer responsibility.

**Abstract**: Among sustainable fashion and textile themes, product durability has recently come into focus within EU policy making. The dominant understanding is that increased textile lifespan will reduce environmental impacts, but this intrinsic link is not supported by research. The volume of clothing produced poses the greatest environmental burdens. Increased clothes availability leads to longer lifespan due to reduced utilization. To reduce the environmental impact of increased textile volumes measures should be expanded to encompass not only product design, life-prolonging, and end-of-life strategies, but also the volume of products to market. This concept paper contributes to the debate on how to address the growing amount of textile waste by applying the knowledge gained from consumer research regarding clothing use and proposing a regulatory measure called Targeted Producer Responsibility (TPR). The central method of TPR is waste analyses which relies on actual use - or non-use - of products as the starting point for eco-modulated fees. TPR reverses EPR and uses waste for overproduction knowledge, thus proposing a tool that can potentially reduce the total environmental impact of textiles.

## Introduction

Attention related to clothing and the environment is gaining momentum worldwide and the EU is at the forefront with its Circular Economy Action Plan and EU Strategy on Sustainable and Circular Textiles (European Commission, 2022). A dominant theme in the EU strategy and relevant literature around "sustainable" and "circular" textiles is increased product durability. There is a widespread view that the increased lifespan of textiles will reduce environmental burdens. This intrinsic link is not supported by research. We stress that to reduce the environmental impact of textiles, measures should be developed that encompass the volume of products produced or imported. The aim of this concept paper is to enrich the debate on how to tackle overproduction, building on the knowledge gained from consumer research on clothing use, and to propose a future policy measure called Targeted Producer Responsibility (TPR) (Klepp et al., 2022b). TPR is a proposal on how Extended Producer Responsibility (EPR) for textiles might reduce fast fashion, over-production and thereby also the environmental footprint of the sector. TPR uses the actual use - or lack of use - of products as the starting point for criteria for EPR fee-modulation, rather than potential lifetime.

## Background

### *Fast fashion and overproduction*

Fast fashion is a business model that relies on cheap manufacturing, frequent consumption and short-lived garment use offering consumers regular novelty in the form of low-priced, trend-led products (Niinimäki et al., 2020). By its very nature, fast fashion encourages overproduction because new products are constantly appearing in stores, making the old ones obsolete. The Oxford Learner's Dictionary (n.d.) defines overproduction as "*the act of producing more of something than is wanted or needed*". This means that the total amount of clothing and other textiles exceeds consumers' actual clothing use and thus represents a surplus of clothing. Surplus clothing are goods that are unsold, returned goods that are not resold, goods that are discarded after purchase or stored unused in consumers' wardrobes. At the same time, FF makes garment repair unnecessary (because garments are discarded before they are damaged), uneconomical (because new garments are very cheap) or impossible (because garments are too flimsy) (Middleton, 2015). In a sales-driven FF business model, product durability is neither a major concern for the consumer nor the manufacturer (Ekström & Salomonson, 2014). Overproduction is also visible as waste export. Recent studies show that the amounts of used textiles exported from the EU have tripled over the last two decades from over 550,000 tonnes in 2000 to 1.7 million tonnes in 2019, and the fate of these exported clothes is highly uncertain (EEA, 2023).

*Consumption of clothing: The relationship between longevity and quantity*

Consumer research that provides information on the use of clothing has not been adequately considered in sustainable textile strategies and policies (Klepp et al., 2023a; Klepp et al., 2023b; Klepp, et al., forthcoming). At the same time, the use phase (wears and years) is crucial for impact per wear (Klepp et al., 2020; Watson & Wiedemann, 2019). Although, the use phase is complex, because the clothes are part of a system where their mutual relationship in wardrobes is decisive for their use.

We see a trend that various policy discussions and documents are based on the belief that making garments more durable with the help of eco-design requirements will reduce the textiles' impact on environment. For example, the EU Textile Strategy says: "*extending the life of textile products is the most effective way of significantly reducing their impact on the climate and the environment*" (EC, 2022. p.3). However, this only applies if there is a clear product replacement, but as Maldini (2019) argues, most clothing is not acquired as a replacement. Acquisition and disposal are connected, but independent processes. The quantity of owned garments plays a main role in this relationship (Maldini & Stappers, 2019). One reason for disposal is the limited space in wardrobes, which is a consequence of purchasing and not its cause (Laitala & Klepp, 2015). This is also the case for second hand, hand-me-downs, home-made garments, and gifted clothes (ibid).

Studies on disposal of clothing show a threefold division between lack of perceived value, bad fit, and wear and tear problems (Laitala & Klepp, 2022). Only a third of the clothes go out of use because they are worn out. The same pattern occurs in textile waste streams (Klepp et al., 2022b). More durable clothes will therefore not affect the disposal of 2/3 of the clothes. For example, in the work with EU's Product Environmental Footprint Category Rules (PEFCR), longevity is mainly understood as strength and thus favours synthetic fibres (Klepp, et al. 2023a). Confusing strength with longevity is a serious misunderstanding because plastic is incredibly durable. Therefore, future policy measures should not only target individual products and their design, for example in the form of stronger products, but also what is characterised by fast fashion, high volumes and, consequently, low utilisation rates for clothing. This will ensure that measures taken to reduce environmental burden of textiles must cover whether clothes are used and not just that they can potentially be used, and that measures must target systems, not just individual products.

*Textile policies and strategies*

The fashion and textile industry remains largely unregulated with respect to social and environmental impacts, which is one of the root causes for the growing negative impacts of textiles throughout the lifecycle (Vase, 2022).
In a recent study (Klepp et al., fortcoming), 11 textile strategy documents from public, private, and non-profit organizations were analysed with regards to whether and how growth and plastification (the synthetic fibre content in textile products) is being addressed. The study shows that several reports include overproduction and the desire to reduce fast fashion. However, this wish is not reflected in the measures proposed in these documents, as the study found no measures nor clearly formulated goals aimed at reducing the amount of manufactured or imported products. The most important themes that were highlighted in connection with growth were not quantities produced, but quality of products and production processes. For example, the EU Textile Strategy recognizes that "*the trends of using garments for ever shorter periods before throwing them away contribute the most to unsustainable patterns of overproduction and overconsumption. Such trends have become known as fast fashion, enticing consumers to keep on buying clothing of inferior quality and lower price, produced rapidly in response to the latest trends*" (EC, 2023, p. 1). It acknowledges

the urgent need to address quantities towards a transition from linear to sustainable circular system, by saying *"Reversing the overproduction and overconsumption of clothing: driving fast fashion out of fashion"* (EC, 2023, p. 8).The above-mentioned analyses of strategy documents by Klepp et al., (forthcoming) show that growth is often discussed as something that needs to be decoupled from the environmental effects. This is in line with previous analyses of the textile multi-stakeholder initiatives by Payne and Mellick (2022) and could be one of the reasons why, despite of intense effort from the fashion industry over the last 15 years to improve sustainability, the environmental impacts keep growing (Lehmann et al., 2019; Palm et al. 2021; Tham, 2008).

*Producer responsibility*

The fashion and textile industry has been largely unregulated when it comes to overproduction, textile waste and end-of-life practices of textiles. Textiles waste has been handled by municipalities or it has been an important revenue source for the charity sector, often by selling good quality clothing on the local markets and the rest is channelled to global low-income markets (Palm et al., 2014; Kant Hvass, 2014).

In the last decade, producers and retailers have started taking proactive steps in engaging with the post-retail phase of their products (Kant Hvass, 2014; Stål & Corvellec, 2018). However, these voluntary industry-driven initiatives remain incremental in addressing the big amounts of used textiles (Kant Hvass, 2014; Kant Hvass & Pedersen, 2019). At the same time, there is no clear evidence that these initiatives, such as take-back, repair or re-commerce, have any direct effect on the amount of clothing produced. At the same time, growing volumes of FF clothing make it difficult for such business models to be profitable.

*Extended producer responsibility*The EU Waste Framework Directive from 2018 requires Member States to establish systems for the separate collection of textiles by 1st January 2025. In this context, Extended Producer Responsibility (EPR) has seen increased political momentum, as collection itself will not solve the sector's problems. The need to make the polluter responsible is recognized by EU, and the upcoming revision of the EU Waste Framework Directive will include a proposal for harmonised EPR rules for textiles, with eco-modulation of fees (EC, 2022).

Originally, EPR is defined as a "policy principle to promote total life cycle environmental improvements of product systems by extending the responsibilities of the manufacturer of the product to various parts of the entire life cycle of the product, and especially to the take-back, recycling and final disposal of the product" (Lindhqvist, 2000, p.v). While the original idea considers the responsibility of producer across the entire life cycle of the product, for a long time, the objective of retaining the primary value of products has been linked to waste prevention, which is the main priority of the waste hierarchy, as laid out in the earlier version of the EU Waste Framework Directive, 2008/98/EC (Maitre-Ekern, 2021). This approach is too narrow if systemic change is desired. The experiences from other sectors across the globe also show that the incentives provided by EPR scheme are limited when it comes to promoting upstream changes (Micheaux & Aggeri, 2021; Maitre-Ekern, 2021; Laubinger et al., 2021). Additionally, there are no evidence available, that the various EPR schemes operating today aim to deliberately regulate short-lived products, such as FF. The several legislative measures currently proposed in the EU Textiles Strategy (e.g., the Ecodesign Directive, PEFCR) focus on the product design and end-of-life strategies, and do not address the essential questions of whether products are needed, whether they are used and for how long. Hence, they do not address the root causes of the problems.

## Proposal: Extending producers' responsibility via Targeted Producer Responsibility

Targeted Producer Responsibility (TPR) is a proposal for criteria for EPR fee-modulation to affect the production volumes and FF. The TPR proposes a new approach to eco-modulation by incorporating data on used textiles from streams such as household waste and donated textiles. The TPR fee is based on information on the quantity, age, and recycling costs of textiles according to the EU waste hierarchy, differentiated at brand level. TPR is therefore in line with the 'polluter pays' principle: those who produce clothes that are used the least or never at all, and/or clothes that are difficult or expensive to recycle, pay the most. As more textiles are collected for reuse and recycling in Europe, and utilised at higher levels of the waste hierarchy, costs will increase, and producers will have to contribute to these costs.

Measuring the average lifetime of a product is central to TPR. This measurement should be conducted when a product goes out of use (discarded or donated) by using picking analysis, which is a type of waste audit (Nørup et al., 2018). Based on waste picking analyses, an average usage timespan can be estimated. It requires that the production date is included in the labelling of clothing, a long overdue requirement. The time-lapse from when the product is put on the market until it goes out of use will give the manufacturers a score which is multiplied by the volumes of the various brands or other suppliers on the market. In addition, textile waste analyses provide knowledge on textile consumption and textile waste and might be important for research on durability.

Overall, there is a growing interest in durability of textiles both academically and in regulation, but it is still debated how to measure and integrate this in policy. We agree with Vanacker et al., (2022) that there is a lack of methods for measuring durability in the current literature, but we disagree in the usefulness on discussing extrinsic (or emotional) as something separate. The important difference is whether the measurement looks to the future based on various design parameters (including what is called the emotional or extrinsic) or looks at it historically, when the use phase has ended. To our knowledge, the assumptions about design parameters' impact on durability have not been empirically validated (Maldini & Balkenende, 2017). Design parameter is one of many elements that influence the lifetime of clothing. This element can be studied in terms of how people explain why their clothes go out of use (Laitala & Klepp, 2022). Another option is to use information about the garment, user, garment use practices, and aspects like price and number of new items in the wardrobe (ibid). In summary, durability is a result of many aspects of a product, such as product design, business model, marketing, and price. The advantage of TPR is that it summarizes all these parameters because it measures the actual product use. The brands that are most used are those that make products that people like and use and have a responsible business model.

TPR can be used and combined with different varieties of EPR and other political instruments. If it is to have the effect of reducing overproduction and making FF out of fashion, it depends on the fee being high enough to affect the producers, their business models, and down-stream decisions. However, it is not the size of the fee that distinguishes TPR from other EPR systems, but the way it is calculated.

## Conclusion

We argue that to reduce the environmental impact of increased volumes of textiles measures should be developed that go beyond product design and life-prolonging and end-of-life strategies. TPR shows how the facts about consumption and the use phase, could be embedded in the design of eco-modulation fees. Picking analyses ensures that the instrument is based on empirical facts rather than assumptions. The extent to which it will have an impact on FF, will depend on the size of the fee, the larger, the more effective. That is, it will be expensive to put goods on a market that will not be sold, will be bought but not sufficiently used or not used at all. TPR addresses the misunderstood fact that the use phase is important, but that more durable products do not necessarily mean less production.

The TPR concept contributes to the collection of knowledge and data on the use and durability of products and can therefore also have a positive impact on other policy measures, such as the PEF, the Ecodesign Directive and LCAs. We hope that TPR concept inspires policymakers to consider incorporating empirical insights from use and end-of-life phase into environmental regulation of products on the EU market. Finally, we hope the proposal inspires additional researchers to investigate the use phase and waste streams to create better data sets for measuring product lifetimes. and managing textile and other products flows.

## Acknowledgments
The paper has been produced within the project Wasted Textiles at SIFO funded by The Research Council of Norway and Norwegian Retailers' Environment Fund. The authors are grateful to the following experts for their contribution to the development and/or justification of the TPR proposal: Jens Måge, Lisbeth Løvbak Berg, Kirsi Laitala, Anna Schytte Sigaard, Kate Fletcher and Irene Maldini.

# Thinking beyond circles: Developing visual research methods for circularity in design education

**Laura Knight[(a)], Kate Goldsworthy[(b)], Sanne Visser[(c)] Cathryn Anneka Hall[(d)]**
a) Associate Researcher, Centre for Circular Design, London, UK
b) Professor of Circular Design and Innovation, Centre for Circular Design, London, UK
c) Researcher, Centre for Circular Design, London, UK
d) Postdoctoral Researcher, Centre for Circular Design, London, UK

**Keywords**: Visual communication; Lifecycle visualisation; Circular economy; Design research; Design education.

**Abstract**: This paper presents a case study of a material-lifecycle design project developed between educators, researchers and industry. Communicating and conceptualising circularity presented an opportunity to expand the reach of the research into a curriculum intervention. The project invited graphic design students to visualise a product lifecycle for a circular textile industry client - Piñatex. This paper explores the challenges of communicating circular lifecycles to non-expert audiences. It is acknowledged that there is a need for new kinds of designers in practice-based research. Therefore, the paper presents examples of new knowledge that visual communication methods, more traditionally taught in graphic design programmes can bring to research. Drawing on practice-based iconic research methods, which in contrast to theory-driven research enabled the production of images as a means producing knowledge about visual communication. Through an after-action review, the research demonstrated three surprising approaches to communication of circular processes that typically creates diagrams with icons in a circular shape. Through working with non-experts, the research exposed the client and the research team to range of visual approaches, namely, symbolic, non-circular and quantitative visuals. The research found that visual communication methods have the potential to play a pivotal role in development of new visual languages for circularity. It concludes that visual research methods can bring different design disciplines closer and build a stronger educational base for the transition to a circular economy.

## Introduction

In their report, "Beyond Net Zero: A Systemic Approach to Design" the UK Design Council emphasises the vital role that designers will play in building '*a bridge between technological research and innovation and their application to social practice (UK Design Council, 2021:6)*.' collaborative research, bringing together different disciplinary knowledge and methods, is increasingly understood as key to working with complexity and has been identified as '*particularly significant'* for sustainability research (Peukert, 2022). Literature from the field of practice-based design research also acknowledges the need for a new type of designer; with the 'expanded capacity' to undertake and participate in research (Vaughan 2017).

In design education, this calls for innovative approaches to teaching and learning, combining traditional design skills with sustainability literacy and contextual transdisciplinary knowledge (Peukert, 2022).

This paper presents a case study of a material-lifecycle design project developed between educators, researchers, and industry. The project was situated as part of ongoing research activity (IUK, Grant 78073, 2021) between University of the Arts London and material technology company Ananas Annam. A key challenge highlighted during the research was that of communicating circular product life cycles to non-expert audiences. The researchers wanted to explore the role

of teaching and learning in addressing this challenge and developed a curriculum-based project with graphic design students. The students - as non-experts in material design and circularity - were asked to develop visual alternatives to an Ananas Annam product life cycle.

## Visualising circularity

The main aim of design for circularity is to create closed loop systems, by extending the life of materials, products, and services in use, or retain their value through cascading, where materials or products become feedstock for another use (Ellen MacArthur Foundation, 2015). Circularity has been conceptualised and communicated in multiple ways, both within academia and industry, often through the visualisation of closed circles and interconnected flows of materials and production processes. Significant to one of the first circularity models is the distinction between biological and technical cycles, where one should not enter the other. This 'cradle-to-cradle' model was first highlighted by McDonough and Braungart (2002) and later incorporated into the Ellen MacArthur Foundation (2013) 'butterfly diagram'.

Subsequent visualisation models focus on material sourcing, production, use and end-of-life phases. Others highlight multidisciplinary stakeholders within each stage of the lifecycle like the Great Recovery project (RSA, 2016), potential business models within a circular economy (Accenture, 2014), or highlight the value retention options each flow offers (Reike, Vermeulen and Witjes, 2018). This last example, a type of combined cascading and supply chain mapping, shows the complexity of material and product lifecycles. A very different visualisation model is the 'Moonfish' circularity model developed by participants from the TU Delft (2014). This horizontal, figure-of-eight shape is focused on matching the value of the user with the value of the manufacturer.

As designing for circularity becomes more complex, visualisations have evolved into multifaceted and dynamic maps that go beyond material flows and include stakeholders, ecological values and the wider societal impacts. These visualisations combine icons and symbols with diagrams and labels in increasingly complex and interrelated ways. In the next section we will discuss how these visualisations of the circular economy are constructed with specific reference to three types of visual; diagrams, icons and symbols.

### *Dissecting circular visualisations*

Diagrams form the basis of most circular visualisations. They are particularly suited to this task as their primary function is to communicate interrelations (Stjernfelt, 2007). Walter R. Stahel's diagram from 1976 illustrated the life cycle of an industrial product within a circular economy. As shown by Fig. 1 is a classic example of a diagram; using only simple lines and labels to communicate its content.

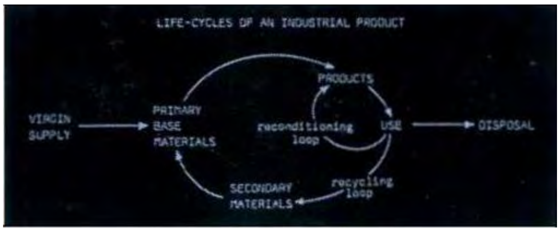

**Fig.1 Diagram of closed-loop industry – Walter R. Stahel 1976**

Subsequent visualisations of the circular economy incorporate layers of icons, symbols, colours and text over the top of a diagrammatic base; transforming the overall visualisation into something more broadly described as *infographic*.

Icons are consistently used in infographics. Historically, the term icon describes graphics that are literal visual descriptions of the objects they represent. However, they are increasingly used to represent more abstract or nuanced concepts. An example can be found at the centre of the EMF Butterfly diagram with two icons representing a 'consumer' and a 'user'. In absence of a visual idea that could communicate these ideas directly, two visual ideas are combined. The consumer icon combines a person with a barcode (Fig.2), the user combines a person with a digital interface (Fig.3).

**Fig.2 Icon for consumer. Fig.3 Icon for user. © Ellen MacArthur Foundation (2013)**

Circular visualisations also incorporate symbols, often alongside icons. The visual relationship between a symbol and its object is less direct. Symbols are used when no concrete object exists. We can see this Fig. 4 in the biological cycle of William McDonough and Michael Braungarts Cradle to Cradle visualisation. The visual representing 'plants' is iconic –literally a plant. However, the visual representation of 'biological nutrients' is encoded in a symbol. Here the relationship between the visual and the concept must be recognised to be understood.

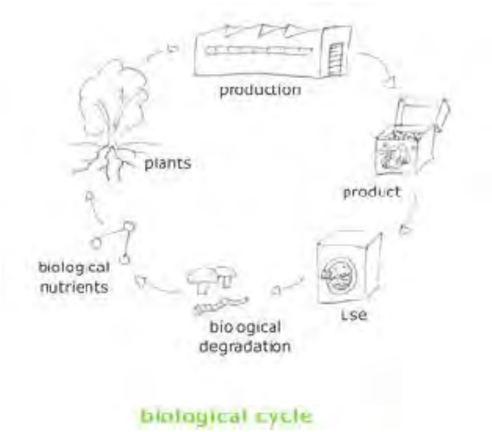

**Fig. 4 Cradle to Cradle Diagram.**
**© William McDonough and Michael Braungart**

### *Increasing complexity*

Circular visualisations often need to combine concrete and abstract ideas and visualise them in both sequence and interrelation. In many circular visualisations, symbols and icons are combined with text-based labels to support the communication. This layering of diagrams, icons and symbols with labels makes the task for the non-expert viewer quite complex. As designing for circularity becomes more complex, designers will need to respond with an increasing level of visual innovation. Johana Drucker suggests that this will require a break with the 'literalism' of current representational strategies, exploring alternative visual languages that connect non-experts with the content in new ways. (Drucker, 2014)

## The Piñatex Case study

This paper describes research conducted to explore this idea of visual innovation. Developed in collaboration with Ananas Annam focussing on the lifecycle of their product Piñatex. This product is made of fibre from the leaves of the pineapple plant. After pineapple harvests, the long fibres of the leaves are extracted, purified and undergo several processes to create the non-woven mesh that forms the basis of Piñatex products. The focus of the project was to use the existing forms of icons, symbols and diagrams to generate alternative versions of the Piñatex product lifecycle.

Working with Graphic Design students, the project's aim was to explore what new design knowledge, visual communication methods could bring to the challenge of conceptualising and communicating circularity. This live brief asked the students to explore alternative visualisations of the Piñatex lifecycle with specific focus on nine key stages in the process; harvesting, extraction, purification, meshing, coating, finishing, degrading, shredding and recycling.

## Methods

This research was conducted in two parts. Firstly, a live brief was designed and delivered by the Course Leader (Author 1) in collaboration with researchers at the Centre for Circular Design (Authors 2 and 3).

Secondly, the Course Leader and researchers (including Author4) conducted an after-action review (Morrison and Meliza, 1999) to reflect on the process and the insights generated through the process. Analysis focused on what was specific or unique about the ways that participants had approached the problem as non-experts. The outcomes produced by the students are used in the paper to expand on the insights generated.

The project methodology used *'the systematic creation of visual variations'* (Renner, 2017:5) as a means of producing knowledge about visual communication, exploring how '*the practical knowledge of visual communication contributes to the understanding of how images generate meaning'* (Schubach, 2017:14).
The methods used by the students included:

- mark-making
- visual description (icons)
- visual abstraction (symbols)
- visual arrangement (diagramming)

Project activities took place online over the course of one week. An initial briefing from the researchers (Author 2) was followed by three online studios. Students applied different visual research methods over the course of the week to produce a visualisation of the Piñatex lifecycle. Generative processes and visual prototypes were collated on a collaborative Miro workboard. All participants were given the choice of whether to participate in the research and written consent was sought for their work to be shared beyond the project.

## Findings

The participants were asked to produce visual representations based on a written description; therefore, their visualisations were based on their own (non-expert) interpretations of the content. This resulted in some new and surprising visual approaches to diagrammatic, iconic and symbolic forms that exposed the client and the research team to a range of visual approaches. Three key themes were identified in the after-action review and the insights that they generated are discussed below with reference to specific visual examples.

### *Theme 1: Symbolic vs iconic*

The icon and symbols, created by the students, visualising the nine key words in the lifecycle (harvesting, extraction, purification, meshing, coating, finishing, degrading, shredding and recycling) were surprising in their range. It was specifically noted that very few participants adopted more literal icon-based visual approach of existing circular visualisations. Rather, a symbolic approach was used.

Fig.5 is an example that used symbols rather than icons, where the final visualisation combines a set of simple symbols with labels over a simplified diagrammatic base. The insight for client and researchers here was that despite being simplified and symbolic, this visual language was still 'readable' – both as a circular process and in terms of its individual stages. As circular visualisations usually combine both icons and symbols within diagrams in increasingly complex and interrelated ways, a simplified symbolic form (as demonstrated Fig.5) could be further explored with specific audiences.

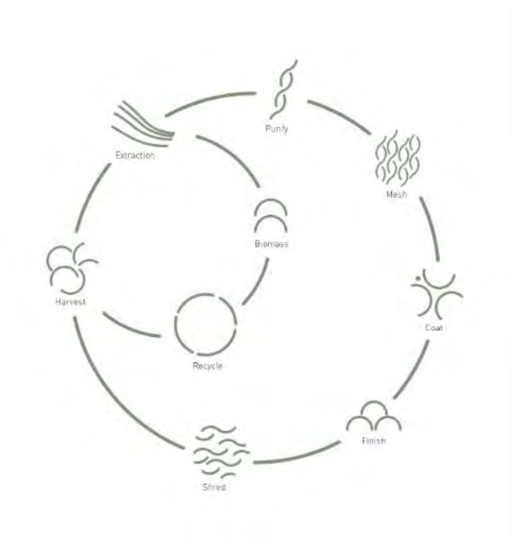

**Fig 5. Final Piñatex diagram - Jie Li**

Two further examples broke entirely with the literalism of existing approaches to circular visuals. In Fig.6 the imagery is abstract and yet iconic - constructed from marks made through direct experimentation with pineapple fibres. In Fig.7 the imagery is digital but visually suggestive of textile fibres. Graphically, both examples (Fig. 6 and Fig. 7) could be described as '*symbolic* of the processes' in that they are abstract rather than literal visual representations of each lifecycle stage. However, both examples (Fig. 6 and Fig. 7) also succeed in being visually *iconic* of the subject matter. The form of these visuals are suggestive of the subject being discussed, in this case textiles made from pineapple leaf fibre.

The insight for the researchers was that infographic approaches, while effective at delivering information, can be visually homogenising, often failing to visually place the circular design process in a specific context. As circular design is increasingly applied within different industries and fields, further research could explore how the visual approaches might better communicate the connection between application and context.

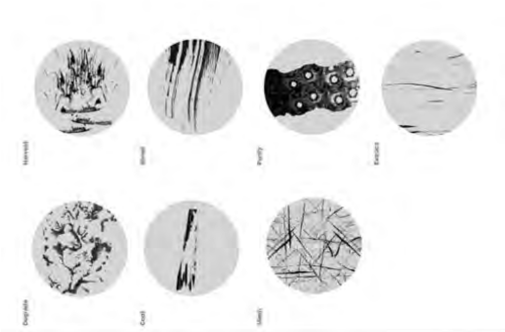

**Fig 6. Visual language - Siriwan Champorn**

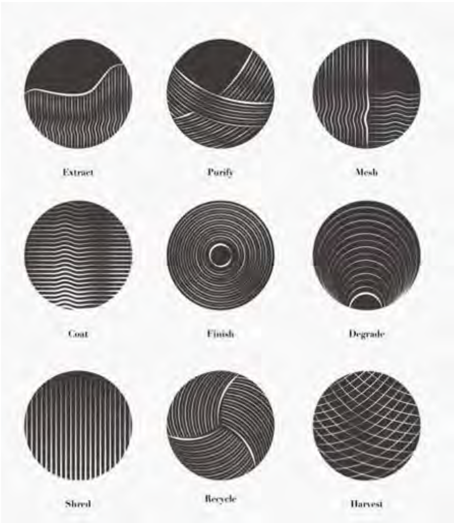

**Fig 7. Visual language - Ji Zhou**

### *Theme 2: Circular vs. linear*

Just over half of the visualisations generated in the project uses a circular diagrammatic base. For example. Fig. 8 shows a participant's re-visualisation of the client's existing lifecycle. It uses the typical approach of using a circular shaped diagrammatic base with iconic imagery for each lifecycle stage.

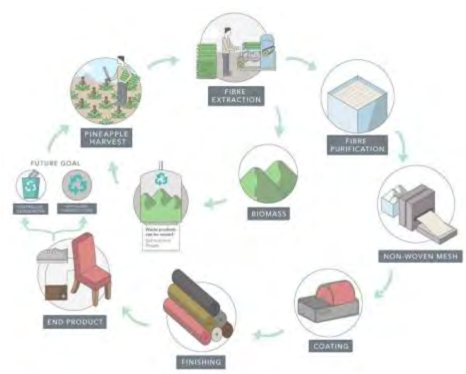

**Fig.8 Pinatex lifecycle visualization © Ananas Annam**

However, the remaining visualisations broke with the visual 'circular bias' of the field. An example that used a non-circular base was Fig 9. Consisting of straight lines, it flows downwards to a rectangular recycling loop that feeds back up again.

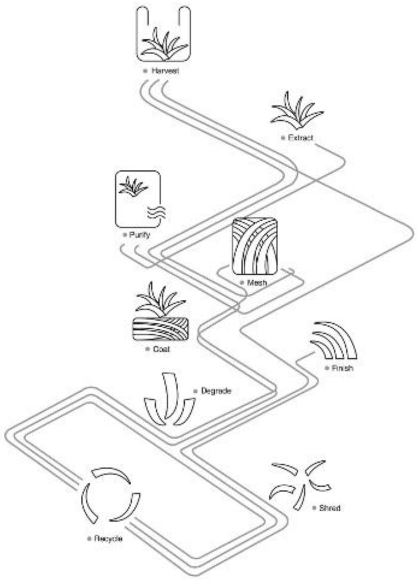

**Fig 9. Piñatex diagram - Jiayi Liu**

While not a technically perfect representation, the insight here was that a circular form is not necessarily the only way to communicate the circularity of a process and could be a useful approach to visualise processes that are not entirely circular or that have multiple complex interrelations. This demonstrates that practice-based iconic research, such as this, is a method to explore 'how the practical knowledge of visual communication contributes to the understanding of how images generate meaning' (Schubach, 2017:14). Further research might generate knowledge on how to balance the complexity of a circular process with the complexity of the visual for specific audiences.

### *Theme 3: quantification*

The final theme that presented itself was the incorporation of quantitative data in the visualisations. As discussed in the introduction, Bianchini et al. (2019) have highlighted that many circularity visualisations do not embed a 'quantification' as part of their communication. Fig.10 and Fig. 11 addressed this in different ways. In Fig.10 this was achieved illustratively using accessible visual comparisons e.g. transporting leaves = 104 elephants.

**Fig 10. Piñatex visual language - Jiaoyang Zhang**

In Fig.11 the approach was both more experimental and yet more classically quantitative. Echoing the visual form of a bar graph, it represented the CO2 emissions of the different stages of the lifecycle. The height of each bar represented the duration of the process, and the width represented a banded weight of CO2 emissions (Fig.11).

**Fig 11. Piñatex diagram - Siriwan Champorn**

The insight highlighted in the review stage was that approaches to quantification are an important area of innovation in circular lifecycle visualisation. Bianchini at el (2019), highlight existing visualisation types that could offer input here. However, further research might consider where new visualisation approaches are needed to meet the requirements of different contexts.

## Findings and Next Steps

The review of the participants work highlighted the value of the non-expert perspective for the client and created a discussion about the potential value that design practice, that uses visual methods, could have when implemented by expert practitioners.

Working with communication designers, the research demonstrated that their methods could play a central role in the development of new visual languages for circularity with a particular emphasis on their communicative potential for specific audience. This points the need for further research into how the teaching of visual research methods in design education can support designers across disciplines in connecting research and innovation to social practice.

Overall, this project highlighted the broader utility of visual research methods in bringing design disciplines (such as, material design and graphic communication design, as in this research) closer. It concludes that this can build a stronger educational base for the transition to a circular economy.

## Conclusion

Through a designed teaching and learning intervention, this project explored the new design knowledge that visual communication methods might bring to the challenges of communicating a circular lifecycle.

Graphic design students applied a sequence of visual research methods to interpret a circular lifecycle. Analysis of the visuals was conducted through an after-action review (Morrison and Meliza, 1999). While many of the resulting visualisations were less-than-perfect technical representations; the project resulted in three surprising approaches to communication , namely symbolic, non-linear and quantitative. This exposed the client and the research team to a range of visual approaches produced by non-experts.

The research found that visual communication methods have the potential to play a pivotal role in development of new visual languages for circularity. It concludes that visual research methods can bring different design disciplines closer and build a stronger educational base for the transition to a circular economy.

# Agent-based simulation for circularity assessment of consumer durables: consequential environmental impacts, product flow and stock, and user behaviours

**Ryu Koide[a,b,c], Haruhisa Yamamoto[a], Keisuke Nansai[a], Shinsuke Murakami[b]**
a) National Institute for Environmental Studies, Tsukuba, Japan
b) The University of Tokyo, Tokyo, Japan
c) Institute for Global Environmental Strategies, Hayama, Japan

**Keywords**: Agent-based Model; Circularity Assessment; Consequential LCA; Consumer Behaviour; Circular Economy Strategies.

**Abstract**: The transition to a circular economy (CE) requires a tool to support the design of CE initiatives by evaluating the expected impacts on circularity and the environment. The present study proposed an agent-based model of product circulation and consumer behaviour in the CE, simulating the dynamic diffusion of product-service systems (PSS), product flows and stocks, and consequential environmental impacts. The model was able to simulate the consequences of introducing seven types of CE strategies – reuse, leasing, rental, sharing, refurbishment, upgrading, and repair – considering their synergies and coexistence in society. By endogenising the bounded rational decision-making processes of consumers and social influences in the model related to the product life cycles, the model could simulate the impact of introducing CE strategies with promotional measures that trigger behavioural changes, such as pricing and information provision. With a preliminary case study on home appliances, the simulation model demonstrated the diffusion patterns of new PSS, product flows and stocks, and environmental impacts over the decades of the simulated time. The model provides a practical tool for the research community and practitioners for prospective circularity assessment of multiple CE strategies.

## Introduction

In recent years, the transition to a circular economy (CE), which effectively utilises the value of products and reduces waste and pollution, has attracted attention (Ellen MacArthur Foundation, 2013). The introduction of various CE strategies such as refurbishing, reuse, repair, rental, and sharing is expected to produce a transition from the traditional sell-off of new products to CE-based business models (Salvador et al., 2021). Although these new business models will significantly change the way products are supplied and used, consumer choice behaviours in CE are not yet well understood. Most existing studies lack methods to explore interventions for the effective diffusion of CE (Camacho-Otero et al., 2018).

Although introducing product-service systems (PSS) is expected to contribute to environmental sustainability, there is concern about the rebound effect, where some of the effects are cancelled out (Tukker, 2015). Factors related to consumer behaviour, such as frequency of use, product substitution, and product lifetime, determine such rebound effects, and a better understanding of consumer behaviour is essential for designing a sustainable CE (Koide et al., 2022). Consumer behaviour and heterogeneity play important roles in the environmental impact of products (Polizzi di Sorrentino et al., 2016). Given the potential trade-offs between circularity and environmental impacts, it is essential to evaluate both environmental impacts and circularity in a consistent way (Harris et al., 2021). However, previously employed methods, including life cycle assessment, material flow analysis, and discrete event simulation, are not capable of quantifying the consequential changes in the environmental impacts and circularity, considering the dynamics and heterogeneity of consumer behaviour.

An agent-based model was developed in the present study to simulate consumer behaviour and the circulation of consumer durables with the introduction of PSS in the CE, as well as to quantify the diffusion of newly introduced PSS, product circularity, and their environmental impacts. This paper presents an overview of the model structure and demonstrates the use of a simulation model with numerical examples of consumer electronics to compare CE strategies and promotional measures.

## Methods

### *Overview of the simulation model*

The agent-based model developed in this study was intended to simulate the diffusion of PSS and the associated changes in circularity and environmental impacts in the product life cycles. Through simulation experiments, we examined the expected consequences of the scenarios by assuming the introduction of different CE strategies and promotional measures. Seven CE strategies were examined: repair, refurbishment, upgrade, reuse, lease, rental, and consumer-to-consumer (C2C) sharing.

In this model, households, products, and circular supply chains were represented as entities so enabling the simulation to capture their diversity and interaction. The major state variables of these entities are listed in Table 1.

| State Variables | Description |
|---|---|
| **Household entities** | |
| Utility function | Partial utility weights for attributes related to PSS acquisition, repair and discharge choices |
| Obsolescence function | Shape and scale parameters of the Weibull distribution for relative obsolescence |
| Awareness set | Alternatives known by households |
| Consideration cost | Cognitive costs of consideration of additional alternatives |
| Previous choice | Records of the previous choice for habituation |
| Word-of-mouth reception | Frequency of receiving word-of-mouth |
| Products in use, on standby, and in hibernation | Status of products kept by households |
| C2C sharing status | Products available for C2C sharing |
| Social network | Social network topology of households |
| **Product entities** | |
| Circularity status | Product circulation status (e.g. refurbished, reused) |
| Ownership status | Type of ownership (e.g. leased, rented, owned) |
| Years since manufacturing | Years since manufacture of the product/component |
| Failure status | Failure status of product/component |
| Process inventory | Records of processes along product life cycle (e.g. manufacturing, operation, repair, preparation for reuse) |
| **Circular supply chain entities** | |
| Leased and rented products | Products leased or rented to households |
| Products in stock | Products awaiting sales, leasing, or rental |

**Table 1. Entities and state variables (excerpt).**

The time step of the simulation models was set to one month, with an overall simulation period of several decades. NetLogo (Wilensky, 1999) was used to implement the simulation model.

### *Consumer behaviour model*

The consumer behaviour model in this study covered three types of choice behaviours in CE: i) acquisition of a PSS, ii) repair choice in case of failure, and iii) discharge choice of end-of-use products. In this study, the bounded rationality of consumer behaviour was incorporated, assuming that consumers gradually narrow down available alternatives through an information search on social networks, formulating awareness and consideration sets with the roles of social influence by acquaintances, as summarised in Figure 1.

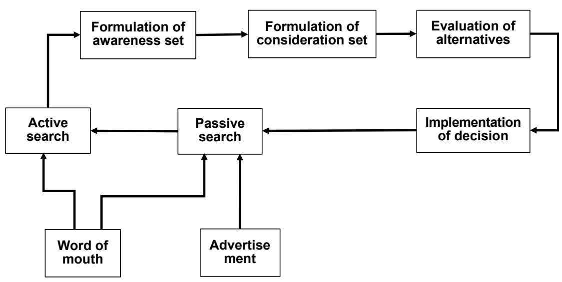

**Figure 1. Overview of the consumer behaviour model.**

The model processes related to consumer behaviour were summarised as follows:

- Households received word-of-mouth through their social networks regarding newly introduced PSS and the number of acquaintances who use the PSS with a certain given probability (passively every timestep and actively right before decision-making).
- Households received advertisements from businesses and the government with a certain given probability.
- Consumers did not rationally consider all known alternatives in the final stage of decision-making. Instead, they narrowed down the alternatives following the Roberts–Lattin model of consideration set formulation (Roberts & Lattin, 1991). Each alternative was considered in the final decision only when its additional expected utility exceeded the threshold of cognitive costs of consideration.
- Households made a final decision based on the random utility theory. PSS attributes such as price, years since manufacturing, circularity status, ownership status, and free repair warranty period determined the utility of the alternatives.
- When a significant number of acquaintances in a social network used a specific alternative, consumers preferred to choose the same alternative (social influence).

*Product circulation model*

The product circulation model simulated the processes of manufacturing, use, discharge, and preparation of products encompassing seven CE strategies (repair, refurbishment, upgrade, reuse, lease, rental, and C2C sharing), as shown in Figure 2. In the model, these CE strategies could be introduced in combination; for example, repairing reused products and leasing refurbished products.

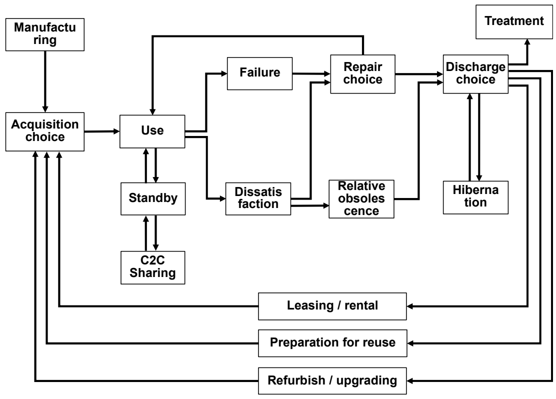

**Figure 2. Overview of product circulation model.**

The model processes involved in the product circulation are summarised as follows:

- Newly manufactured products were offered to consumers either as owned (purchased) or not owned (leased or rented) according to the choice results of the consumer behaviour model.
- A product was considered obsolete either because one of its major components failed or because of relative obsolescence, according to the Weibull distribution. Using a heterogeneous setting of scale parameters, the model considered diversified obsolescence patterns across components and households.
- For products that were not necessarily always operated within a household but were used intermittently, the operation and standby states of the product were updated so that temporal use and sharing (rental and C2C sharing) were considered.
- If the products owned by households failed, they could be repaired according to the choice results of the consumer behaviour model.
- Products with relative obsolescence or those not repaired at the time of failure were collected by circular supply chain entities according to the choice results of the consumer behaviour model.
- The collected products were either refurbished (in some cases, with functional upgrades); prepared for reuse, lease, or rental; or treated for material recovery, depending on the introduced CE strategies.
- After the preparation process, products were added to the stocks of the circulating

supply chain and reflected in the consumer behaviour model as alternatives for acquisition choices.

- Processes during product life cycles, such as manufacturing, transport, operation, repair, refurbishment, preparation for circular use, and treatment, were recorded as inventory, which was used to quantify environmental impacts and circularity.

## Numerical Examples

*Scenario setting*

To illustrate the application of the agent-based model developed in this study, simulation experiments were carried out using two numerical examples of household appliances. Numerical example A compared the promotional measures for the leasing of a large refurbished household appliance. Here, price reduction, intensive advertisement, and improvement in service level (extension of refurbishability and repaired-part retention periods) were considered. Numerical example B compared the environmental implications of introducing different PSS (reuse, rental, and C2C sharing) for small household appliances. A list of scenarios is presented in Table 2.

The parameters for these numerical examples were set by assumption or by referring to literature values as far as possible. The experimental conditions were set at 2000 household entities for a simulation period of 30 years, with 100 computer experiments for each scenario.

*Results: diffusion of newly introduced PSS*

Simulation experiments with numerical examples successfully demonstrated that an agent-based model dynamically quantified user behaviours, product flow, stocks, and consequential environmental impacts in the CE.

For numerical example A, the dynamic diffusion of a newly introduced PSS through promotional measures, such as price reduction, advertising, and service level improvement, was quantified over 30 years of the simulation period (Figure 3). Here, the time taken to diffuse a new PSS differed according to the promotional measures (advertising was effective for early diffusion, while the effect of service level improvement was slower), and a synergetic effect was observed when multiple promotion measures were combined. When all measures were combined, bottlenecks in product circulation due to the lack of products to be collected for further refurbishment were observed.

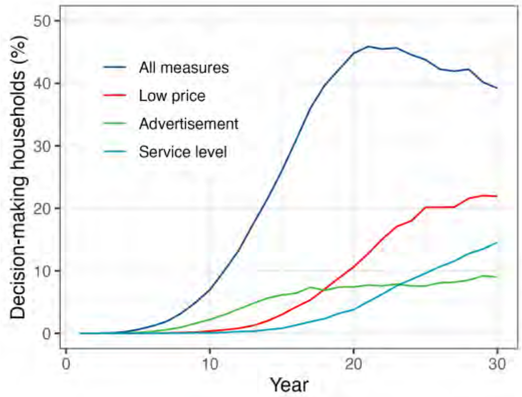

**Figure 3. Diffusion of newly introduced PSS with promotion measures (Numerical example A).**

*Results: product flow and stock*

To assess product circularity, the flows and stock of products under different forms of ownership and circularity status could be visualised, and various circularity indicators, such as product lifetime, reduction of waste, and repair rates, quantified.

In numerical example B, the stock of products used by households in society after the introduction of a PSS was quantified (Figure 4). Here, owing to a shift in ownership to the use of a product, the number of products in use actually decreased as the sharing service could fulfil consumer requirements with a smaller number of products.

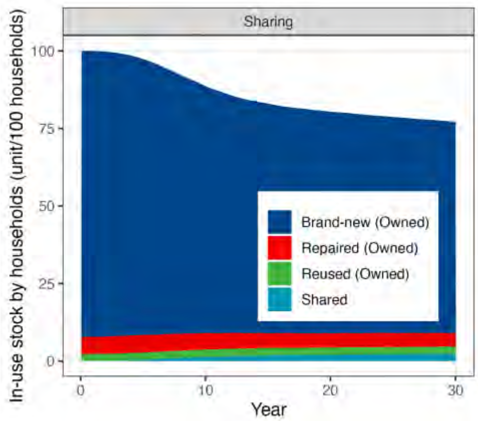

**Figure 4. In-use stock of products using a sharing service (Numerical example B).**

*Results: environmental impacts*

As the model simulated the diffusion of new PSS and product circularity status among heterogeneous consumers, changes in life-cycle environmental impacts as a consequence of introducing CE strategies could be quantified.

For numerical example B, the total GHG emissions with a breakdown of life-cycle phases over the last 10 years of the simulation period were compared for the three PSS types (Figure 5). This enabled the identification of hotspots, which were the main factors that increased environmental impact. Here, a backfire effect was observed, with a slight increase in GHG emissions due to the introduction of the rental compared with the reuse scenario, whereas overall emission reductions were expected in the sharing scenario.

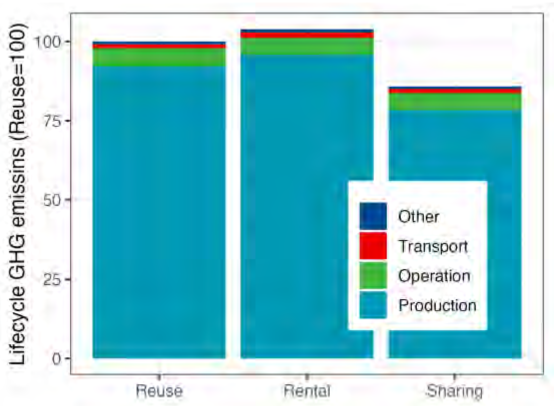

**Figure 5. Comparison of GHG emissions with three types of PSS (Numerical example B).**

## Discussion

The proposed simulation method allowed for the quantification of the consequences of product circularity and environmental impacts in various scenarios, including the introduction of new PSS and promotional measures, taking into account the dynamics and heterogeneity of consumer behaviour related to the product life cycles. The model was shown to be useful for comparing the consequences of different CE strategies and examining the effectiveness of promotional measures that focus on shifting consumer behaviours through numerical examples. The dynamic diffusion patterns of PSS were simulated with changes in product stocks and their environmental impacts calculated.

The agent-based approach used in this study enabled more precise modelling of consumer behaviours and their interaction with product systems in CE, which is difficult to achieve with existing methods. First, the quantification of environmental impacts and circularity indicators using the proposed method dynamically quantified the consequential impacts on society of an intervention over a simulation period of several decades. Such assessments are typically not covered by conventional life cycle assessment or material flow analyses. Second, the proposed model could examine the effectiveness of various promotional measures such as pricing and advertising and consider the bounded rationality and heterogeneity of consumer behaviour. Such dynamic modelling of heterogeneous behaviours is not possible with other simulation methods, such as system dynamics and discrete-event simulation.

The model was designed for calibration using empirical data related to product lifetime, consumer choice, and life-cycle inventory. The application of simulation experiments to real problems using empirical data is a topic for future research. The agent-based model developed in this study is useful for deepening our understanding of the determinants of consumer behaviour, bottlenecks in product circulation systems, and the heterogeneity of consumer behaviour. The use of the model with real stakeholders is expected to support the design of an effective PSS and the evaluation of policy interventions for the shift to a CE.

# Layers of repair increasing the emotional durability of fashion and textiles

**Marta Konovalov[(a)], Julia Valle Noronha[b)], Kristi Kuusk[(a)]**
a) Estonian Academy of Arts, Tallinn, Estonia
b) Aalto University, Espoo, Finland

**Keywords**: Layers of repair; Fashion and textiles; Emotional durability; Craftivism; Co-creation.

**Abstract**: This paper explores our relationship with clothing and textiles from the perspective of mending. It asks how layers of repair can increase the emotional durability of fashion and textiles. It aims to rethink fashion and to create a caring environment through the act of repair, co-creation and craftivism. The paper presents a case study based on the exhibition *"Pikem suhe"* (A Long Engagement) at Kondas Centre, Viljandi, Estonia. The exhibition was formulated through co-design with the participating artists and the audience. The designers and artists exhibiting their work invited the public to participate in repair workshops, with the hope to support garment use time and enhance social well-being and emotional satisfaction. The works presented in the exhibition were accompanied by stories about the items of repair and provide the data on which this paper is based. The findings from the analysis of these written stories show repair being added layer by layer to loved clothes to prolong the relationship once the items start to wear out. The layers of repair can be seen as an embodiment of narratives from our prolonged relationship with clothes.

## Introduction

Different approaches to repair have recently emerged in the discussions within fashion, clothing and textile design practice as a means to support a transition to more sustainable futures (Durrani 2019). This research looks at the works presented in the exhibition *"Pikem suhe"* (A Long Engagement) at Kondas Centre, Viljandi, Estonia as a case study. The work is positioned in the context of design and crafts and seeks to open up the discussion and understanding of how a designer can facilitate emotional durability and support sustainability through layers of repair.

The paper departs from an overview of the literature in repair and prolonging the use phase of garments. Following, this research is exposed in terms of its methodology, the exhibition is explained and the findings are laid out. A discussion on the possible implications of the research results for the field of textiles concludes the paper.

## Literature review

Recent shifts in clothing and textiles production and consumption have led to a growing early discard of fully functioning goods. Chapman (2015) argues that one of the reasons for such early discard is the lack of emotional attachment, and notes that there is little point in designing long lasting products if consumers lack the desire to keep them. Studies have pointed out repair as a tool to prolong the use phase and contribute to cultural and environmental sustainability (Durrani 2019). In addition, Fletcher (2021) suggests that practices of care and repair can support a society-driven, bottom up approach to sustainable transition. Vankerschaver (2017) adds that the one-sided principle of perpetual growth must be replaced by a living dynamic of diversity and local knowledge can be united in a global system.

De Castro (2019) brings out the absurdity of us still seeing creative repurposing and revival of clothes as a badge of shame of poverty and need at the same time when now it is precisely the opposite. Donating clothes to charity stops is no longer an act of good will but an act of dumping responsibilities for the unwanted clothes (De Castro 2021). In the open letter to the fashion industry Ricketts (2021) brings out the problems with discarded and donated clothing. Chapman states that recycling is sometimes even an excuse for more rapid discarding and can encourage wastefulness (2015, p. 15). It is estimated that less than 1% of all textiles worldwide are recycled into new textiles. (European Commission 2015) Stained and moth-holed clothing cannot be recycled and is not suitable for donating to reuse centres. One of the few options we have to stop our clothing and accessories from ending up at the landfill is to rediscover some old wisdom, through mending and repurposing.

Durrani suggests communal garment mending events as means to slow down and extend the use of clothing that people already possess (2019). What if clothes and textiles are considered to be at their best if they show signs of use and damage? Wearing out gives the user a possibility to interact with the clothing by adding layers of repair as a sign of increasing value over time. Garments are `made` with each and every wear (Sampson 2020).

This research is aiming to contribute to a system for the clothes to live their own life in the hands of the user or multiple users, each adding up a new layer. In the European Commission Circular Economy Action Plan, repair is stated as one of the ways of redefining the consumption patterns and transitioning to a regenerative system (European Commission 2015). Unfortunately the regularity of domestic mending is reducing but participation in repair events has been growing (Durrani 2019). Individual consumers are being empowered with skills and the social aspect is important when making something together (Hircher et al. 2018). Craftivism, the more powerful more personal approach to activism can pioneer change (De Castro 2021).

Clothes represent the actual worldly reality of lived experience (Fletcher 2019), especially when we approach them as experiences rather than as things (Sampson 2020). Sampson (2020) describes wear and use not only as a record of the wearer´s lived experience but also as embodiment of stories experienced in a relationship. This research develops the idea further to layers of repair possibly seen as embodiment of the caring relationships in a long engagement.

## Motivation and inspiration

In March 2023 Marta Konovalov was elected as UNESCO Creative City Viljandi Master of Crafts for one year. Her aim was to contribute to cultural and environmental sustainability by focusing on textile repair. One of her contributions in this role was curating the exhibition "*Pikem Suhe"* (A Long Engagement). Inspired by the simple but radical idea of Kate Fletcher and Mathilda Tham (2019) who ask us to put the health and survival of our Planet Earth, and consequently the future security and health of all species including humans, before industry, business and economic growth. Believing that we do not only need to take radical action but we need a sense of optimism to be able to proceed with our actions. Instead of waiting for a shift in the industry level, everyone can contribute by looking after their clothes with care and repair (Fletcher 2021).

## Methodology

The research was carried using a qualitative multi-method approach having the exhibition as a tool for data collection. Data was produced with participants via workshops, focus group interview, patient cards and visual documentation (photos). In order to engage the audience as research participants an exhibition was designed, where the audience's contributions set the exhibition in a state of flow and constant development. The exhibition design evoking a maker-space setting supported such engagements via workshops and discussions and allowed for a data collection environment, enhanced audience engagement, as well as a setting to popularise repair.

## About the exhibition

The exhibition "A Long Engagement" took place at Kondas Centre, Viljandi, Estonia from 16.11.2022-28.01.2023. This exhibition explored our relationship with clothing and textiles from the perspective of mending. Aiming to rethink fashion and to create a caring environment through the act of repair, co-creation and craftivism.

On the first day the exhibition was not finished (Figure 1). On its opening day there were works from seven designers, craftspeople and artists — Maris Taul, Marta Konovalov, Anna-Maria Saar, Kelian Luisk and Marika Jylhä, Terje Meisterson and Gary Markle.

**Figure 1. Gallery setting on the first day of the exhibition with the works of Maris Taul. All photos by Kärt Petser.**

Marta Konovalov makes mending visible in her creative practice with the aim to remind repair as a philosophy and inspire others towards the act of repair for prolonging the use phase of fashion artefacts. The works exhibited by her were also intended to function as samples of the workshops. The socks and footwear are both mended in similar methods to outline the possibilities to regenerate broken or worn out textile surfaces (Figure 2). Aiming to create an aesthetic that values mending, hoping that visible mending is more than a trend.

**Figure 2. The darning samples by Marta Konovalov aligned with the works added to the exhibition by the audience and workshop participants.**

The exhibition also outlined the need to repair the way we consume and produce fashion.

Gary Markle´s work is intended to mend connections between people and the clothing they consume by asking them to slow down and engage in a process of remaking material (Figure 3.). Hoping to educate consumers to extend the use time of garments but also to enhance social well-being, providing emotional satisfaction which can even replace some of the emotional effects of fast fashion consumption (Hircher et al. 2018).

**Figure 3. Engagement in a process of remaking material on tools by Gary Markle.**

The public and the workshop participants were asked to contribute to the exhibition by adding their previously made work of repair or a mending project from the workshop. The works are accompanied by stories about the items of repair in the form of written interviews. The exhibition space became a workshop where one can repair, learn how to mend and to discuss the well-being of our planet, ourselves and our clothing while making together. The audience was invited to a discussion over our roles in our relationship with textiles and clothing — are we the consumers, owners, wearers or are we in a caring relationship?

## About the workshops

Six workshops focusing on textile repair were organised during the exhibition. In three of them people attended as groups and in other cases people came out of their personal interest. There were more than 800 people who visited the exhibition and 89 workshop participants in total.

The aim of the workshops was to teach and learn repair techniques, mend together and to discover repair as means to revive our relationship with clothing. In addition to creating an environment where local craftspeople can interact and exchange knowledge.

The workshop by Maris Taul provided inspiration from the common practice of our ancestors and the mending techniques popular in the beginning of the 20th century. Marta Konovalov led four workshops, where the participants were reminded how basic techniques such as darning and swiss darning can give new life to clothing.

Anna-Maria Saar was teaching *sashiko*-inspired patchwork techniques based on her own personal journey of mending her clothes. Sharing her observation on the material and the time needed for the practice. The workshop also functioned as a focus group interview. The position of being an active participant instead of teaching the methods for repair allowed to lead the conversations and ask questions on why and what people choose to repair.

## Findings

During eleven weeks 30 works of repair were added to the exhibition. 12 of the added works were collected from the mending workshops and 15 people brought their independent work of repair to the exhibition. Three artefacts mended at repair workshops organised outside this exhibition were also presented. We also asked the public and the workshop participants to contribute to the exhibition by telling stories about the items of repair.

Some of the artefacts brought to the exhibition have had previous relationships with other people. In the case of the second-hand store findings these people are not known. Other items had been made, worn or repaired by someone dear. “Repairing something is an act of love… It's an act of care for that object, of course. But it's often an act of love for the person that the object belongs to.” (Treggiden 2021). There was a work of repair that functioned as a journey of personal healing. Repair is also an act of emotional repair (Treggiden 2021). The act of repair can be seen as a form of positive activism that leads to emotional well-being.

Many of the added works had been repaired multiple times, sometimes by different people (Figure 4). The reason for mending the exhibited artefacts was always them being worn out or having holes. Durrani approaches repair as mending something that is broken, not alterations (2019). In the case of all the works added to the exhibition the same approach occurred. It was later discovered that none of the mending techniques used had been done with the help of a sewing machine. Hand stitching, darning and handmade patchwork was applied instead.

**Figure 4. The inside of a sweater with repairs from three different people.**

Most of the participants had previous experience in textile mending and also the technical skills. It was the mindset and philosophy of repair as means of care that needed relearning. Often repair of the items occurred, because the workshops took place or people attended as a group. But co-creation meant more than just mending together in the same space. There were sweaters co-mended in the belief of increased emotional value and socks darned by different menders in the workshops. Some people needed to learn the basic techniques of mending and most to remember repair as an option before discarding.

It also happened that people skillfully mastering the techniques of repair choose not to use it in their daily practices, because there was a period in their life where they had no other option. Some of the participants stated that they choose what they repair, meaning that cheap and poorly made fast fashion items are not worth the effort. Other practitioners mediate the repair activities as a creation or an act of performative art, thus making the hidden work visible. The humble act of repair (Ax 2018), holds within an essence of care, creativity and also power (Durrani 2019). De Castro (2021) also argues that when it comes to the emotional relationship, everything is worth keeping and repairing something that was designed to be disposable strives towards an overall improvement of the system.

Each repair marks a sometimes visible, often tangible caring engagement. In the case of one dress the repair added in a previous relationship got to be unnoticed for years by the current wearer of the dress (Figure 5.). It only got noticed when a new act of repair was needed.

Each repair marks a sometimes visible, often tangible caring engagement. In the case of one dress the repair added in a previous relationship got to be unnoticed for years by the current wearer of the dress (Figure 5.). It only got noticed when a new act of repair was needed.

**Figure 5. The dress repaired by Anna-Maria Saar where layers of repair are camouflaged by the pattern.**

When it came to textile and clothing the motivation behind the repairs was to prolong the possible use of the garment. The practices of use depend on the reality of our everyday lives (Vankerschaver 2017).

It was due to emotional attachment or sometimes also practical need that the relationships with these garments were prolonged. None of the relationships ended when the garment got damaged or broken. Often these items had already been mended before. It was also discovered that none of the works aimed to recreate the piece in its original state. They were under constant development through use, wearing out layers of repair (Figure 6.). Often these layers are applied by different people. This relates to the *wabi-sabi* philosophy where the notion of completion has no basis and also the role of the author is not considered the most important. In the *wabi-sabi* universe things are either devolving toward, or evolving from, nothingness (Koren 1994; Koren 2008). Through wear and repair clothes were in the making.

**Figure 6. A glove added to the exhibition by Jane Remm with multiple layers of repair.**

The works exhibited and analysed were limited by the ones that could be exhibited because they were not needed in daily use. For example one of artefacts, a woollen pair of socks, could not be exhibited due to the winter season and the participants' needs. These kinds of items most often represent the layers of repair.

## Conclusions

Adding the first layer of repair to clothes and textiles can lead to mending them again, because of the emotional durability created through care. Through co-creation, care and repair clothes can have a life of their own in long relationships with humans. The layers of repair can be seen as an embodiment of narratives from our prolonged relationship with clothes.
This could lead to future discussion over how the role of a designer could be seen if we shift our focus from making to maintaining. Also on how to rewrite the story of our clothes and to bring in new narratives of well-being, care and regeneration. Hopefully this research can widen

the boundaries of when a garment's use phase should end and begin.

## Acknowledgments

I wish to thank the Cultural Endowment of Estonia and the people from University of Tartu Viljandi Culture Academy and Kondas Centre whose help and support made this research possible.

# Circular Product Design Strategies, Principles and Guidelines for the Metal Sector

**Tamba Konteh[(a)], Fabrizio Ceschin[(a)], David Harrison[(a)], Alessio Franconi[(a)] Timothy Minton[(b)]**

a) Brunel University London, College of Engineering, Design and Physical Sciences, Brunel Design School, Design for Sustainability Research Group, London UB8 3PH, United Kingdom

b) Brunel University London, College of Engineering, Design and Physical Sciences, Mechanical and Aerospace Engineering, Institute of Materials and Manufacturing, London UB8 3PH, United Kingdom

**Keywords**: Circular product design, Strategies, Principles, Guidelines, Metal Sector.

**Abstract**: The rapid depletion of finite resources used to create short-life products and resource sustainability issues has generated profound global concern. Design in the existing linear economy (LE) has been identified as a major contributor to these problems as well as a crucial component in the transition from the LE to a circular economy (CE). Due to the unique material properties, manufacturing processes, and recycling issues of metals, the metal sector requires specific circular product design strategies (CPDSs), circular product design principles (CPDPs), and circular product design guidelines (CPDGs) to make long-lasting metal products. These metal products are to be designed to enable the circular flow of material resources, particularly aluminium and steel in a CE. There are currently no comprehensive set of CPDSs, CPDPs, and CPDGs for the metal sector to design long-lasting metal products that will enable circular flow of metal resources. This study, a project of the CircularMetal research centre, addresses these concerns with the identification of product design strategies, principles and guidelines from eco-design, mechanical design, and circular product design. These were adopted/adapted and systematised into a comprehensive set of clearly defined CPDSs, CPDPs, and CPDGs that were previously unavailable for the metal sector. They are then clustered around the various product lifecycle phases of the developed Circular Design Strategy Wheel, an adaptation of the Eco-design Strategy Wheel. The circular product design guidelines include aspects such as metal manufacturing processes, robotics, and other processes which enable the design of long-lasting metal products and circular metal resource flow.

## Introduction

Resource sustainability issues poses significant challenges for both present and future generations, especially considering that the global middle-class population is projected to reach approximately 5 billion by 2030, more than doubling its size from 2015 (Ellen MacArthur Foundation, 2015). The ways in which finite resources have been used irresponsibly to make short lifespan products to meet the needs of rising population over many decades, and for economic growth which is dependent upon material and energy consumption in the current linear economy (LE) has caused social, economic, and environmental problems (Hilson, 2010; Desing, Braun, and Hischier, 2020). These short lifespan products which have been designed with obsolescence as an inherent part of their design and manufactured from depleting finite raw material resources are mostly disposed after use (Allwood et al., 2011) with significant loss in material value and damage to the environment. These issues have generated an alarming global concern with individuals, academia, industry, non-governmental organisations, and both national and local governments including the United Kingdom (UK), seeking actively to provide solutions to these problems through diverse initiatives. Design has been determined to be the primary or a major contributor to the issues of resource sustainability (Papanek, 1972; Bocken et al., 2016) and identified as a key element in the transition from the existing LE to a circular economy (CE) whose advocates includes Stahel (2016; 2010), Murray et al., (2017), the Ellen MacArthur Foundation (2015), and Geissdoerfer et al., (2017). This has led to the development and implementation of various product design paradigms including product eco-design to enable long-lasting and sustainable product design, manufacturing, and behavioural change in consumption (Vezzoli et al., 2015; Ceschin and Gaziulosoy, 2016; 2019). Aluminium and steel are the most used and important engineering materials in the UK metal sector. They support other important industrial sectors including construction, automotive, aerospace, and other manufacturing industries. The uniqueness of their material properties, production and manufacturing processes, recycling challenges, and associated energy consumption, requires specific circular product design (CPD). However, a comprehensive body of CPD knowledge is lacking to address the issues of resource sustainability and circularity. Despite the availability of several generic product design and eco-design strategies, principles, and guidelines which exist to foster the design of long-lasting products and resource flow in a CE (Franconi, Ceschin, and Peck, 2022), there is still a lack of systematic CPD knowledge. Additionally, the available CPD knowledge is limited in scope and requires adaptation to address the design and resource sustainability issues associated with short-lived products that are discarded after use (Kirchherr et al., 2018) This research aims to fill this gap in knowledge in support of the UK government's aim to enable transition of the UK metal sector into a metal circular economy by 2050. As part of the CircularMetal research centre (one of the five CE research centres funded by the UK Research and Innovation), this study addresses the following research question: "What are the circular product design strategies, principles and guidelines that can be applied in the metal sector?"

## Methodology

*Literature Review*

A literature review was undertaken to identify existing traditional mechanical design, product eco-design, and circular design strategies, principles, and guidelines. The process of identification of these design strategies, principles, and guidelines utilised key words and strings including "Design for longevity", "Design for disassembly", "Design for remanufacturing", and "Design for circular supply chain". The literature search was done with host of synonyms in the strings using two search engines, namely Google Scholar and Brunel University's library which incorporates Scopus: the world's most comprehensive database of peer-reviewed literature that spans over every known and established discipline including design in both academia and industry.

After the relevant data had been collected, the classification, adoption and adaptation and systematisation of the circular product design strategies (CPDSs), circular product design principles (CPDPs), and circular product design guidelines (CPDGs) was undertaken.

*2. Classification of existing design strategies and principles into eco-design, general design, and circular design categories*

It was identified in the literature that strategy, principle, and guideline are terminologies which are often used indistinctly, and this causes some contextual ambiguity in product design. Therefore, it was necessary to provide definitions for these terminologies which are given below to make a distinction amongst them and avoid ambiguity in this study.

A product design strategy is a plan of activities or processes which are intended to achieve a desired design outcome.

A product design principle is a basic idea which serves as a proposed rule that when applied to the design of a product or system results in actions which help to solve a design issue or achieve a desired state or function of a product or system.

A product design guideline is a prescriptive recommendation or suggestion which aids the application of design strategies, principles or guides a course of action in the design process of a product or system.

The existing product design strategies and principles were classified into three categories: eco-design, circular design, and general design. This classification was done in two stages. The first stage involved categorising the product design strategies and principles into these three categories. The second stage involved correctly defining the terminology used in the literature and classifying the product design strategies and principles into their respective categories using the given definition and a Product Design Terminology Classification and Identification Matrix. Product design guidelines were not categorized, as they are prescriptive recommendations intended to help implement relevant circular product design

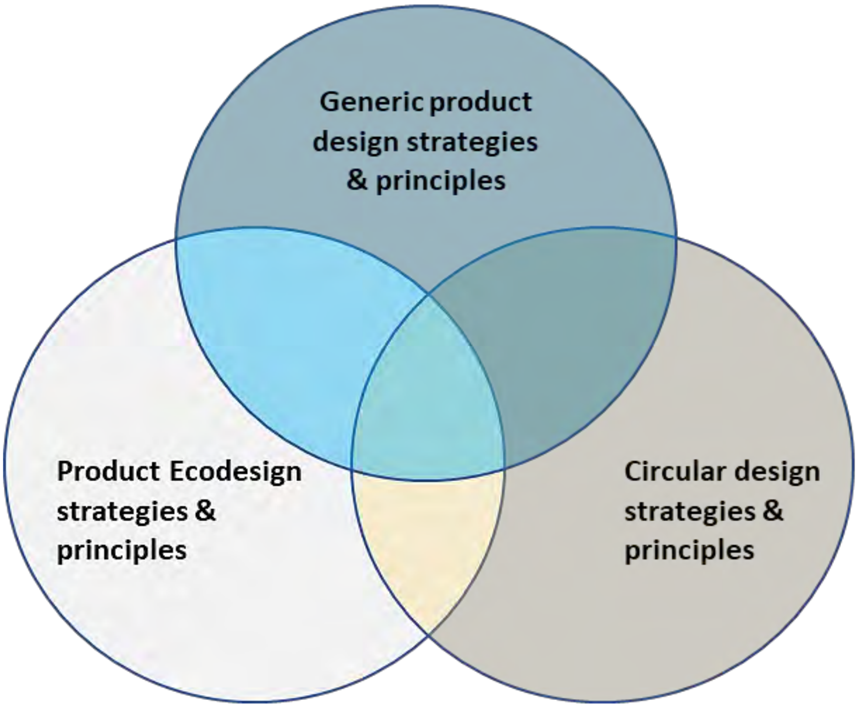

**Figure 1. Schematic of the categorised product eco-design, general design, and circular design strategies and principles.**

strategies and principles when designing long-lasting metal products.

*Adoption and adaptation of existing traditional mechanical design and product eco-design strategies, principles, and guidelines into circular product design strategies, principles, and guidelines for the metal sector*

Since circular design is a recent idea in the evolution of design, it encompasses several aspects of other types of design approaches including eco-design and its design strategies and principles as indicated in Figure 1. Nonetheless, circular design has its unique distinction from other types of design as it takes the ideal approach of eliminating waste through the superior design of materials, products, and systems (Ellen MacArthur Foundation, 2013). Thus, the characteristics or traits that promotes material circularity must be present in all chosen and modified product eco-design strategies, principles, and guidelines. For instance, a design strategy, principle, or guideline for product design that advocates decomposition cannot be seen as one that fosters the circular flow of metal resources. Hence, all the relevant aspects that foster waste, short product lifespan, undesired or early obsolescence, have been eliminated.

*Systematisation of Circular Product Design Strategies, Principles, and Guidelines for the metal sector*:

The systematisation of CPDSs, CPDPs, CPDGs includes the development of a hierarchical structure of the Circular Design Strategy Wheel which is derived from the Eco-design Strategy Wheel (White, Belletire, and St. Pierre, 2013; Brezet and van Hemel, 1997). It has been used as the model for the development of the Circular Design Strategy Wheel because it is a product design tool that provides a logical or systematic approach to address product design issues. It presents product design knowledge in a simple format with various levels of detailed product design strategies, principles, and guidelines which span the entire product design lifecycle phases. Product eco-design is also the design framework that shares the most common and comprehensive product design strategies, principles, and guidelines with circular product design. Those that are not common between the two design frameworks are easily adapted to CPDSs, CPDPs, and CPDGs. As such, the Eco-design Strategy Wheel represents the best available model to develop the Circular Design Strategy Wheel. To fulfil the aim of achieving full metal circularity, three approaches; slowing, narrowing, and closing material resource loop were adopted by the CircularMetal research programme. They were combined with the research programme's aim, CPDSs, CPDPs, and CPDGs to create the Circular Product Design Pyramid (Figure 4).

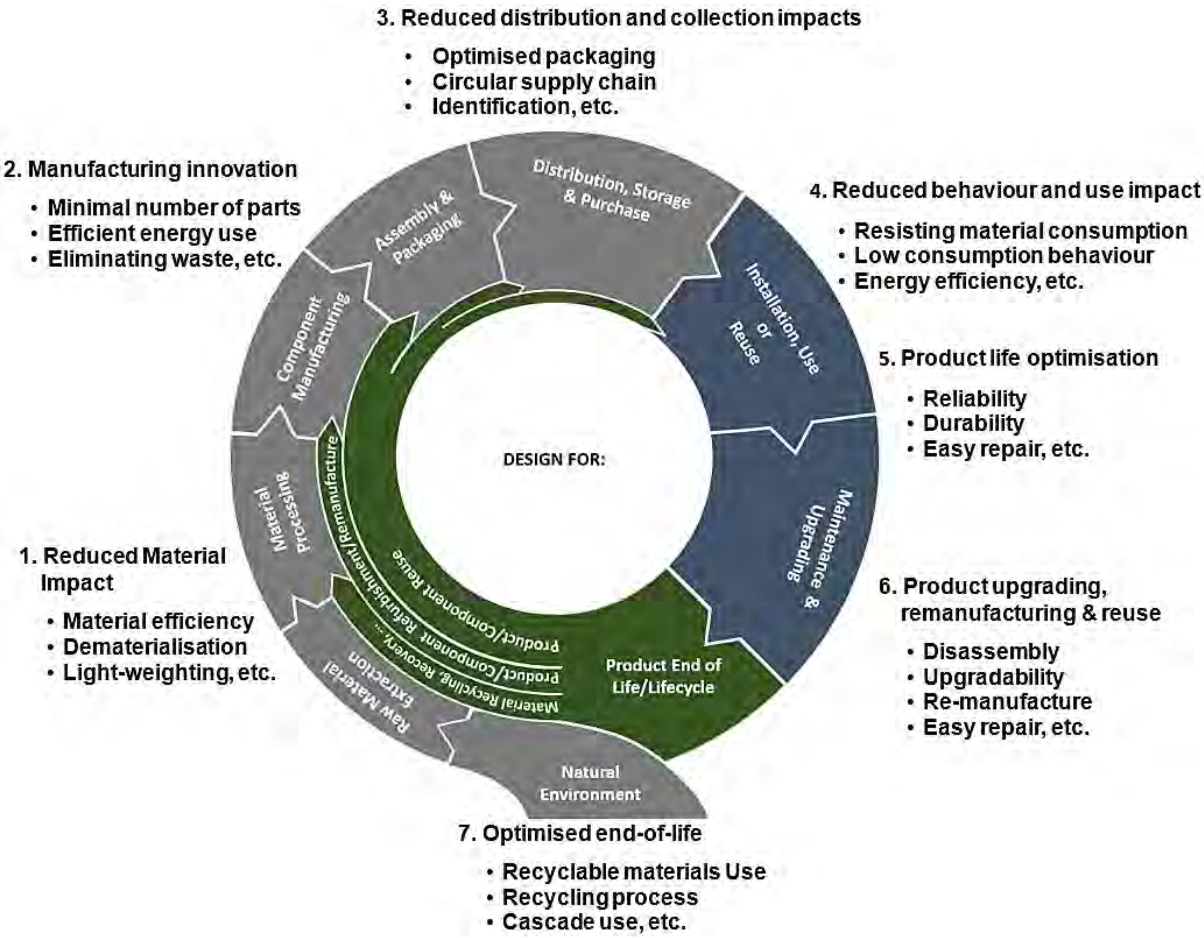

**Figure 2. Circular Design Strategy Wheel with examples of circular product design strategies and principles. Adapted from Eco-design Strategy Wheel (White, Belletire, & St. Pierre, 2013; Brezet & C. van Hemel, 1997).**

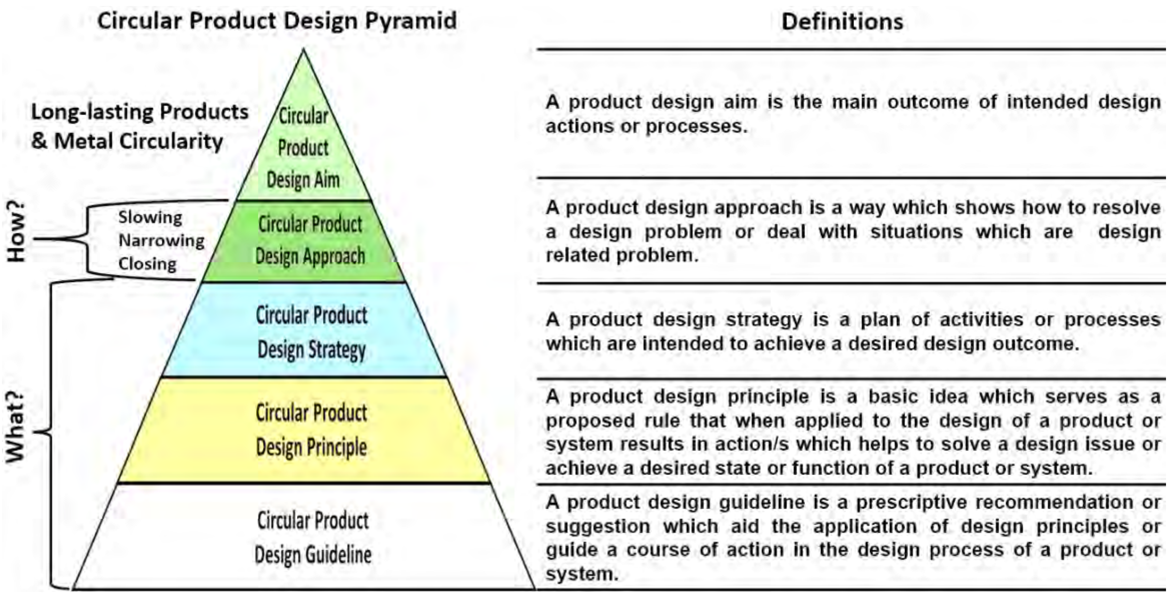

**Figure 3. The circular product design pyramid with definitions (right) of its various constituent design elements.**

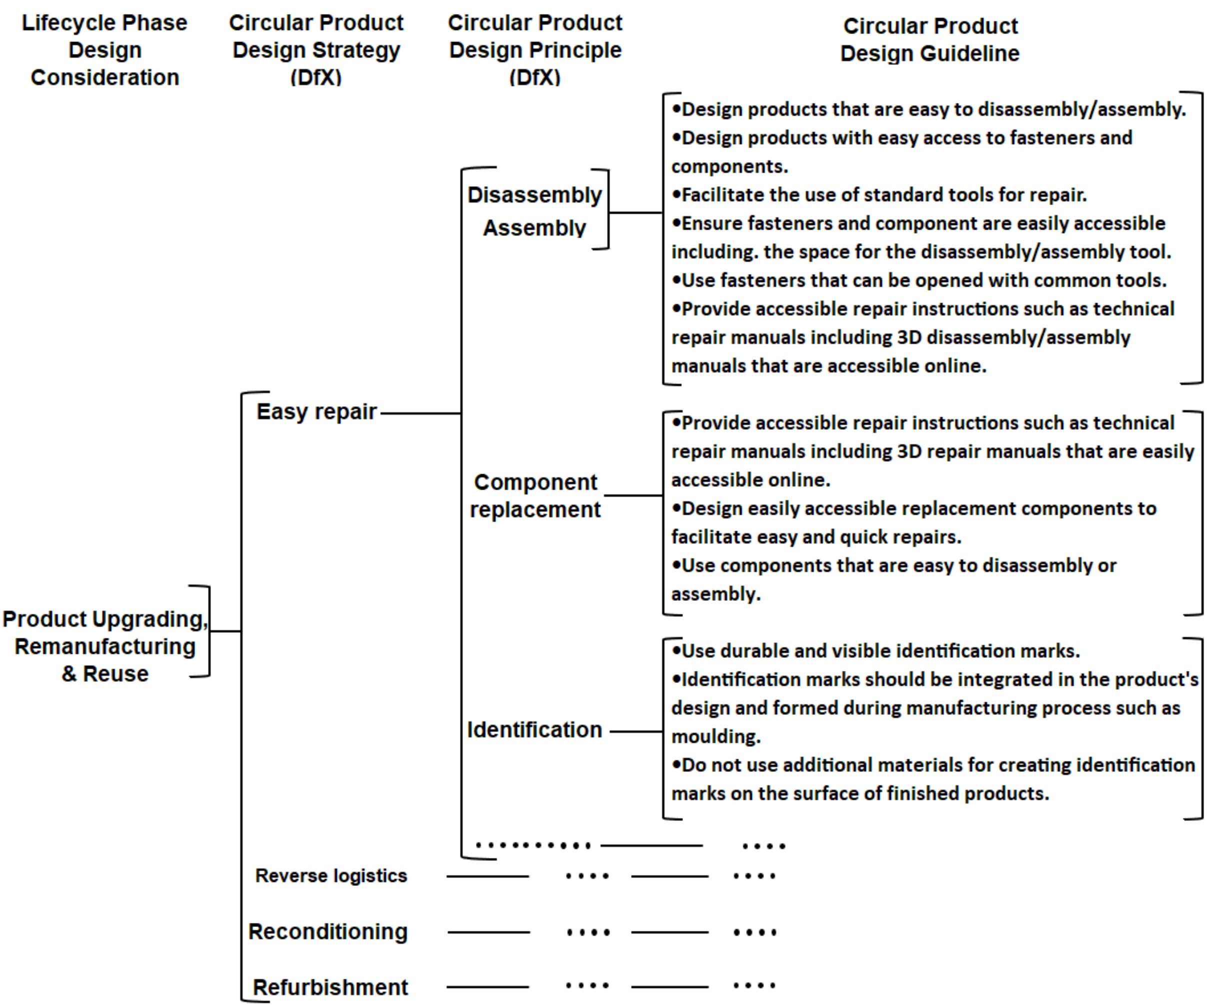

**Figure 4. An example of a tree diagram of the various levels of the circular design strategy wheel.**

## Results

The work done in this study resulted in the systematisation of clearly defined and comprehensive circular product design strategies, circular product design principles, and circular product design guidelines. As part of the Circular Design Strategy Wheel, they form the most import aspect of the current study. They were defined from the adoption and adaptation of the existing traditional mechanical design and product eco-design strategies, principles, and guidelines. Those which were adopted possess inherent circular product design characteristics. The ones that have been adapted lack circular product design characteristics completely or in part, e.g., minimise manufacturing waste is adapted to design for eliminating manufacturing waste. This adaptation aligns with the focus of metal circularity which is concerned with eliminating waste instead of minimising it. Also, new CPDSs, CPDPs, and CPDGs were also integrated into their respective categories and proposed specifically for the metal sector. The product design guidelines are comprehensive and span over the different lifecycle stages. They include aspects such as metal manufacturing processes, new and developing technologies, robotics, artificial intelligence, and other processes which enable the design of long-lasting metal products and circular flow of metal resources.

There are currently 32 CPDSs, 46 CPDPs, and 161 CPDGs. Some of the CPDGs also consist of a total of 277 detailed recommendations which are called circular product design guideline considerations. They enable the easy application of the relevant CPDGs which require multiple product design considerations to support the implementation of CPDSs and CPDPs in circular product design. The results also include the definitions which are given for product design strategies, principles, and guidelines to make a clear distinction among these terminologies which in the literature are sometimes used indistinctly. The distinction among these terminologies serves the purpose of eliminating any form of ambiguity when they are used in the context of product design.

Furthermore, the work undertaken resulted in the development of the Product Design Terminology Classification and Identification Matrix which is used to classify the circular design strategies and principles into their respective categories. It is also used to identify CPDSs and CPDPs which are related to each other. The identification of relationship between CPDSs and CPDPs is made possible by matching their relevant attribute. The related CPDSs and CPDPs can be sub-design strategies of a higher-level product design strategy, and sub-design principles of higher-level product design principle. As such, the Product Design Terminology Classification and Identification Matrix enable the formation of a detailed tree diagram hierarchy (Figure 4) which reflects the various levels of the Circular Design Strategy Wheel (Figure 2). The Circular Product Design Pyramid (Figure 4) was also created as tool to show the various levels of hierarchy of the CPDSs, CPDPs, and CPDGs.

## Discussion and Conclusions

### *Potential Benefits for Designers to use the Framework and related Strategies, Principles and Guidelines*

There are potential benefits that can be derived from using the Circular Design Strategy Wheel with its associated CPDSs, CPDPs, and CPDGs. They may be considered significant, primarily the positive impact on the environment and the availability of metal resources for future generations. Designers or the metal sector can utilise this framework to design long-lasting metal products of different types of metals. This framework and its related CPDSs, CPDPs, and CPDGs not only addresses present product design challenges for the metal sector, but also future ones. They encompass the entire product lifecycle phases and include aspects such as artificial intelligence, robotics, new and developing technologies and metal manufacturing processes. Its wide scope and framework allowed for its further development to include new CPDSs, CPDPs, and CPDGs in line with technological advancement and metal product innovations of the future. It should be noted that there is the potential to include more CPDSs, CPDPs, and CPDGs as this research project continues. The Product Design Terminology Classification and Identification Matrix will also enable the further development of the Circular Design Strategy Wheel with the addition of new CPDSs, CPDPs, and CPDGs.

### *Summary of achievements*

It must be noted that outcome of the various CPDSs, CPDPs, and CPDGs can produce contrasting results. For example, lightweight designs might not be durable enough for product longevity as the reduced material input affects structural stiffness and reduced loading cycle. However, there are CPDGs that suggests the use of ribbed designs to increase the strength of lightweight metal components or products for long-lasting use. Also, guidelines that deals with material selection including the use of multi-principal element alloys enable the design of long-lasting metal products that fosters circular flow of metal resources. As such, the application or purpose for which the metal product is design for will determine the appropriate trade-offs that can be made or accepted by the product designer and product user respectively. The trade-offs also will also affect the longevity of the metal products. Nonetheless, the inherent circular product design characteristics will certainly enable the circular flow of metal resources if the CPDSs, CPDPs, and CPDGs are implemented in the design of the long-lasting metal products and in the right conditions of a CE. Designing long-lasting products does not necessarily guarantee circular flow of materials as there are other external factors such as human behaviour that can influence circularity of metal resources.

The perceived or actual value of the CDSW and its CPDSs, CPDPs, and CPDGs for the metal sector cannot be used to determine its adoption by design practitioners in both industry and academia. The reasons for any undesired lack of adoption by practitioners may not be associated with its practical usefulness in the design of long-lasting metal products or circular flow of metal resources. But, it may be due to reasons that hinders the adoption of eco-design including logistics information and supply chain issues (Eijk, 2015), lack of skilled technical workforce (Rizos et al., 2015), high start-up cost (Kirchherr et al., 2018; Eijk, 2015), consumer value preference (Bey, Hauschild, and McAloone, 2013) and business attitude towards change of investment (van Hemel and Cramer, 2002). Therefore, it should not be a surprise if its adoption is not significant in proportion to its value or potential contribution to circular product design.

The Circular Product Design Pyramid illustrates the hierarchical organisation of the CPDS, CPDPs, and CPDGs. It also includes the aim and approaches at the higher levels of the pyramid's hierarchy. This work provides value to both academia and the metal sector. It can be useful to support future research in circular product design and integrated in design tools such as CAD software packages to aid design practitioners design long-lasting metal products that enable circular flow of metal resources.

### *Next Research Steps*
Further work is required to be done including the validation of the Circular Design Strategy Wheel, CPDSs, CPDPs, and CPDGs. Other work includes the integration with circular business model archetypes which are developed in another stream of this research project. These will be applied to three case studies in the metal sector. Practitioners and the metal sector will benefit from such through knowledge gained in experiencing the use of Circular Design Strategy Wheel to design long-lasting metal products.

## Acknowledgments
The research project is part of the CircularMetal Research programme with fund from UKRI and part of the National Interdisciplinary Circular Economy Research programme (NICER). The experts and support staff who kindly contributed their time and expertise to this study are acknowledged by the authors with sincere gratitude.

b) Independent researcher, St.Petersburg, Russia
c) University of Turku, Turku, Finland
d) ITMO University, St.Petersburg, Russia

**Keywords**: Circular economy; Behavior change; Circular skills; Digital solutions; Social learning theory.

**Abstract**: The circular economy (CE) vision assumes that consumers will be increasingly turning into users of circular services, enabled by various digital solutions. Thus, the role of digital technology is key in supporting circular consumption patterns. The purpose of our study is to examine the practical everyday challenges faced by individuals active in the CE in the context of new digital solutions needed for facilitating circular lifestyles. Drawing on semi-structured interviews (40) with eco-influencers and eco-activists from across different cities in Finland and from the city of St.Petersburg (Russia) conducted in 2021, we reflect on the skills required for participating in the CE, and discuss the challenges of acquisition and diffusion of new circular consumption patterns. These are, for instance, related to learning about materials qualities, their application and safety for repurposing, and distinguishing between new packaging materials for correct recycling. We complement the literature on circular consumption with insights on digitalization in the CE and the social learning theory to scrutinize how digital solutions could facilitate more circular consumption. Our findings confirm that existing digital solutions for circularity help to structure information, improve transparency related to product's location and facilitate recognition of materials for sorting waste. Yet they are designed for consumers as independent individuals, mostly interested in self gain. Our results, on the contrary, suggest the need for digital solutions to reinforce existing social relations and serve as enabling tools for neighbourhood-based approaches of reusing, sharing, renting and recycling together with close circles of friends, relatives or neighbours.

## Introduction

The circular economy (CE) has been recognized by the European Union and many other countries, including China, USA and Russia, as one of the key solutions for achieving more sustainable development (Merli et al., 2018). Recently, more individuals worldwide have started to get interested in repairing, reusing and donating good quality, but no longer needed things. In this sense, digitalization is an important enabler of circularity on consumer level because it improves transparency related to product's location, condition and availability (Antikainen et al., 2018). While CE studies increasingly discuss the role of digitalization in driving the development of circular businesses (e.g. Ranta et al., 2021; Nham, 2022), limited attention has been paid to the potential of digital solutions in facilitating consumer circularity in everyday life. Yet, scholars also point out that while apps can help to connect, inform and educate consumers on circularity, the app market is overwhelming (Hedberg & Šipka, 2021). The purpose of our study is to examine the practical everyday challenges faced by individuals active in the CE in the context of existing and new digital solutions aimed at improving circularity. We analyze the circular experiences of eco-activists and eco-influencers from Finland and the city of St.Petersburg (Russia) to highlight the need to better embed elements of social learning into existing digital solutions for circularity. In our study, we draw on circular consumption literature, combined with insights on digitalization, gamification and social learning theory for discussing how to facilitate the transition to more circular lifestyles among consumers.

## Literature background

### *Circular consumption and digitalization*

Many everyday behaviours have a routine character, without the rational deliberation, making it difficult to sensitize consumers to the new ways of behaving (Jackson, 2005). In fact, it has been suggested that consumer habits formed by linear business models are a strong barrier to adopting more circular patterns of consumption, e.g. leasing instead of ownership (Parajuly et al., 2020). Moreover, engaging in reuse of goods implies being active in second-hand markets, where interactions between buyers and sellers are less scripted than in regular stores, often requiring skills related to carefully judging the quality of items, negotiating and building relationships with buyers or sellers for future purchases (Crewe & Gregson, 1998). According to Wieser (2019), participation in the CE actually involves a high degree of skill and creativity from citizens, and in addition to acquiring new skills, there is work associated with unlearning the non-circular consumption habits. The pressures related to lack of time, limited cognitive resources in combination with the hurried lifestyles all make it challenging for consumers to reconsider and switch to the new ways of consumption.

An important element for changing everyday behaviour is the "unfreezing" phase, which requires being aware of the need to change, considering the alternatives (and seeking information about them), as well as evaluating the pros and cons of the new behaviour (Dahlstrand & Biel, 1997). In this context, digital tools have the potential to facilitate the unfreezing with gamification approaches by offering structured information about the alternatives, introducing goals or reward points for circular behaviours, and by creating interaction with peers, family or friends around the circular lifestyles. A recent study from the Finnish settings on gamification in the context of recycling confirmed it to be an efficient tool for supporting a change in the recycling behaviour (Santti et al., 2020). Yet, scholars admit that policies and investments have been too slow to encourage purpose-driven development of digitalization for the CE (Hedberg & Šipka, 2021). While the abundance of apps of today is overwhelming to consumers, guidance from important players like city administration could really help to encourage more active use of the digital solutions for CE.

### *Social learning theory*

As humans are social creatures, learning by example has been recognized as one of the key factors in establishing behavioural patterns (Jackson, 2005). This is the foundation of social learning theory (Bandura, 1977), which suggests that people tend to learn from examples of how others behave, especially if these others are important to us, attractive, or we identify with them. For instance, the research on environmental education suggests that influence of known adults (e.g. parents or teachers) tends to foster environmentally responsible behaviour among children more effectively compared to more distant adults, like celebrities (Stern et al., 2018). A study on the use of public compost bins corroborated that also adults learn vicariously, by observing others and people in their social networks (Sussman & Gifford, 2013). In general, while information provision alone is often insufficient, conveying it through modeling (the behaviours of others) or complementing information with insights on how others behave (especially in close circles, e.g. neighbours) tends to be more effective (Abrahamse & Matthies, 2018). Earlier studies also found that providing frequent feedback encourages and supports pro-environmental behavioural change (Abrahamse et al., 2007).

## Materials and methods

For the purpose of exploring the experiences of the citizens that actively practice circular ways of consumption, we conducted qualitative semi-structured interviews (40) in two national settings. The first one - Finland - represents the CE of developed settings, where circular practices like recycling have been institutionalized in society for many years. The second setting - city of St.Petersburg (Russia) - is more representative of the CE from the emerging economy countries, where many circular practices are informal. In Finland, the age range of interviewees varied between 25-76 years old, including 13 women and 7 men. In St.Petersburg, the age varied between 24-41, including 16 women and 4 men. Most interviewees identified themselves as eco-activists or eco-influencers. The search for first interviewees took place via local environmental organizations, like Zero Waste Finland or Trash-No-More ("Musora Bolshe Net") in St.Petersburg, with subsequent snowballing for identifying and recruiting next interviewees.

All interviews were recorded and transcribed in the language of the country. The data was coded using Atlas.ti software. Thematic analysis was guided by a grounded theory approach, with inductive coding and emphasis on circular practices, associated challenges and skills required for performing the practices, as well as digital or online solutions. The emerging codes were assigned in English to both datasets, with subsequent translation of the relevant interview parts into English. Comparative analysis was conducted through reiterative discussions between the members of the two country teams.

## Results

Previously scholars emphasized that consumer lack of interest in circularity is among the main barriers to CE implementation (Kirchherr et al., 2018). Our findings illustrate that switching to the new, more circular consumption patterns is challenging due to the time, effort and special skills necessary for participating in the CE. Some of these are related to the "unfreezing" phase of transitioning from old to new forms of consumption, and to acquiring new skills (e.g., Wieser, 2019). Our findings further specify that the circular consumption is often compromised by: 1) lack of circular information; 2) lack of structured information; 3) lack of circular infrastructure and services. While there exist a number of digital solutions aimed at helping to address these challenges, their use is still limited and they often prove to be sub-optimal. Table 1 provides examples of existing digital solutions, the consumption work or challenges they are supposed to address (Appendix).

### *Lack of circular information*

One might claim that today it is easy to find any information online, but, in fact, the circular information concerning durability, repairability, recyclability is often difficult to grasp or even missing. For instance, our interviewees mentioned having to conduct their own research regarding the sustainable ways of consumption, as online resources sometimes provide conflicting or confusing information. Many activities get labeled under "circular economy", even if they might refer to incineration instead of other value retention options that keep materials in circulation for longer. Moreover, due to rapid emergence of products and packaging labeled as "bio" (e.g. biodegradable plastic, bioplastics, etc.), the correct sorting of waste becomes complicated. The feel and outlook of products might be misleading (e.g. cardboard take-away cups with plastic coating), but learning from others helps:

*"For beginners, it is difficult at first and takes time to get used to. It makes life much easier to learn from someone else's positive experience, to read short instructions. In my case, the training took place in the process of volunteering. After three campaigns, I was already familiar with the types of recyclables, I understood what could be handed over and what not "* (interview 18, St.Petersburg).

Also, repurposing materials requires knowledge about the properties of the materials, their safety and suitability for the new purpose. Plastic is a good example of a durable material, which comes in many varieties. Yet, not all plastic-like materials are suitable for reuse, and some might be dangerous to health.

*"...many people make bracelets or rings, or jewelry made from old electrical wires. After all, the electrical cords are really nicely colored, so you can make anything from them. But in my blog post I explain that they contain the plastic softener phthalates, which is also in the VHS tapes. That phthalate is a hormone disruptor, and if you wear this phthalate jewelry 24/7, like I once wore it on my bracelet, then it might be together with all other things that we get from the environment, it disrupts your body's hormonal activity*" (interview 16, Finland).

As evident from the examples above, circular information necessary for recycling and repurposing is not easily available. Often it requires time or even special education and training to start recognizing the waste fractions and materials suitable for repurposing. Even in Finland, where recycling has been institutionalized in society for a long time, the newly emerging packaging materials pose a challenge for waste sorting. Digital solutions for facilitating recycling just entered Finland recently (in 2022), while repurposing of materials has not received as much attention.

### *Lack of structured information*

Shopping second-hand in online market places may seem like a convenient solution, but in many instances our interviewees pointed out that it requires skills related to communication, because product descriptions are often incomplete or misleading. Browsing the online market places is challenging: the search results produce too many hits and search tools of existing digital solutions require development. In case of furniture or other larger items, one might have to "hunt" for these for many months.

"*.. it's challenging to look for something specific in the flea market. Some brick and mortar flea store usually offers only a very limited selection. For example, online marketplace tori.fi has a huge selection, but there again the challenge is how to find what you need from the huge selection there. Of course, those search functions are definitely being developed all the time, but then from the search results there always comes something that you weren't even looking for, so it doesn't necessarily work.*." (interview 7, Finland).

In addition to the established digital platforms, there exist many social media-based groups (e.g. in Facebook), where it is possible to buy and sell second-hand. These groups tend to be very local, often for the residents of a certain zip code area. The search tools of these groups are not sophisticated, but the convenience of trading locally is higher. In addition, local groups have fewer items on sale, it is easier to scroll through and the users are able to check the profiles of the FB group participants. In the context of St.Petersburg, telegram chats are often in use for the residents of the same apartment buildings or neighbourhoods. These are used for exchanging tips, for instance related to recycling or other residential matters. There are also separate chats for selling second-hand items or giving them away to neighbours. These examples demonstrate how ad-hoc solutions for local residents help to structure information related to circular consumption.

In the Finnish context, interviewees often mentioned their close circles: relatives, friends or neighbours as an enabling network for lending of goods instead of owning everything. Yet, there also seemed to be a need for more structured information on what is available for lending, without having to separately ask or call several persons:

"*I have just suggested to my neighbours that we can make some kind of list, because we have 4 households as part of the cooperative. So we can make a list of things that we own and we can lend to each other, and we would not need to always buy and own*" (interview 5, Finland).

### *Lack of circular infrastructure and services*

Although there were significant differences between the two national contexts related to the availability and types of circular infrastructure and services, the need for more local solutions was unanimous. In the context of St.Petersburg, the recycling points are often located tens of kilometers away from the households, while online resources do not always provide up-to-date information about them:

*"In the beginning, it was difficult to find separate collection points, although it seems that there was already a Recyclemap where you can find places where you can donate recyclables. But it often happened that you came to the point, and it was closed, and it was completely incomprehensible where to carry all these bags"* (interview 7, St.Petersburg).

In the Finnish context, there emerged a wish for having local lending centers, instead of just renting services. Although peer sharing platforms for different household items exist, if one is in need of renting several items (e.g., for camping), it may be that they have to be borrowed from different users in different locations. Picking them up without a car is difficult, and there is a need for services optimizing the logistics of lending or renting services.

## Discussion and conclusions

While circular consumption involves degrees of competence, skills and creativity, the research into how these may be acquired and diffused in the society has been scarce (Hobson et al., 2021). In this connection, our findings bring forth the importance of one's social relations (existing social networks) for acquiring and reinforcing circular consumption patterns, and the need for neighbourhood-based approaches in diffusing circularity.

Existing digital solutions for circular consumption patterns are designed for consumers as individuals, acting independently and in self-interest. Our data, on the contrary, highlights how citizens come up with ad-hoc solutions using social media platforms and messengers to create smaller local communities around their efforts to implement circularity.

We propose that there is a need to develop (or tailor) digital solutions for already existing circular practices in communities, better serving the networks of citizens who are connected for reasons of friendships, family or neighbourhood relations. Digital solutions have the potential to make circular patterns of consumption more visible in a circle of friends, relatives or neighbours by providing data on user activities, or by making their sharing/renting offers visible. This enables possibilities for vicarious learning (Bandura, 1977) in a discrete manner for acquisition of the circular habits. Also, it could facilitate sharing or renting in the social circles where the degree of trust towards each other is higher than with strangers, helping to overcome the old linear economy habits as described by Parajuly et al. (2020).

Finally, while Hedberg & Šipka (2021) point out that the app market can be confusing and overwhelming, we suggest that in line with the social learning theory, government has an important role in modeling and directing the circular behavior, which applies to digital solutions too. For instance, recycling and repurposing, which have important implications for waste recovery and safety, could benefit from clear guidance and a designated digital tool developed and promoted by the municipality, much like apps for the use of public transport available in many different national contexts.

To conclude, we emphasize that the existing digital solutions have been very important in supporting the circular practices described by the interviewees, e.g.by means of geolocation, more structured and tailored information. However, in the circumstances of high information loads, new emerging materials and practices related to consumption, our interviewees from both contexts referred to important examples of others in their close circles, learning by doing together with peers, and trying to form circular circles within their own neighbourhood. Thus, it is important that digital solutions are able to reinforce these needs for social learning from close peers, instead of focusing on consumers as independent individuals in search of gain.

# How can repair businesses improve their service? Consumer perspective on operational aspects of repair services

**Verena Kraßnig, Gernot Lechner, Ines Güsser-Fachbach**
Department of Operations and Information Systems, University of Graz, Graz, Austria

**Keywords**: Repair service; Operations; Consumer survey; Importance.

**Abstract**: Repairing broken products is not yet preferred over replacing these items with new goods. One major issue is that repair is typically perceived as being too expensive, time-consuming and cumbersome. In order to change consumption habits of consumers and thus, to increase repair rates, repair must be an attractive option, i.e., in comparison to purchasing new products. For achieving this, repair businesses must offer convenient services and continuously improve their processes. Our study aims at identifying the most important aspects for (potential) consumers of repair services. First, based on an extensive literature review which is complemented by expert interviews, operational aspects were compiled. Thereafter, the importance of these aspects from the perspective of consumers was determined through a survey study with more than 600 participants. We find that the most important items are related to information and economic aspects, and moreover trust-building measures and communication skills. The comparison of item importance related to various product options indicates that the results are a general representation of the importance of operational aspects independent from the specific product. The results of this study support repair businesses to streamline their services, and on the other hand policy-makers can identify promising entry points for effective policy measures fostering repair.

## Introduction

Although various initiatives are promoting the transition to a circular economy, the "take - make - waste" paradigm is not over yet. Repair is crucial to this transition, as it allows for a longer useful life and is therefore generally less harmful to the environment than buying new products. To increase repair rates, consumers must be willing to change their usage habits and initiate repair activities to extend the life of their products (Ackermann et al., 2018). Albeit research has shown that, for example, cost and time are important economic aspects for consumers' intention to initiate product repair (Fachbach et al., 2022), these considerations mainly focus on the strategic/tactical level of repair services. To date, there is a lack of evidence on customer preferences regarding the attributes of repair services at the operational level. In particular, the question arises: *what are the most important operational aspects from a consumer perspective in the context of repair services?*

We see operational aspects as factors impacting the repair service process which can be controlled and adapted by the repair business in the short-term. Thus, this excludes tactical/strategic decisions like the choice of location or whether to offer repair services at all in the design of the product / service portfolio. Instead, operational factors were derived from literature or interviews: for instance, customers need to obtain the relevant information to attain the full value of a product or service (Lovelock and Yip, 1996). Based on an example of a woman who experienced an excellent repair service covering the repair of the broken product as well as an explanation of what had failed and how she could repair it by herself (cf. Parasuraman et al., 1985), we created two items: "*The employee explains what needs to be repaired and why.*" and "*The suggestions of the employees help to avoid mistakes using the repaired product in the future.*". Both of these potential interventions are (rather quickly) viable in repair businesses.

## Research approach, method and data

To investigate operational factors of repair services, we follow a three-step approach, whereof the third one is future work and not included in this article. As can be seen in Figure 1, at first an extensive literature review identifies specific operational aspects that can be influenced by the repair company at three different stages of the repair process, which are the prepurchase, service encounter, and post-encounter stage (Wirtz & Lovelock, 2021). Expert interviews complement these findings with practical insights and allow validation of theoretical findings. Corresponding aspects are, for example, "If necessary, a loaner unit is provided for the duration of the repair" or "Only original spare parts are used for the repair." In case that some aspects can be assigned to several stages, we opted for including it in the prepurchase stage, as it represents the customers' most important decision whether to repair or not. Secondly, the aspects identified for potential improvement of the repair operation are included in a survey to ascertain the importance of these points as perceived by customers on a 7-point Likert scale (extremely important to not at all important). The survey considers the scenario that repairs are conducted at a repair service center but not as a repair service at home as, e.g., for washing machines. This facilitated to split the sample into four groups, each of it referring to a different portable product to be repaired (bicycle, smartphone, vacuum cleaner and a general product), in order to examine the generalizability of the results. Third, as future work, we plan to apply an Analytic Hierarchy Process to obtain a prioritization of these aspects by pairwise comparison. For this purpose, we create a multi-level categorization scheme and evaluate the most important operational aspects per predefined category.
The survey was conducted in Austria with the objective to obtain a representative sample in terms of age, gender, and education level: 620 fully completed questionnaires were returned, whereof 150 were excluded: either the time for filling the questionnaire was extremely short (less than five minutes), or the included control questions were answered wrongly. The final number of 470 survey participants was the basis for the results.

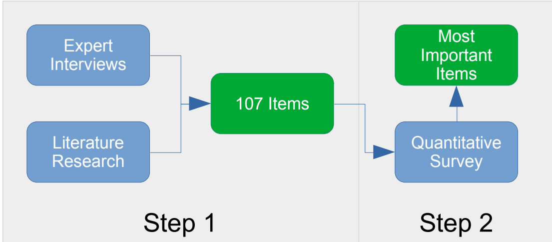

**Figure 1. Research design of the study.**

## Results

In the first step, we identified 107 aspects to be considered in the context of repair services: 63 in the prepurchase stage, 24 in service encounter stage, and 20 in the post-encounter stage. These aspects include, for example, communication-/convenience-related or technical statements, but also concerning business operations, or expertise and social skills. In the following, we focus on two major results of the preliminary analysis: first, the identified most/least important items, and second, the potential generalizability of the results.

### *Importance of operational aspects of repair services*

The results base on mean / median values for each of the 107 items, jointly considered in box plots in Figure 2a and 2b. This overview of mean and median values emphasizes that most of them were considered as important. This is in line with the authors' expectations as the study was designed to identify the most important items, thereby including aspects that were considered as potentially being important. Nevertheless, a closer look reveals more nuanced results: first, although both median values of the box plots are at (about) two, the values concerning of the first / third quartile differ recognizably: while in Figure 2b 75% of the median are less or equal than two, the third quartile in Figure 2a is at about 2.5. In addition, the number of outliers is greater in the case of mean values: Figure 2c reveals that six items with a distinct higher mean value (and thus, lower importance) exist. The mean importance of the remaining items increases rather steadily.

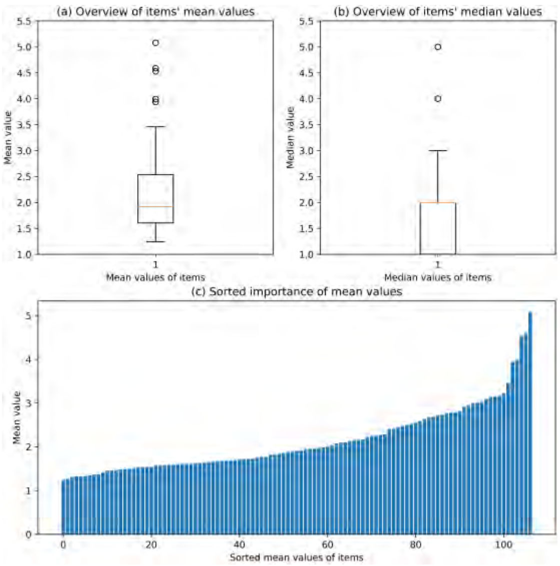

**Figure 2. Overview of mean/median values.**

In Table 1 we present the top 10 of the most important items. It is obvious that all of these are rated as being eminently important for customers. Though, the operational aspects ranked at 1, 2, 4, 5, 7, 8, 9 are related to information provided to the customer and / or economic aspects. Others concern communication (10) or trust (3, 6).

| Item | Mean |
|---|---|
| As a customer, you receive sufficient information about the costs incurred for the repair. | 1.24 |
| Employees provide customers honest information about whether the repair is still worthwhile. | 1.27 |
| Employees appear to be technically experienced and know more than their customers. | 1.31 |
| In the event that a problem arises during the repair, the customer is informed immediately. | 1.32 |
| In the event of inadequate repair or other misconduct, customers are reimbursed according to the damage. | 1.32 |
| Products entrusted to the repair facility will be kept safe and not damaged. | 1.33 |
| Employees keep promises regarding repair costs. | 1.34 |
| The consultation at the repair facility provides all necessary information. | 1.37 |
| Customers feel they have paid a reasonable price for the repair. | 1.37 |
| The employees express themselves in an understandable manner. | 1.41 |

**Table 1. Most important items – Top 10.**

The top 10 of the least important items are listed in Table 2. Notably, the three least important items concern different types of communication channels, while reaching employees through phone is not in this table.

| Item | Mean |
|---|---|
| Employees can be reached via social media. | 5.08 |
| Employees can be reached via messenger services. | 4.59 |
| The employees can be reached via SMS. | 4.53 |
| In exceptional cases, the repair store is available outside regular opening hours. | 3.99 |
| The website provides comprehensive information about the history of the repair store. | 3.94 |
| Only original spare parts are used. | 3.46 |
| The repair store has been personally recommended to you. | 3.22 |
| When visiting the repair shop, everyone is busy and dedicated to their work. | 3.16 |
| The repair company aims to employ men and women equally. | 3.15 |
| The repair store offers a pick-up service for the broken product. | 3.14 |

**Table 2. Least important items – Top 10.**

### *Generalizability of the results*

The randomly assigned product options (smartphone/bike/vacuum cleaner/portable object) resulted in four groups consisting of 110/111/118/131 surveys. We applied the Kruskal-Wallis test and compared the items pairwise to test differences concerning the mean value of individual items. Out of the 107 items, only four showed significant pair-wise differences. For instance, "*The repair company is certified or has a service partnership with well-known brands.*" is perceived as significantly more important for smartphones than for bikes, and "*Only original spare parts are used.*" is also considered as being more important for smartphones than for a general product or vacuum cleaners.

## Discussion

Due to the nature of the study design, most of the items were perceived as reasonably important for customers. Typically, literature addresses economic aspects as the most relevant ones (cf. Bovea et al., 2018; Güsser-Fachbach et al., 2023). Of course, this is also reflected by the most important items, but we identified information provided to customers as another main category for operational aspects. Even though this was mentioned in literature (see, e.g., Huang and Dubinsky, 2014; Lovelock and Yip, 1996), economic factors have been much more pronounced so far. In line with the state-of-the-art of research, communication skills (Cronin et al., 2000) and trust-building measures (Ma and Osiyevskyy, 2017; Riisgaard et al., 2016) complement the top 10-items. Summarizing these insights we determine that customers (1) require the information about costs and economic viability of repair; (2) appreciate a trustworthy repair process with skilled employees; (3) have a strong aversion to nasty surprises like change in cost or issues concerning repair without prenotification. All of these requirements should be communicated in an understandable way.

The least important items focus on communication channels. Interestingly, although social media is regularly used in the context of circular economy (Tsironis et al., 2022), our results support past findings that such platforms play a minor role for the success of repair businesses (e.g., Fachbach et al., 2022). Yet, the results show that regarding communication with repair experts phoning is still the preferred method. Thus, repair businesses need to distinguish between various capabilities of communication channels, i.e., interpersonal communication and advertisement.

Concerning access convenience we observe an interesting result which complements existing knowledge (e.g., Güsser-Fachbach et al., 2023a): while it is important for customers that they can initiate a repair off the job, there is no need to provide excessive flexibility through the option of being available outside the regular store hours. A further insight contrasting current research is the rather low level of importance of personal recommendation. In previous works such peer recommendation was determined as being highly relevant for customers (cf. Fachbach et al., 2022).

Finally, the non-required usage of original spare parts draws our attention: even though it is considered as being less important than other items, this aspect is significantly more important for smartphones. Hence, we hypothesize that (1) people who get something mended prefer in general the recovery of functionality over brands, but (2) this does not hold true for fashion-related products like smartphones.

## Conclusions

Although the wealth of possible aspects for repair operations cannot be summarized in a single study, we show that operational aspects complement the decisions and influencing factors at tactical and strategic level. The quantification of the importance of individual operational aspects creates a clear picture of what aspects to focus on to increase the attractiveness of repair services.

The consistently high level of importance demonstrates the complexity of repair, as many aspects need to be considered in repair operations. As items related to economic aspects, information, communication, and trust-related measures are top-ranked, these are starting points to improve repair businesses. Additionally, the newly identified operational aspects help to expand future theories of repair services.

Even though the intra-group comparison—smartphone, bicycle, vacuum cleaner, and general product—of four items show distinct significant differences, there is a strong indication that the results of this study are independent from the product. Thus, we conclude that the insights can be transferred to other repair contexts and sectors.

Concerning future work, we expect the planned survey based on the analytic hierachy process to provide an even clearer picture of repair customers' priorities. In particular, based on the pairwise comparison we want to answer which of the selected aspects play a decisive role in which phase of the repair process. The ranking of the aspects will ultimately allow to provide guidance for repair businesses on how to improve repair operations according to the priorities of the customers, and thus, how to sustain an effective repair business. In addition, further analyses based on the gathered data—e.g., exploratory factor analysis or clustering of items—might reveal further data structures relevant for repair. Finally, to elaborate on the conditions when to use original / replicated spare parts seems to be a research topic worthwhile to consider, as this might have a huge impact on the profitability of repair.

# The weakest link: how technical lifespan extension can be counter-effective for climate goals

**Kamila Krych[a], Johan B. Pettersen[a]**
a) Norwegian University of Science and Technology, Trondheim, Norway

**Keywords**: Kitchen; Relative obsolescence; Material flow analysis; Life cycle assessment; Rebound effect.

**Abstract**: Numerous studies have shown that service lifespan is lower than technical lifespan because users choose to discard products that are still functioning. Yet, the policy is mostly focused on the extension of technical lifespan, which means that extra resources are invested into ensuring more durable products that can land in waste bins equally fast. This work uses the example of kitchen durables to explore various lifetime extension scenarios and investigate the extent to which these interventions could in fact be counter-effective for climate goals set for 2050. We use material flow analysis to quantify the flows and stocks of appliances and furniture in Norwegian kitchens in 1990-2050. We apply the principle of the weakest link, in which the product is being replaced when it reaches the limit of its technical lifespan or social lifespan. Four lifetime extension scenarios explore various types of obsolescence (relative or absolute) and targeted products (on-the-market or in-use); each scenario assumes the policy implementation in 2025-2030, associated with an environmental penalty. We calculate life cycle impacts over the studied period using life cycle assessment and compare the cumulative emissions of extension scenarios against the baseline, in which no lifespan extension policy is assumed. The results show that design-for-durability policy could increase climate change impacts by up to 6%, which suggests that the current legislative efforts related to product lifetime extension could be counter-effective. The Repair scenario yields the highest net benefits thanks to its focus on in-use products, diverted from waste through repair. We suggest that user- and system-focused policy might yield faster effects and that measures could target particular durables.

## Introduction

Product lifespan is determined by a variety of factors, some resulting from the product's intrinsic properties like the quality of materials, while others result from external factors like social norms, and availability of repair services. This duality corresponds to the concept of absolute and relative obsolescence (Cooper, 2004), product 'nature' and 'nurture' (Cox et al., 2013), or physical (technical) and social lifespan (Klepp et al., 2020), although many similar classifications related to product lifetime and reasons for obsolescence have been used (Packard, 1960; Sheth et al., 1991; Shi et al., 2022; van Nes & Cramer, 2005).

Product lifespan is often limited by non-technical aspects, as illustrated by products being discarded despite still being functional (Box, 1983; Cooper, 2004; DeBell & Dardis, 1979). Although some of these discarded products gain a second life, others end up in the garbage (Curran et al., 2007; Strandbakken & Lavik, 2018), thus not achieving their full lifetime potential dictated by their functional value. Even in the case of technical failure, behavioral and contextual factors can determine if the owner attempts product repair; any kind of repair was attempted in only 30-40% of failed kitchen appliances (Laitala et al., 2021).

Yet, the policy is focused on the extension of the technical durability of products. For example, the EU's legislative efforts are directed towards enhancing product durability and repairability, either through an extension of the Ecodesign Directive (COM/2020/98, 2020) or through a product labeling scheme (2020/2021(INI), 2020). These efforts, although needed, do not incentivize consumers to make the products last, or to repair them. Whenever the limiting factor to lifespan is not technical, any resources invested into more durable and repairable products are wasted resources, given that the products can land in waste bins equally fast. Such technical measures may therefore yield lower than expected resource savings due to behavioral factors, which is known as the rebound effect (Zink & Geyer, 2017); in some cases, the interventions may even lead to backfire – a higher resource use than in a no-intervention scenario.

This work uses the example of kitchen durables to explore various lifetime extension scenarios involving absolute and relative obsolescence and investigate the extent to which these interventions could in fact be counter-effective for climate goals set for 2050.

## The durability of kitchen durables

In the last decades, the way we perceive kitchens has evolved, as described by Shove (2008, p. 22) “No longer a back region devoted to the preparation of food, kitchens are […] represented as places of sociability”. This transition is reflected in the increasingly popular open kitchen layout, where the living room is combined with the kitchen into one large sociable space. As a place of sociability, a kitchen is now more embedded into the social context, making the kitchen looks and the related social lifespan more important. Although no study has investigated whether the frequency of kitchen refurbishment has increased, qualitative research confirms that appearance and adjusting the kitchen to social needs are among the main motivations for kitchen refurbishment (Amilien et al., 2004; Hagejärd et al., 2020; Shove et al., 2008).

The changes in kitchens influence kitchen durables as well. Stoves, dishwashers, and fridges are often physically integrated into cupboards. Although such built-in appliances might sometimes be hidden behind a wooden board, this integrated design strengthens the interdependency between the appliances and kitchen furniture, both co-existing in the kitchen layout. Large kitchen appliances are therefore an integrated part of the furniture, and the furniture’s appearance is ‘extremely important’ (Gnanapragasam et al., 2018). These interdependencies increase the importance of the relative obsolescence of kitchen appliances, traditionally seen as ‘workhorse products’, which are generally valued for their functionality, are most likely to be discarded due to technical failure (Cox et al., 2013; Yamamoto & Murakami, 2021), and are more likely to get repaired (Jaeger-Erben et al., 2021; Laitala et al., 2021).

The relative obsolescence of kitchen durables should not be overlooked; for some appliances, the relative obsolescence is the reason for almost 50% of all discards (Strandbakken & Lavik, 2018). Both absolute and relative obsolescence can be the weakest point and cause discard (Figure 1). Reinforcing one link may mean that another link becomes the weakest one and becomes the limiting factor. In the same way, focusing entirely on absolute obsolescence disregards the importance of relative obsolescence, which would continue to weaken the system.

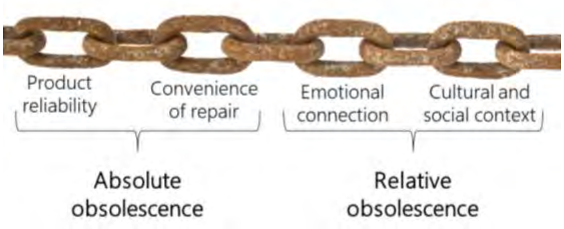

**Figure 1. Product discard can be determined by absolute or relative obsolescence.**

## Methods

Major kitchen durables considered in this work are fridge, dishwasher, stove (oven and hobs), and kitchen cupboards. The flows and stocks of these durables are investigated in Norwegian households during the years 1990-2050 using dynamic material flow analysis (dMFA).

The model is stock-driven, where the stock was calculated by combining the number of dwellings and product ownership per dwelling. The number of dwellings is the population (Statistics Norway, 2023a, 2023b) divided by people per dwelling (Statistics Norway, 1891, 1904, 1913, 1952, 2021). The appliance ownership is taken from the literature (Bøeng et al., 2011; Halvorsen et al., 2005; Lien & Langseth, 2018; Sæbø, 1979; Statistics Norway, 2013), while the ownership of kitchen cupboards is assumed to be the equivalent of 14 standard-sized (60 x 60 x 80 cm) cabinets per dwelling, based on a random sample of 100 dwellings newly announced for sale on February 27, 2023, on a Norwegian website Finn.no. The lifetime was modeled as the Weibull distribution with the shape parameter 2.1 and the scale parameter calculated from average lifetimes: fridges 13.8 years, dishwashers 12.7 years, and stoves 14.1 years (Forti et al., 2018; Prakash et al., 2016; Wieser et al., 2015). The average lifetime of cupboards was assumed as 22 years, based on the number of kitchen cabinets sold in Norway (Braathen, 2015; Falck, 2021).

The climate change impacts per year were calculated using life cycle assessment (LCA), considering the production phase and electricity use during the use phase. The use phase was modeled like in Krych & Pettersen (2021). The impacts were calculated using GWP100 metrics, as given by the IPCC 2021 method (IPCC, 2021). Unit impact scores were sourced from ecoinvent v3.9.1 database (allocation cutoff) (Weidema et al., 2013), and were assumed constant throughout the simulation period.

The baseline scenario (*Baseline*) assumes the continuation of past trends, also regarding the product lifetime. Four alternative scenarios were developed, matching the reasons for obsolescence pictured in Figure 1. All four scenarios assume a policy intervention in the years 2025-2030 intended to extend product lifetime, which comes at a cost of an environmental penalty proportional to the total impacts in 2022 and uniformly spread across the five years. Each scenario assumes a 20% lifetime increase until 2030, but they differ in which products are targeted (on-the-market or in-use), and which type of obsolescence they address (absolute or relative). The share of absolute obsolescence in total obsolescence was assumed as 89% for dishwashers, 57% for stoves, 51% for fridges and 79% for cupboards, which are literature-informed assumptions (Laitala et al., 2021; Strandbakken & Lavik, 2018).

The *Reliability* scenario assumes design efforts focused on the technical reliability of products, which decreases the risk of absolute obsolescence by 20% in all products introduced to the market. The *Connection* scenario assumes design efforts focused on emotional durability and strengthening the product–user connection, which decreases the risk of relative obsolescence by 20% in all products introduced to the market. The *Repair* scenario assumes efforts centered around facilitating repair, e.g., increasing the availability of spare parts and convenience and pricing of repair services, which decreases the risk of absolute obsolescence by 20% in all in-use products. The *Culture* scenario assumes a change in social norms around the disposal of functioning items and frequency of kitchen renovations, which decreases the risk of relative obsolescence by 20% in all in-use products. The scenarios are summarized in Table 1. They are evaluated against each other by comparing their net environmental benefit – the relative difference of the scenario's cumulative climate change impacts compared to the baseline. Here, we consider the cumulative impacts in the years 2025-2050.

**Table 1. Summary of the scenario framework.**

| Scenario | % obsolesc. reduction | Targeted obsolescence | Targeted products |
|---|---|---|---|
| Baseline | 0% | - | - |
| Reliability | 20% | Absolute | On-the-market |
| Connection | 20% | Relative | On-the-market |
| Repair | 20% | Absolute | In-use |
| Culture | 20% | Relative | In-use |

## Results

The climate change impacts in the baseline scenario are dominated by production impacts, which make up 84-89% of the annual impacts in the years 2025-2050. Despite no use-phase impacts, cupboards are durables responsible for the largest share of impacts (Figure 2).

While the baseline climate change impacts develop smoothly after 2025, the alternative scenarios experience an initial impact increase caused by the environmental costs of the policy intervention (Figure 2). The impacts then level off at a lower-than-baseline level, which shows that each intervention succeeds in extending product use to some extent, which decreases production rates. Although both the Reliability and Repair scenarios display signs of lowered production in 2050, their impacts evolve differently. The Reliability scenario results in elevated levels of emissions in the entire period 2025-2030, with the curve almost parallel to the Baseline curve, proving little initial effect. On the other hand, in the Repair scenario the impacts initially soar in line with Reliability, but then gradually diverge. This gradual decrease in impacts corresponds to immediate effects offered by the Repair scenario, which targets all in-use products and prevents 20% of them from being discarded due to failure.

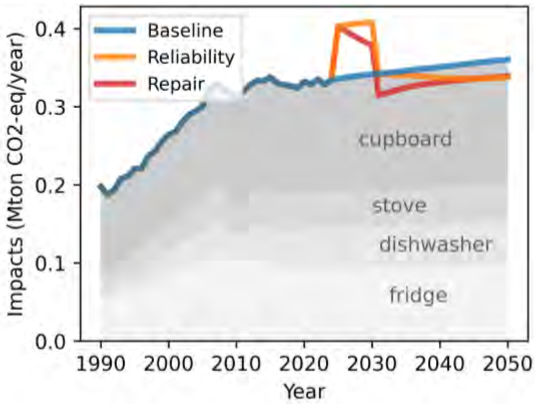

**Figure 2. Annual climate change impacts – the totals for each scenario (line plot) and the Baseline composition by durable type (stacked area plot). Assumed a penalty of 100% of the impacts in 2022, spread over 5 years.**

How environmentally beneficial a scenario is, is evaluated using the net impact with respect to the baseline (Figure 3). The net effects depend on the environmental penalty – the more resources we need to invest in executing an intervention, the more benefits are needed to offset it. However, some scenarios become beneficial (negative net impact) sooner than others. For example, assuming a penalty of 100% of the impacts in 2022 (just like shown in Figure 2), most scenarios show an impact increase: Reliability +1.5%, Connection +3.1%, Repair -1.3%, Culture +2.1%. The Connection scenario can therefore be the most detrimental to the environment, while the Repair scenario is an environmental benefit in most cases. Interventions involving absolute obsolescence are more effective (Repair, Reliability) than those involving relative obsolescence (Culture, Connection), given that the majority of kitchen durables are still discarded because of failure. Interventions targeting in-use products (Repair, Culture) yield faster effects than those targeting on-the-market goods (Reliability, Connection), which gives preference to them in a shorter time horizon.

## Discussions

When designing lifetime extension strategies, it is important to address the weakest link within the list of factors that determine obsolescence. For kitchen durables, the weakest link is typically the product's technical reliability, but also the degree to which repair services are used. The modeling work shows that lifetime extension measures focused on these aspects yield higher benefits than those of measures focused on relative obsolescence. However, the benefits might not be as high as expected, because by addressing absolute obsolescence, the Reliability and Repair scenarios leave the relative obsolescence aside. This creates a rebound effect, where the intervention planned for extending product lifetime by 20% can only address its technical component, while the social lifespan remains unchanged and thus decreases the potential benefits down to barely a few percent.

The results also show that design-based solutions to longer life bring environmental benefits only in a medium-to-long timeframe. Although design for durability has gained a lot of interest in research and policy, the supporters of such solutions typically overlook what it takes to replace all products with more durable equivalents. The model developed in this work considers such systems dynamics, demonstrating that the longer the products last, the longer it takes to replace their entire stock. The potential environmental benefits may come too late considering many countries' climate goals set for 2050. In fact, this work has shown that policy extending technical lifespan through design (scenario Reliability) could be counter-effective for 2050 climate goals, increasing the net climate change impacts by up to 6%, assuming an environmental penalty size of 200% of the impacts in 2022. Although the penalty size considered in this work was chosen arbitrarily, any kind of intervention certainly involves some environmental costs. Lifetime extension strategies are generally not for free so carefully planning the details of their implementation can prevent a backfire effect.

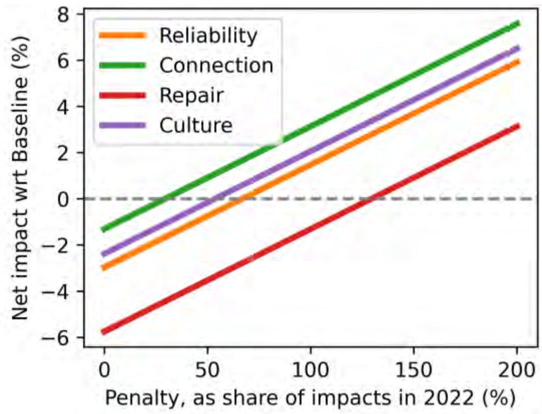

**Figure 3. Net environmental impacts with respect to the Baseline as a function of the penalty size.**

To overcome the time delay of design-focused measures, we suggest that a change to more user- and system-focused legislation might be beneficial. For example, faster environmental benefits could be achieved by increasing the repair rates by extending product warranties, subsidizing repair services, supporting the development of innovative repair businesses, demanding the availability of spare parts at affordable prices, and increasing the convenience of repair. Ideal policy proposals could target products with a high share of absolute obsolescence, e.g., dishwashers, which also fail more frequently than other appliances (Laitala et al., 2021). Products with high relative environmental impacts could also be prioritized, e.g., lifetime extension of kitchen cupboards could bring more benefits than any one kitchen appliance.

Finally, this work assumed that relative and absolute obsolescence are independent. This might not be the case in reality, as absolute and relative obsolescence can influence each other. There exists qualitative evidence that absolute and relative obsolescence of kitchen and kitchen durables can coexist, i.e., Amilien et al. (2004) noted that their respondents often started motivating their recent kitchen renovation by describing timeworn kitchen items, to finish off by criticizing the kitchen looks. Sometimes the absolute obsolescence of one item can cause the relative obsolescence of another, acting as a trigger, like in the case of a family that "needed to replace the floor joists, [so] they took the opportunity to completely transform the kitchen at the same time" (Hagejärd et al., 2020). Following this, we could speculate that an increase in the technical lifespan of one kitchen durable could in turn extend the social lifespan of interconnected goods, which could otherwise get discarded too. However, these interdependencies were not included in the current model due to a lack of quantitative data. Future work could involve collecting more evidence on the interaction of absolute and relative obsolescence.

## Conclusions

This work explored four different scenarios implementing lifetime extension of kitchen durables. Although these goods are known for the importance of their technical lifespan, we show how the focus on absolute obsolescence and leaving out the relative obsolescence might decrease the environmental benefits of these scenarios, which could be seen as a type of rebound effect. We also show that design-focused interventions take longer to bring effect, which might make them counter-effective for climate goals set for 2050. We suggest that user- and system-focused policy might yield faster effects, just like a focus on particular durables.

## Acknowledgments

We would like to thank the Research Council of Norway for funding this work (Lasting project, 303080).

# Mending is not that simple. What set of competencies can enable mending practices, and how can we learn them?

**Iryna Kucher** [(a)], **Ulla Ræbild** [(a)]
a) Design School Kolding, Kolding, Denmark

**Keywords**: Clothing use phase; Clothing maintenance; Mending competencies, Mending education.

**Abstract**: In the past, mending was taught in schools. Today, despite an upsurge of mending practices, this learning mainly occurs in the setting of participatory workshops, which have sporadic nature and are primarily focused on the expressive dimension of clothing repair. Yet, mending practices are complex. They encompass different dimensions of clothing repair and require a vast set of competencies. This paper argues that one of the answers to how we can reduce the impact of our wardrobes in the use phase resides in reintroducing the practices of clothing care and mending into the educational system. Our paper draws upon the analysis of three case studies of Design School Kolding (DSKD) students who have chosen to work with mending in their design projects at BA, MA, and PhD levels. The findings of our research demonstrate the dependence of mending on other maintenance, craft and design practices and indicate that acquiring mending competencies in conjunction with other related skills is essential for increasing the lifespan of clothing and, therefore, achieving sustainability in the fashion sector.

## Introduction

Despite the evidence of the shocking environmental impacts caused by the fashion industry (Niinimäki et al., 2020; Allwood, 2006 et al.), little is fundamentally changing, and clothing production continues to grow (European Environment Agency, 2022). Simultaneously, the information regarding the environmental and social impacts caused by the fashion sector has reached larger audiences (Ditty, 2017), and the generations born in the '80s and '90s have started to adopt dematerialisation as a strategy of resistance to capitalism and consumer culture (Durrani, 2019; Egereva & Gurova, 2014). It has resulted in a budding transition from a fast to a slow rhythm of consumption, with its characteristic features: the popularity of second-hand consumption, the purchase of handmade locally produced fashion products, circulation, upcycling, personalisation, repair, and maintenance of clothing (Gurova, 2015, Fletcher, 2008). Within this framework, clothes' longevity, durability, and practicality are valued. And statements such as 'mending has died out' (Clark, 2008) have lost their actuality and have been surpassed by 'mending revolution' (Klepp, 2022), which actively gains popularity both in Western and Eastern post-socialist countries (Kucher, 2022). As evidenced by the growing number of non-academic publications on mending and growing interest towards mending on social media, more and more people are trying to enact mending practices. However, the possibilities to acquire mending competencies are limited, and they mainly occur within the setting of repair cafes and participatory workshops, which have sporadic nature and are primarily focused on the expressive dimension of clothing repair (Kucher, 2022; Durrani, 2019). Yet, mending practices are complex and go beyond learning basic mending techniques. They encompass different dimensions of clothing repair and require a vast set of competencies.

*Mending and design*
Simultaneously, also designers' interest in mending is growing. If, in the past, clothing repair was rarely approached by designers and design researchers, today, at Design School Kolding, where education brings value to mundane clothing practices (Ræbild and Riisberg, 2021), we observe an ever-growing number of students engaging with mending. In this paper, therefore, we propose to explore what such engagements can teach us about the practice of clothing repair. In the first part of this paper, we will present three case studies of design students who worked with mending. In the second part of this paper, we will examine the common denominators of these three projects and discuss how mending competencies can be acquired.

## Method

Our paper draws upon the analysis of a collective case study (Stake, 1995) of six DSKD students carried out in spring 2023. The case study involved three different design projects intending to generate an appreciation of designers who have actively chosen to work with mending to enable a systemic change within the field of fashion. The number of case studies was carefully selected in relation to different levels of design education and the nature of the projects, comprising a teaching element and focusing on practices, processes, and material flows related to the phase of clothing use (Laitala and Boks, 2011; Fletcher, 2008).

The dataset included descriptions and presentations of the design process and outcomes of the students' projects, which were organised and clustered by paying attention to variations within each case and the relationships between different causes and outcomes. Firstly, was analysed the data related to each case and subsequently was made a comparison across cases.

## Mending in design practice

*Case nº1*

The first selected case relates to Christine Beate Kjos-Hanssen Husøy's (CH) graduation project, conducted within a textiles BA programme in 2020. CH's project entitled 'Teaching sustainable clothing habits' was carried out in collaboration with UN Associations Norway (UNA) and addressed the new national curriculum for the Norwegian educational system, aiming at supporting pupils' in-depth understanding of the future's societal and environmental issues (Udir, 2020). CH asked: 'How can I create learning activities for teachers to enlighten and motivate pupils aged 12 to develop sustainable clothing habits?' To answer this question, CH structured her project around the 6C model – a framework which facilitates the design process through observation, understanding, and acting on diverse design approaches (Friis, 2016). Accordingly, the project consisted of developing, testing and evaluating learning activities and was divided into three stages.

Within the first and second stages of the project, CH conducted a series of interviews with 22 children and educators from the primary school and UNA. The insights of these stages were utilised to develop six learning activities, which were subsequently tested involving 60 pupils from year seven at Hallset Primary school in Trondheim, Norway. In this paper, we will briefly illustrate one of the activities, which aimed at teaching the pupils practical mending skills to prolong the phase of clothing use.

The 'Mending techniques' activity consisted of trying out four mending techniques of different difficulty levels: sewing a button, patching, darning and embroidery. To support and guide pupils, CH prepared four videos, which included inspirational mending examples and

explanations of the mending procedures. Moreover, the designer provided DIY mending kits for those pupils who did not have the necessary mending equipment. The assignment delivery consisted of the photograph of finalised mending sample (Figure 1).

With a few exceptions, all pupils delivered their mending exercises, which varied in quality of execution. Almost everyone managed to sew a button and patch a hole, while darning and embroidery were considered more laborious and time-consuming. As evidenced by samples, some students received help from their family members, the designer concluded that the activity allowed pupils to acquire a basic understanding of mending techniques and, therefore, has the potential to support pupils' behavioural development of sustainable clothing habits both in schools and within a domestic landscape.

**Figure 1. Documentation of mending activities carried out by pupils at Hallset Primary school in Trondheim, Norway. Photo credit Christine Beate Kjos-Hanssen Husøy.**

### *Case nº2*

The second case regards the project 'Selected to last', which was developed by four MA students: Leonie Heise (LH), Daksh Chhillar (DC), Jogalie Zairyte (JZ) and Selma Momme (SM). In autumn 2022, during the third semester of the master studies, students from 'Design for Planet' (LH, JZ, SM) and 'Design for people' (DC) interdisciplinary programmes worked together within the course 'Design for Behavioural Change'. This course introduces students to design that engages people in changing everyday cultures by imagining alternative futures and offers students the opportunity to collaborate with external partners. The group chose to work with the Danish fashion brand SELECTED. The company was aware of the upcoming UE textile strategy (Directorate-General for Environment, 2022) and, therefore, invited students to investigate how the brand could enable its users to prolong the use phase of their products.

**Figure 2. Public intervention, set up by students in the Kolding store centre. Photo credit Selma Momme.**

**Figure 3. First participatory workshop of 'Selected to last' project. Photo credit Daksh Chhillar.**

The students formulated their research question accordingly: 'How might we enable SELECTED to engage end users in care and maintenance practices that prolong the garments' lifespan?' To answer this question, it was essential for the group to have insights regarding both users' maintenance practices and the company's understanding of clothing longevity. Therefore, the project's first step consisted of public intervention in the Kolding store centre (Figure 1) and a participatory workshop with four participants (Figure 2). This stage aimed to understand if users had enough knowledge regarding laundry and mending practices.

To facilitate the research process, designers developed a series of design artefacts (Figures 2 and 3), which allowed the group to understand that users wished for more durable goods while simultaneously missed basic knowledge of mending and maintenance. For instance, all selected participants could not read the care labels, frequently washed their clothing at high temperatures and discarded stained or broken garments. Designers utilised these insights during their visit to SELECTED headquarters, where they met textile engineers and designers to investigate the company's sustainable goals. This visit evidenced that the brand was unfamiliar with the use practices of their customers and, in the design phase, was considering exclusively products' physical durability. Moreover, SELECTED had difficulty communicating its sustainable strategy to the end users due to the fear of greenwashing.

The main challenges encountered by the brand were utilised to build the second intervention, which took place in the brand's retail point and consisted of testing the prototypes developed by students aiming at building their further understanding of the users' clothing practices (e.g., visible care labels placed on different parts of the garments to understand which kind of label would enable consumers to care better for their clothing (Figure4).

Within the last stage of the project, students challenged the brand team with questions derived from end users' quotes. This activity prompted the SELECTED team to realise that, firstly, to communicate their values to the customer, they had to define the term 'longevity' for the company. Secondly, the company put a great responsibility on consumers by focusing exclusively on physical material durability, pretending that final users would know how to care correctly about their clothing. Therefore, the company decided to consider alternative design strategies. Thirdly, the company became aware that education about clothing care and maintenance is needed both for SELECTED final users and its employees.

**Figure 4. Visible care labels placed on different parts of the garment. Photo credit Jogalie Zairyte.**

### *Case n°3*

The third case study considers Iryna Kucher's (IK) ongoing PhD project, 'Mending methods' (2020-2023). Based on the practice theory (Shove et al., 2012) and the theory of consumption temporalities (Gurova, 2015), IK assumed that the answers regarding how to rediscover and redistribute mending knowledge are concealed in a mundane repair culture of the post-socialist world, where mending has never ceased to be relevant cultural practice. Accordingly, to understand what competencies comprise mending and how these can be enacted, IK proposed comparing existing mending practices in Western (Danish) and Post-socialist (Ukrainian) contexts.
To carry out the in-depth mending exploration, IK has selected a group of six participants practicing mending regularly (three from Denmark and three from Ukraine) and articulated the overall project into five stages. The study began with a series of wardrobe interviews to understand what garments participants mend, how they do it, what

motivates them to mend, and what materials and equipment they use. This phase allowed IK to frame the contextual insights and to translate different ways of participants' knowing into a series of design research artefacts utilized to facilitate the following project stages.

The third stage of the research consisted of two participatory mending workshops, aiming to capture the overall group's mending experience and understand which competencies are utilized when mending practice is enacted. Finally, the 4th and 5th stages explored how study participants navigated the complexity of the expressive dimension of the mending approach by undertaking design activities of planning and visualizing their mending projects. Among the findings relevant to the following discussion, firstly, we would like to distinguish different levels of engagement with mending practice, such as basic, discrete and expressive dimensions of clothing repair. These findings emerged from wardrobe studies illustrating an array of mending examples. Despite recent interest in an expressive dimension of mending, all wardrobe studies also portrayed basic and discrete clothing repair approaches.

As evidenced in Figure 5, these approaches vary in complexity and require different competencies. Secondly, the research demonstrated how mending practices collaborate with other maintenance, craft and design practices by utilizing other practices' elements, such as competencies and materials. Accordingly, mending together with other practices of care (i.e., laundry, drying, storage), craft practices (i.e., clothing construction, knitting, embroidery), and elements of design practice (i.e., planning, visualizing, and life cycle thinking) constitute practice complex, which characteristics cannot be reduced to the individual practice of which they are composed (Shove et al., 2012). Finally, the study illustrated that in the Ukrainian context, mending is still taught in schools. Therefore, everyone can learn how to prolong the lifespan of their clothing by acquiring mending knowledge, taught in concomitance with other competencies of care and craft.

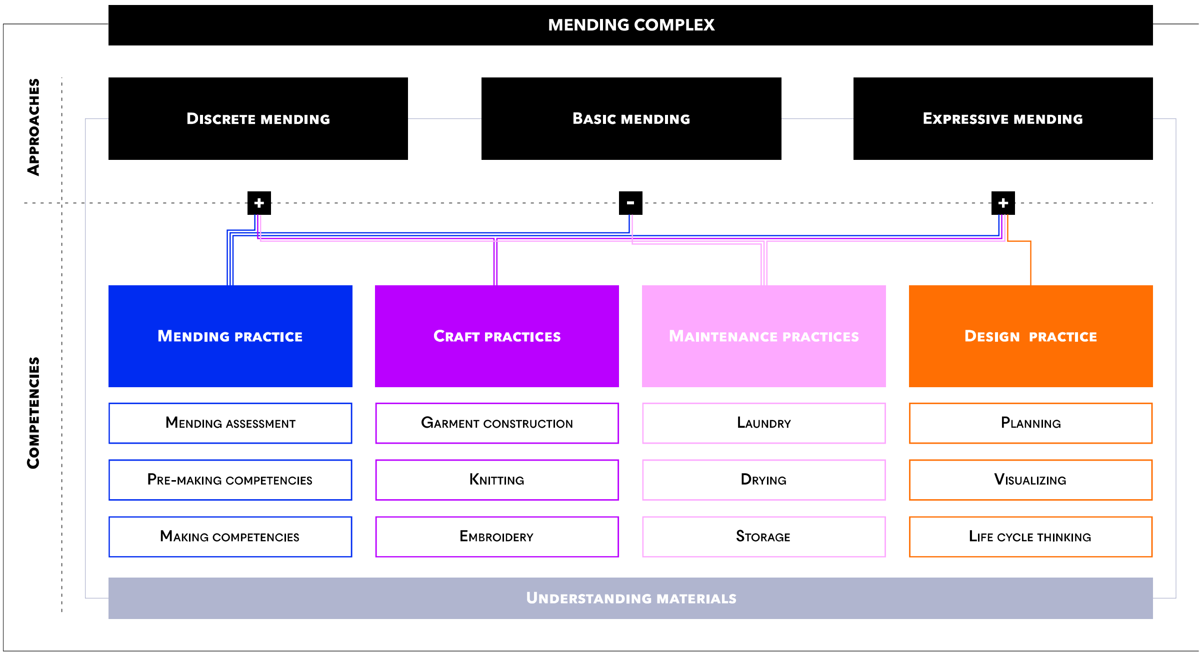

**Figure 5. Mending complex constituted by different mending approaches and competencies borrowed from other practices.**

## Concluding discussion

As evidenced by the three case studies illustrated above, bringing value to the use phase of clothing consumption in design education prompts students to increase their interest in consumers' behaviour and to integrate mending in their projects in different ways. While framing projects' contextual insights, the students became increasingly aware that multiple dynamic processes shape mending practices and approached mending practices holistically.

Comparing the cases allowed us to identify the projects' common denominators and conclude that all projects recognized the dependence of mending on other care practices and their competencies. For example, in case 1, CH has developed teaching material comprising wardrobe activities, such as complete wardrobe audits (to build pupils understanding of the dormant clothing in their closets) and investigation of washing habits (to bring attention to the impact of frequent washing routines). These activities put mending into relation with other practices of care. Similarly, also case 2 approaches mending holistically. By looking into the interventions designed by the students, it is evident that according to LH, DC, JZ and SM, the users should know not only how to wash, dry and iron their clothes but also be able to react to hypothetical accidents such as a stain or iron mark. Analogously, the exploration of users' mending practices in case 3 demonstrated that how clothing is washed, dried and stored affects the clothing material longevity and therefore requires more or less mending.

Secondly, all three projects recognize the importance of developing mending competencies gradually. It is evident when CH proposes to begin with learning the basic mending techniques on intact fabric sample, and only when these competencies are acquired – to continue with mending a damaged garment (since mending the latter require additional competencies such as analyzing the damage and choosing an appropriate treatment). The sequence of interventions of case 2 indicates that the group of students recognizes that taking better care of the garments is easier than dealing with a complex repair, and therefore decides that the users' learning should begin with learning how to wash, dry and iron clothing. While case 3 distinguishes three different levels of engagement with practice: basic, discrete and expressive mending, and demonstrates that users can learn more sophisticated mending approaches only after acquiring the basic knowledge of clothing repair.

Finally, all the cases comprised a teaching element, indicating the potential of re-introducing the practices of care and craft into the educational system on different levels. Case 1 addressed the Norwegian new national curriculum for the school educational system, recognizing the importance of supporting pupils' development of mending competencies, while case 3 illustrates how teaching mending in schools enables children to develop life-long clothing care competencies. Simultaneously, case 2 indicates that designers, companies and their end-users lack the basic skill set related to mending. Therefore, to achieve sustainability in the use phase, also people who have already completed their education must acquire a mending skills package as well. This learning can be enabled by developing alternative educational frameworks which do not have a sporadic nature and address mending holistically. We conclude that more research on mending within an educational context is needed since how mending was and is taught in various educational and social contexts is underexplored.

## Acknowledgments

We would like to thank Christine Beate Kjos-Hanssen Husøy, Leonie Heise, Daksh Chhillar, Jogalie Zairyte and Selma Momme for contributing with their projects. We would also like to thank Design School Kolding for funding this research.

# Stability studies of biocolourants

**Laaksonen, Päivi[(a)], Helander, Roosa[(a)], Jordan, Juha[(a)], Virta, Nea[(a)]**
a) Häme University of Applied Sciences, Hämeenlinna, Finland

**Keywords**: Biocolourants; Dyes; Accelerated weathering; Indigo; Tannins.

**Abstract**: One of the key elements of sustainable design is to ensure that the product has a long life-time. Change in the product appearance is a reason to abandon it from use and is much correlated to the colouration of the product. When proposing the use of bio-based organic colourants in products, such as garments, furniture, vehicles or other goods, one has to pay attention to their stability, because they are generally vulnerable to the external stresses such as temperature changes and sun light, that may have an effect on their colouration upon use. This work focuses on the research of stability of biocolourants, which relates to the theme "Colour and product lifetime". The paper includes two experimental case studies 1) indigo-dyed coatings on wood, and 2) plant-based bioinks on cardboard.

## Introduction

The expected stability of a product's colour is related to the anticipated life-time of the product and depends on the exposure to environmental, chemical or mechanical stresses or several of these. The spectrum of product life-times, the conditions for environmental stress and the relevance of the colour and its changes for the products are large. For instance, the stability requirement for a car paint differs very much from that of a disposable package, and therefore the material choices, including the colourants, are typically made based on different reasons. Besides the colour and its stability, colourants may also have requirements related to their safety properties or degradation mechanism.

As steps towards sustainable manufacturing and circular economy are taken, more and more attention needs to be paid to the whole life cycle of materials. As different colourants are consumed in large quantities, hundreds of tonnes annually (DCP, 2022), in textiles, paints, packages, cosmetics and other products, their contribution in the product life cycle should also be considered in the ecological product design. In the case of dyes and colourants, sustainability means transferring to non-fossil raw materials, utlisation of side-stream materials, long product life-times and safe use and end of life phases. Sustainability of production turns our attention towards bio-based colourants, *i.e.* biocolourants, whose industrial scale production and use are still developing. However, there are many applications where biocolourants have been investigated. (Shahid, 2013; Khoo, 2017; Nambela, 2020) In many cases, products coloured with biocolourants are produced by crafters and artisans on small scale and they do not go through systematic product development processes including colour fastness assessment and other standardized tests that are carried out for commercial products. Therefore, there is a lack of knowledge on the stability of biocolourants, especially in application areas other than textile. In this study, we focus on the colouration stability of biocolourants aimed at wood coatings and printing inks.

The testing standards and practical experience of product manufacturers guide the process for estimating the expected times, after which the product will undergo visible changes in their appearance or changes that will cause loss of functionality or applicability. These changes may be due to instability of the colourant but also due to other changes that occur in the materials. For example, for a coating applied on a sheet metal, the changes upon time can be, sequential fading of colour, damaging of the coating layer and corrosion of the underlying metal. For the sake of sustainability and slowing down the overconsumption, it is important to be able to distinguish the changes that lead to abandoning of the product. For a coated sheet metal, such as roof top material, the critical change may be the corrosion that occurs after tens of years, whereas for a garment, it may be the first visible changes in the colour.

Therefore, in assessing the needed stability of the colourants, it is utterly important to carry out tests in conditions that match the target application environment of the product, bearing in mind the expected product life-time. In this work, we present experimental studies on the stability of plant-based colourants obtained from woad (*Isatis tinctoria*) and wood barks (spruce, willow) carried out in various experiments simulating the application environments of coatings for wooden facades and prints on cardboard or plastic packages.

## Experiments

### *Materials*

The coating stability experiments were carried out by coating pine samples with linen oil containing colourants of interest (Figure 1A). Natural indigo of *Isatis tinctoria* (Natural Indigo Finland), synthetic indigo (Sigma-Aldrich) and Ultramarine (Uula Color Oy) powders were grinded with a planetary ball mill and mixed with linen oil (Uula Linseed Oil, Uula Color Oy) in 5 wt-% and applied as coating on pine surface. 4 layers of oil were applied by using a brush. Samples without coating and with unpigmented linen oil were used as reference. (Helander, 2020)

The bioink experiments were carried out with dyes extracted to water from spruce bark, (*Picea abies*), willow bark (*Salix Klara*) and walnut shells, that all contain coloured tannins (Kemppainen, 2014; Fraga–Corral, 2020). All the biomasses were pre-treated mechanically to coarse powder to facilitate the extraction of soluble compounds. Hot water extraction at 80 °C was carried out for willow and walnut and accelerated solvent extraction (ASE , Dionex ASE 350 – Accelerated Solvent Extractor) method was applied for recovery of the biocolourants from spruce. The conditions for ASE were optimized using design of experiments, all the details are included in the thesis of Virta (2022). Shortly, a series of experiments were done at 1500 psi pressure by varying the extraction temperature between 105 and 190 °C, extraction time between 5 and 30 min and amount of the biomass between 0.2 and 1.1 grams. The optimization was done against the detection signal at 280 nm, which was used as the measure for extracted tannins. Water was removed from the extracts by rotary evaporator and eventually air drying (Figure 1B). Natural indigo of *Isatis tinctoria* was obtained as a powder (Natural Indigo Finland). For the experiments, bioinks were mixed with each other and iron sulfate and dispersed in water so that the in mass of dyes was always 20 wt-% of the ink. The test prints were done by spreading the bioink on cardboard using a paint brush. The mixtures of the ink components were planned systematically and their colour and stability were analysed.

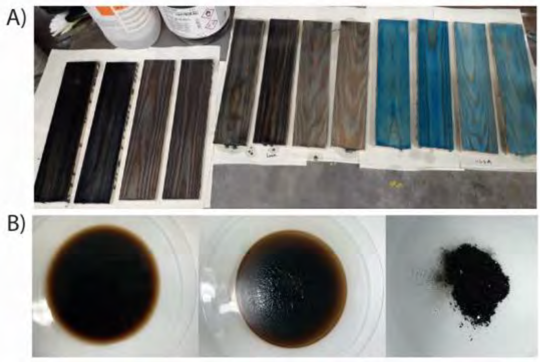

**Figure 1. A) Pine wood samples coated with linen oil coatings. B) Drying process of spruce bark extract from concentrate to powder.**

### *Testing and research methods for various environmental stress conditions*

For paints and varnishes that are intended for outdoor use, the best way to ensure their sufficient chemical and physical stability is to expose them to realistic climatic stress for a time period long enough and assess changes that happen as function of exposure time. In practice this means placing the products on outdoor testing sites for several years, because the expected life-time of the products is typically tens of years. To accelerate obtaining the knowledge on long-term durability of materials and the development of new products, artificial weathering tests simulating the outdoor conditions in shortened time period have been developed. The tests often include exposure of the samples to light (UV or Xenon), temperature, moisture or some other chemical environment (Gulmine, 2003). The testing times vary from weeks to months instead of years. The harshness of the conditions is brought about by cyclic variation of the stress factors, that cause faster damage to the studied materials than exposure to constant conditions. The intention is to simulate natural variation of conditions and therefore cyclic variation of temperature, lighting and humidity are typical.
For investigating the stability of coatings pigmented with natural indigo, we chose a

testing procedure that consisted of four-hour long periods of alternating UV radiation at 60 °C and a condensation phase including water spraying at 40 °C (Figure 2A). (ISO, 2018) These periods were repeated for 12 weeks time in total. The changes occurring on the coating were assessed by measuring the colour every week.

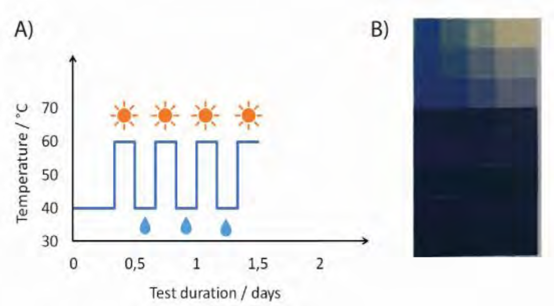

**Figure 2. A) The conditions of the artificial weathering test. B) The blue wool standard used as reference for assessment of light fastness. The most stable sample is located at the bottom of the image.**

For products used mostly indoors or outdoors for a limited amount of time, such as textiles and packages, the stability against environmental stress is studied using exposure to light and humidity. Also tests simulating the maintenance of the products, such as washing and mechanical rubbing can be carried out. The assessment of the bioink was carried out by modifying a test commonly applied for textile ligh fastness (ISO, 2014) where fading of the tested sample under exposure to Xenon light is compared to a known standard (Figure 2B). (Aydemir, 2018) For the bioinks, colour and coluor change in the 7 days exposure to Xenon light was measured and grade (1-8) was given based on the extent of colour change according to the light fastness standard. We also screened the recipes by aiming at dark colour as black as possible. The spreadability of the ink and adhesion on cardboard substrate were assessed on subjective scales 1-5, 1 being poor and 5 excellent. Spreadability grade was given by the homogeneity of the print when the ink was applied using a paint brush. Adhesion of the bioinks were tested using a Scotch tape and scratch test of the print. (Virta, 2021)

### *Assessment of the colour and stability*

Assessment of the colour stability can be carried out visually, but the commonly used practices, such as the standards often guide towards precise and repeatable methods, such as measurement using spectrophotometer, which can tell exact changes in colour intensity and tone. For visual inspection, there are often visual references and guidance for repeatable measures.

There are numerous ways to describe colour space, and a typical colour system used when measuring colour is the CIELab colour space that describes each colour using a measure for its lightness ($L^*$) and colour on two coordinates, $a^*$ for green to red and $b^*$ for blue to yellow. On this system all the coordinates for black are zero, and for white $L^*$ is 100, while $a^*$ and $b^*$ are zero.

## Results

### *Stability of the indigo coatings*

The measured CIELab colour values of the coating before exposure to the weathering are presented in Table 1. The smaller the $b^*$ value, the more blue the original colour was. All the pigmented samples clearly deviated from the uncoated and unpigmented samples and also had lower $L^*$ value indicating to darker colour. The commercial ultramarine pigment had originally the highest colouration values, whereas the synthetic pigment was very dark and almost black at the beginning of the experiment.

The colour changes in the samples coated with linseed oil after 12 weeks of exposure are shown in Figure 3. The total colour change $\Delta E$ can only have a positive vaue and is calculated from the change of $L^*$, $a^*$ and $b^*$ coordinates using the equation:

$$\Delta E = \sqrt{(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b^*)^2}$$

whereas the other changes were obtained as subtraction of the measured values after 12 weeks of weathering and at the beginning of the experiment. For all of the samples there was some change in the total colouring and increase of brightness. All the pigmented coatings went through less darkening than the uncoated wood, the indigo-containing samples being the ones to change the least. The increase of $b^*$ indicates to yellowing, which is a typical visual change in pine wood upon ageing and the indigo samples and the ultramarine pigment could resist this change rather well. Overall, the darkest sample with synthetic indigo changed the least, ultramarine the most and the natural indigo fell in between these.

| | *L* | *a** | *b** |
|---|---|---|---|
| Uncoated | 78 | 6 | 23 |
| Natural indigo | 41 | -1 | 12 |
| Synthetic indigo | 30 | 0 | 5 |
| Ultramarine pigment | 53 | -27 | -13 |
| Unpigmented linen oil | 63 | 17 | 40 |

**Table 1. The measured colour values of the wood samples with oil coatings.**

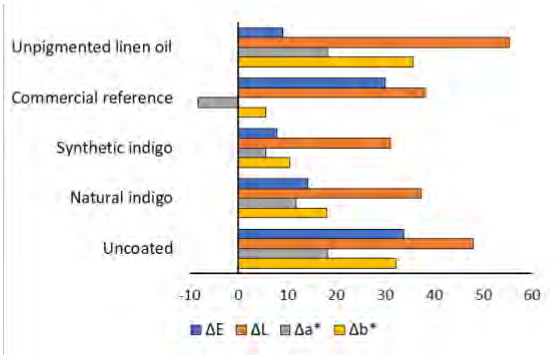

**Figure 3. Colour changes, in the linseed oil coates samples after 12 weeks of accelerated weathering exposure.**

### *Colour and stability of the black bioinks*

As a result of screening the properties of good candidates for black and stable bioinks, four optimal compositions were identified. The percentage of each dye or additive components are given in Table 2. All of these recipes contained indigo, which turns the brown colour of tannin towards black as well as ferrous sulfate which typically darkens the colour of tannins and enhances their ligh stability. (Fraga–Corral, 2020)

| Sample | Indigo (%) | BW (%) | SB (%) | W (%) | Fe (%) |
|---|---|---|---|---|---|
| Ink 1 | 15 | 75 | - | - | 10 |
| Ink 2 | 15 | - | 75 | - | 10 |
| Ink 3 | 30 | - | 65 | - | 5 |
| Ink 4 | 30 | - | - | 65 | 5 |

**Table 2. The composition a few very black and stable bioink dye formulations. Indigo = woad-based indigo, WB = willow bark, SB = spruce bark, W = walnut and Fe = ferrous sulfate.**

The results of the stability assessment for the oprimised bioink recipes are summarized in Table 3. The measured *L** values have very low values, even compared to iron oxide which is a typical black pigment for screen printing, meaning that the bioinks are truly black in colour. The light fastness grades, the spreadability and the adhesion on the cardboard are mostly very good or excellent for these dye mixtures, which indicates to the high potential and technical performance of the bio-based inks.

| Sample | *L** value | Light fast-ness | Spread-ability | Adhesion |
|---|---|---|---|---|
| Ink 1 | 8,5 | 6 | 4 | 4 |
| Ink 2 | 8,5 | 7 | 5 | 5 |
| Ink 3 | 7,9 | 7 | 5 | 4 |
| Ink 4 | 8,2 | 8 | 5 | 4 |
| Iron oxide | 24,6 | 6 | 5 | 4 |

**Table 3. Properties of bioink formulations. The measured value for lightness *L**, the grade for light fastness (1-8), spreadability assessed by brushing ink on the cardboard (1-5) and adhesion assessed by a tape and scratching tests (1-5).**

## Conclusions

As a result of exposure to accelerated weathering and milder light stability tests, we always observed changes in the colour of the studied coatings and prints whether they were pigmented with a biocolourant or a commercial reference pigment. The presented wood coating solutions clearly showed the potential of utilizing natural indigo even in wooden facades or other wooden surfaces. Especially the synthetic indigo showed a great performance in colour stability even when compared to a commercial reference pigment. The possible reasons for the mediocre performance of the natural indigo compared to the synthetic indigo in the presented experiments are the impurities that the natural product contains and the translucent coating that allows the changes in wood colouration to occure and show. Similar observation has been made in an earlier study by Jordan *et al.* (2022) Raw materials and production process of the natural indigo contains sources for organic and inorganic impurities and further studies regarding the role of these impurities in the stability will be needed.

The bioink recipes that were obtained by systematic study of the recipes containing tannin-rich extracts, natural indigo and iron sulfate and optimization of the darkness and light stability showed very promising colouration, stability and adhesion properties on cardboard substrates. The presented systems however, were prepared using water as the solvent and further development towards faster evaporating solvents such as alcohols are needed for real printing applications.

In this study, we demonstrated stability assessment on two different application areas of biocolourants having different product life-times and ageing environment. As a conclusion, it can be stated that biocolourants require careful formulation and stability assessment before they can enter the large scale applications, such as pinting and facades. However, the promising results obtained with low value raw material, such as the wood barks, shows the potential of feasible and high performing colour applications, as soon as the obstacles of poor stability are overcome. It is also good to bear in mind that we have a habit of over engineering materials. Perhaps, through biocolourants we can learn more of the Nature's way to design materials to be "good enough" for their life-time and purpose.

## Acknowledgments

This work has been funded by the "Bio Based Dyes and Pigments for Colour Palette (BioColour)" (Grants 327209, 352465) project supported by the Strategic Research Council at the Academy of Finland.

# Why won't you complain? Consumer rights and the unmet product lifespan requirements

**Kirsi Laitala[a], Lisbeth Løvbak Berg[a], Pål Strandbakken[a]**
a) Consumption Research Norway (SIFO), Oslo Metropolitan University, Norway

**Keywords**: Complaint; Regulation, Consumer behaviour, Quality, Acquisition.

**Abstract**: The consumer purchases act is one of the cornerstones for ensuring that businesses are liable for defective or faulty products that do not meet the minimum requirements for lifespans. However, this right is too seldom used by consumers. This paper discusses the reasons for not complaining based on six consumer focus groups, where in total 36 consumers described furniture, electronics, and textile products that they were dissatisfied with. Many complaints were not made due to consumers' cost-benefit evaluations, where they considered the economic costs, time use, and the needed effort, as well as the probability of getting the complaint accepted. Many participants lacked the competencies required to make the judgment when the right is applicable and where and how to proceed. Further, the expectations based on price and brand, properties of the product such as materials, as well as the type of fault and its relation to use were important. Strengthening and extending consumer rights to complain are discussed as an important part of the strategy to increase the quality of goods and extend their lifetimes. The findings show barriers and opportunities to the efficacy of this strategy that is highly relevant for policy development. There is a need for clear guidelines on what the consumer rights are for the specific products, what is considered unacceptable abrasion and normal use, and differentiation between commercial warranties and legal rights. Complaints are an important avenue for businesses to gain information about the performance of their products, and for legal durability expectations to be enforced.

## Introduction

Consumer rights legislation is one of the cornerstones for ensuring businesses' liability for defective or faulty products that do not meet the minimum requirements for lifespans (EU, 2011). Therefore, consumer complaints have the potential to influence product lifetimes indirectly. According to Hirschman's Exit, Voice, and Loyalty theory (1970), when confronted with poor-quality products, consumers can choose to exit (leave the liaison), voice the complaint and thus attempt to repair or improve the situation, or they can choose to remain loyal to the manufacturer, despite the negative experience. Consumer awareness, knowledge and activity, supported by a legal framework, are key factors in developing well-functioning markets and reducing the amount of faulty and low-quality products.

In Norway, the Consumer Purchases Act (Forbrukerkjøpsloven, 2002) gives consumers the statutory right to complain to the seller in the event of errors or defects in purchased goods within a two- or five-year period post acquisition, depending on the expected lifespan of the product. Similar legislation is in place in all European countries, but with varying time limits from a minimum of two years (Forbruker Europa, 2018). If the manufacturer or seller cannot repair the product, the buyer will have the right to receive a new product or a refund; withdrawal or compensation, depending on the type and size of the defect.

The proposal for the Green Claims directive in the EU will further improve consumer rights by ensuring that consumers obtain reliable and useful information about products, e.g., on their lifespan and repair options, to prevent greenwashing and sale of products with a covertly shortened lifespan (EC, 2023). Such legal measures are meant to discipline the suppliers, bringing better quality and repairable products to market.

In this paper, we will discuss consumers' dissatisfaction with products and why it often does not lead to complaint to the seller, even when the legal basis for making the complaint exists. Further, we will propose measures that could increase the complaint rate for faulty products, as a potential pathway for producers to improve their products based on feedback from their customers.

In the next sections, we briefly introduce the theoretical background and our method based on consumer focus groups. We focus on three high-impact categories: household appliances, furniture, and textiles.

## Background

A number of studies have focused on consumers' complaint behaviour (CCB) from various countries and product and service areas (Arora and Chakraborty, 2020). CCB studies in Norway have shown that consumers surprisingly seldom use their right to complain. EU's Consumer Markets Monitoring Survey (MMS) carried out in 2019-2020 showed that between 8% and 16% of consumers had experienced problems with the products/services they purchased where they felt they had a legitimate cause to make a complaint (Alecu, 2021; EC, 2020). The share was higher among Norwegians than the average of EU27 concerning all product groups studied in this paper. Further, a higher share of Norwegians proceeded with the complaint (72%-90%) than the average of EU citizens (49%-62%). This may relate to around 34% of Norwegian consumers displaying a high level of knowledge of consumer rights, which is among the highest scores in Europe (EC, 2021), but still shows that the great majority only have a low or medium level of knowledge regarding their rights (Alecu & Dulsrud, 2022; EC, 2021).

Other recent studies conducted in Norway show a much higher share of consumers experiencing problems, and a smaller share that complains. For example, in a survey where consumers were first introduced to their rights, a total of 36% reported having had problems with their clothing purchases, which is three times more than the MMS data indicates. Furthermore, only 44% of them had made a complaint, which is less than half of what was reported in MMS data (Bøyum et al., 2017).

One recent study from Norway has examined reasons for not complaining, and it only applies to online purchases. The main reasons were related to the respondents being unsure about their rights and difficulties in finding the right channels for complaints, the effort required compared to the price of the product or service, finding the necessary documentation, as well as previous bad experiences and not trusting that the problem could be solved (Alecu & Dulsrud, 2022).

General EU data indicates that the most common reasons for not complaining about recent clothing and footwear purchases were that the respondents had either resolved or fixed the problem themselves, couldn't be bothered, or didn't have time. These were followed by not thinking the problem was serious enough, or that the complaint would not be taken seriously. Some also relied on their previous experience of complaining and thought it wasn't worth it, while others didn't know how to complain or whom to contact, or felt that they were not good at complaining (EC, 2020). Several of the studies indicate that when complaints first were made, around 80% of cases were solved in favour of the complainant (Alecu & Dulsrud, 2022, Strandbakken & Bøyum, 2017).

Arora and Chakraborty (2020) conducted a comprehensive CCB literature review, and summarised CCB antecedents in five main topics:

1. Personal including the willingness and capability to stand up for one's interests, attitudes, demographics and personal characteristics such as extraversion and impulsivity, self-efficacy, perceived self-importance, emotions and time constraints.
2. Situational including likelihood of success, perceived responsiveness of the seller, cost-benefit expectations, type of failure and its severity and the associated perceived loss.
3. Cultural differences that represent a complex system of knowledge, norms, beliefs, values and morals that guides the formation and interpretation of shared meaning.
4. Relational including the relationship with the seller/manufacturer (duration, strength, trust, affection, etc,) prior experience with the firm, perception of the interactions, and psychological cost of switching.
5. Structural antecedents include macro-level regulatory policies as well as industry structure and its competitive nature.

Grønhag and Gilli (1991) suggest that it is possible to use a transaction cost approach to study consumer dissatisfaction and complaint actions.

## Method

The material is based on six consumer focus groups conducted in Norway, where we discussed product lifespans based on concrete examples that the participating 36 consumers gave on their furniture, electronics, and textile products. Before the interviews, they sent photos of products that they were either satisfied or dissatisfied with. A surprisingly high share of the descriptions were about malfunctioning products, where the consumers could have made a complaint based on the Consumer purchases act, but often had not done it.

The focus groups varied in location (Oslo or Trondheim), gender distribution (female, male or mixed groups), level of environmental awareness (high or mixed), and whether the participants had small children. 53% of participants were women and 47% were men. The participants' ages varied from 22 to 76 years, with an average of 46 years. All groups were administrated by two researchers in the project, rotating between three researchers. The focus groups were recorded and later transcribed verbatim, coded with Nvivo program, and analysed by the same researchers. All citations from the interviews are nominated by participant pseudonym, age, and gender (F or M).

## Results and discussion

The interviews on products that the informants were dissatisfied with showed that the faults often appeared within the liability period, but many consumers had not complained.

### *Evaluation of costs and benefits*

Large share of evaluations on whether to bother to start the complaint process are based on cost-benefit thoughts, as described by Grønhaug & Gilly (1991). The evaluations vary mainly between economic cost, time use and the needed effort, as well as the assessed probability of getting the complaint accepted.

Benny (66M): Yeah, I've been complaining so much lately, that you get tired of it. What I bought was on sale, so it didn't cost much, so sometimes it's almost worth just changing the jacket than complaining because… it is not really pleasurable to go and whine and complain. But I do it if I feel there is a need or I have to, or find it worthwhile. But I think that case is, I don't think it's worthwhile to complain so I'll just leave it at that. Just saving myself. Physically and mentally, so to speak (chuckles).
This also shows how the whole experience of complaining is felt as something unpleasurable, which the respondent prefers to avoid unless here is a strong need for it.

Two fathers discuss how they do not bother to spend time on complaining about cheap children's clothing.
Erik (33 M): And you can't be asked to spend the time on it if the price was 50 NOK [5 Euros].
Edgar (40 M): No, it costs more in road toll to get to the shop to complain than you paid for... It's pointless actually.

The evaluation of costs and benefits reduces the complaint rate, especially on low-cost products, such as many clothes or small electric appliances. The respondents also described how the effort got bigger when there were other practical issues connected, such as difficulty to transport large or heavy items.

Instead of complaining, some respondents also described that after some bad experiences, they turned to other retailers instead and chose an "exit" strategy (Hirschman, 1970). In such cases, it would have been profitable for the retailer to get information about the defective product, and get a possibility to retaliate the situation to keep the customers.

### *Knowledge*

There were several sources of confusion and a lack of knowledge concerning the legislation. In general, the extended liability period of five years was less known and created some confusion about which products it applies to, as expressed by Betty (48F): *I didn't know it was five years! I thought it was two years for everything*.

Some consumers linked this to price, rather than the product category. Previous survey research with a test question on mobile phones showed that only 34 % (and only 25 % of the women) believed that they had a right to redress after 3 ½ years (Strandbakken & Bøyum, 2017).

Another set of confusion was found between commercial producers' warranties and regulated consumer rights. A warranty is an agreement between the consumer and the manufacturer or retailer that in principle has to give consumers better rights than those provided by the regulations, although this rule is not always followed by the retailers.
